The following year Godin read a memoir to the ſame effect, accompanied by the ſame offer. It was not long before the king's conſent was obtained; and paſſports having been procured from the court of Spain, Condamine, Godin, and Bouguer embarked on this celebrated expedition at Rochelle, on the 16th of May, 1735.

No ſooner had this expedition left France than M. Maupertuis repreſented to the miniſter, the count de Maurepas, that a ſtill greater certainty would be obtained by meaſuring another degree, as near as poſſible to the pole. In conſequence of this, the academy received an order from the king to chooſe ſuch perſons as they ſhould think moſt proper, to carry this deſign into execution. The academicians appointed to make this celebrated voyage were Maupertuis, Clairault, and Monier; to theſe were added the Abbe Outhier, who poſſeſſed conſiderable ſkill in aſtronomical obſervations. They left France in the year 1736, and arrived at Tornea, a town ſituated at the northern extremity of the gulf of Bothnia, about the beginning of ſummer. The country deſtined to be the ſcene of this important operation is ſtrange and inhoſpitable beyond deſcription; and the entrance of ſcience into theſe dreary abodes, almoſt on the confines of the world, forms a contraſt ſo ſtriking, as to excite the moſt lively intereſt in the difficulties they had to encounter; nor do we think the reader will be diſpleaſed to find their narrative, and deſcription of the country, blended with the ſcientific account of their proceedings.

Their firſt deſign was to eſtabliſh their ſignals on the coaſt of the gulf of Bothnia; but this, from local circumſtances, was found impracticable. Fortunately, by following the courſe of the river Tornei, which runs nearly north and ſouth, the mountains on each ſide were found to afford many diſtant points of view, well adapted for the erection of their ſignals.

They ſet off from Tornea on the 6th of July, and began their journey by ſailing up the great river, which, riſing in the middle of Lapland, purſues its courſe to the gulf of Bothnia. From that day forward, their only habitation was the deſerts, and the ſummits of the mountains, which were to form their triangles.

They aſcended theſe with great difficulty, and erected on their tops ſignals, compoſed of large trees ſtript of their bark, and formed into hollow cones, which, from their whiteneſs, were viſible at 10 or 12 leagues diſtance.

The months of July and Auguſt were ſpent in exploring theſe mountains, erecting ſignals, determining the angles of the triangles, and chooſing a proper place for their baſe, the meaſurement of which they thought better to defer till all the other obſervations were finiſhed, which the approach of winter might have rendered impracticable. By referring to the map, *Plate* VI. *fig.* 53, it will be ſeen, that their triangles formed a heptagon. Kittis and Tornea were the extreme ſtations. Near the middle of the heptagon was placed the baſe line, having the advantage of a perfectly ſmooth level, as it was to be meaſured on the river itſelf as ſoon as the ſeverity of the cold ſhould have frozen its ſurface.

The angles of their triangles were meaſured on a quadrant of two feet radius, the centre being placed in the centre of the ſtation; the elevation or depreſſion of the adjoining ſignals was likewiſe obſerved, by which they could reduce the angles to the plane of the horizon.

The aſtronomical obſervations were finiſhed at Kittis by the latter end of September. The zenith diſtance of δ draconis was obſerved with a zenith ſector of nine feet radius, conſtructed in London by Graham; and the direction of the meridian with the ſignal at Pullingi was found, by obſerving the preciſe moment of time when the ſun paſſed the vertical. For this purpoſe they had a ſmall moveable tranſit inſtrument, the teleſcope of which was 15 inches. The axis of this being levelled, and the ſignal biſected, they obſerved the time by the clock, when the ſun's centre paſſed the vertical wire of the teleſcope; by calculating the azimuth of the ſun anſwering to the time of obſervation, the direction of Pullingi with the meridian line was found to be 28° 51′ 52″.

Having completed all that was neceſſary to be done at Kittis, they loſt no time in removing to Tornea, where they arrived the end of October. Here the ſame obſervations were repeated as had been at Kittis. The zenith diſtances of the ſame ſtar was obſerved, and the direction of the meridian eſtimated by the ſame method, as deſcribed above, differed about 30″ from the determination at Kittis.

The angles of the triangles, the amplitude of the arc, and the direction of the meridian being determined, nothing now remained but to meaſure the baſe. As this operation was conducted under peculiar difficulties, we ſhall give the account of it, as related by M. Maupertuis himſelf. "On Friday the 21ſt of December, the day of the winter ſolſtice, and a very remarkable one for ſuch an enterpriſe, we began the meaſure of our baſe towards Avaſaxa, where it lay. In this ſeaſon the ſun but juſt appeared above the horizon at noon; but the long twilight, the whiteneſs of the ſnow, and the meteors that are continually blazing in the ſky, afforded us light enough to work four or five hours every day.

"At eleven in the forenoon we left the curate's houſe, where we had taken up our abode till this operation ſhould be finiſhed, and went upon the river to begin our ſurvey, attended by ſo many ſledges, and ſo great an equipage, that the Laplanders, attracted by the novelty of the ſight, came down from the neighbouring mountains. We ſeparated into two bands, each of which carried four of the rods juſt mentioned. I ſhall ſay little of the fatigues and dangers of this proceſs. Judge what it muſt be to walk in ſnow two feet deep, with heavy poles in our hands, which were continually to be laid on the ſnow and lifted up again, in a cold ſo extreme, that whenever we wiſhed to taſte a little brandy, the only thing that could be kept liquid, our tongues and lips froze to the cup, and came away bloody:—In a cold that congealed the fingers of ſome of us, and threatened us with yet more diſmal accidents. While the extremities of our bodies were thus freezing, the reſt, through exceſſive toil, was bathed in perſpiration; brandy did not quench our thirſt, and therefore we were obliged to have recourſe to deep wells through the ice, which were ſhut almoſt as ſoon as opened, and from which the water could ſcarcely be conveyed unfrozen to our lips, and thus run the hazard of the dangerous contraſt which iced water muſt produce in our heated bodies."

The ſeverity of the climate, as above related, did not prevent them from completing the meaſurement of their baſe, with greater exactneſs than they had dared to hope for. They made uſe of eight deal rods, of 20 feet each in length; and their party, as above mentioned, being divided into two companies, taking four of theſe rods, each meaſured the ſame baſe, independently of the other. In the whole meaſurement of 7406 toiſes, only four inches difference was found between the two meaſures. The whole party now retreated to Tornea, where they ſpent the winter. Here they applied the meaſure of their baſe to their triangles, and found the arc, included between the parallels of Kittis and Tornea, to be 55,023½ toiſes, its amplitude being 57° 27′. This was nearly 1000 toiſes greater than it ſhould have been, according to the theory of Caſſini.

"The town of Tornea, at our arrival, on the 30th of December, had really a moſt frightful aſpect. Its houſes were buried to the tops in ſnow, which, if there had been any day-

light, would have effectually ſhut it out; but the ſnow continually falling, or ready to fall, commonly hid the ſun for the few moments that he might have been viſible at noon-day. In the month of January the cold was increaſed to that extremity, that Mr. Reaumur's mercurial thermometers, which at Paris, in the great froſt, 1709, it was thought wonderful to ſee fall 14 degrees below the freezing point, were now got down to 37. The ſpirit of wine in the others was frozen. If we opened the door of a warm room, the external air inſtantly converted all the vapour in it to ſnow, whirling it round in white vortices. If we went abroad, we felt as if the air was tearing our breaſts in pieces, and the crackling of the wood of which our houſes were made, as the violence of the froſt ſplit it, continually alarmed us with an approaching increaſe of cold. The ſolitude of the ſtreets was no leſs than if the inhabitants had been all dead; and in this country you may often ſee people that have been maimed, and had an arm or a leg frozen off. The cold, which is at all times very great, increaſes ſometimes by ſuch ſudden and violent fits, as almoſt infallibly to be fatal to thoſe who happen to be expoſed to it. Sometimes there riſe ſudden tempeſts of ſnow that are ſtill more dangerous. The winds ſeem to blow from all quarters at once, and drive about the ſnow with ſuch fury, that in a moment all the roads are loſt. Unhappy he who is ſurpriſed by ſuch a ſtorm in the fields; his acquaintance with the country, or the marks he may have taken by the trees, cannot avail him; he is blinded by the ſnow, and loſt if he ſtirs but a ſtep."

Though they had no reaſon to doubt the accuracy of their obſervations, yet that their truth might not be called in queſtion, they agreed on the return of ſpring to repeat the aſtronomical obſervations at Tornea and Kittis. δ Draconis was the ſtar which had been obſerved the preceding autumn for determining the amplitude of the arc. They now fixed on α in the ſame conſtellation; and it was obſerved during the months of March and April, at both the ſtations, as δ had been before. They now found the amplitude $57'\ 30\frac{1}{2}''$, which only exceeds the former determination $3\frac{1}{2}''$, Tornea not being exactly on the ſame meridian line as Kittis, but 31,495 toiſes to the eaſtward, a correction of 3.48 toiſes was applied to the mean amplitude, and the degree ultimately determined at 57,438 toiſes. Some minute corrections for refractions having been made by later aſtronomers, the degree of Maupertuis is uſually eſtimated at 57,420 toiſes. Notwithſtanding the diligent attention that was beſtowed by theſe aſtronomers on every part of the proceſs, later and more exact obſervations have ſhewn, that their obſervations were affected with ſome conſiderable error. It is conjectured that the inaccuracy originated in the zenith obſervations with the ſector. The degree, as determined above, is too long by above 200 toiſes, according to the late meaſurement of the Swediſh aſtronomers. This correſponds to an error of 10″ in the amplitude of the arc. This quantity exceeds what we ſhould have thought probable, and unfortunately it was found that Maupertuis had not deſcribed his ſtation with ſufficient preciſion, to enable thoſe who wiſhed to verify his operations, to repeat the obſervation on the identical points that had been formerly choſen by the French aſtronomers.

We have now to return to the ſouthern expedition, which, as we have already ſtated, ſailed from France in the ſummer of the year 1735. After making ſome ſtay at St. Domingo, they proceeded by way of Carthagena to Porto Bello, croſſed the iſthmus which ſeparates the two continents, and embarking at Panama, arrived at Manta on the coaſt of Peru, in the month of March, 1736. At this place the party ſeparated, and afterwards arrived by different routes at Quito. They had been joined at Carthagena by Don George Juan, and Don Antonia Uiloa, marine officers in the Spaniſh ſervice, who were ordered by the king of Spain to facilitate the labours of the French academicians by all the aſſiſtance in their power to give. The difficulties which preſented themſelves on the firſt ſurvey of the country were even more formidable than thoſe which had occurred in the expedition to the north. The ſummits of the lofty mountains on each ſide the plains of Quito are not only covered with perpetual ſnow, but almoſt always obſcured by miſt or clouds. Nothing but the moſt ardent zeal for the ſucceſs of their enterprize could have enabled them to have perſevered in ſo unpromiſing a taſk. Succeſs was not abſolutely impoſſible, and this was thought ſufficient encouragement to perſevere. It was often neceſſary to wait for weeks at a ſtation to get a favourable opportunity of viewing the ſurrounding country; and when this occurred, they found perhaps that their ſignals had diſappeared, either overturned by the violence of the hurricanes, or ſtolen by the neighbouring Indians. The Spaniſh government did not ſeem diſpoſed to render them ſuch efficacious aſſiſtances as they were entitled to expect from the nature of their miſſion, and we perceive with regret from their reſpective accounts, that there was a want of that union and cordiality among themſelves ſo neceſſary to enable them to proſecute with cheerfulneſs ſo laborious an undertaking.

With theſe difficulties and vexations, they ſtruggled eight years before their operations were completed; and it was nearly ten years after their departure from France, before they returned with the fruit of their labour.

We ſhall now give, as briefly as poſſible, an outline of their operations.

When they arrived at Quito, their firſt care was to ſelect a ſpot for the meaſurement of a baſe, and they were rather fortunate on meeting with a tolerably level ſituation, in a plain called Yarouki in New Quito. The party divided into two, Godin with Don George Juan, and Bouguer with Condamine. Theſe each meaſured the baſe 6272 toiſes, and the difference of the meaſures did not exceed two inches.

Some difficulties occurred in meaſuring the baſe, but they were nothing compared to thoſe they encountered in conſtructing the triangles. The whole country conſiſting of mountains, ſome covered with perpetual ice, others, leſs lofty, almoſt conſtantly enveloped in ſnow and miſt. This operation was not completed for two years: Godin and Don Juan finiſhed their triangles at Cuença, but afterwards prolonged them to Pueblo veijo de Mira, about $\frac{1}{2}$ a degree to the ſouth, the whole arc being near $3°\frac{1}{2}$.

The arc meaſured by Condamine and Bouguer was not quite ſo long; it extended by the medium of 32 triangles from the equinoctial line beyond the third degree of ſouth latitude. The extreme ſtations were Cotcheſqui on the north, and Tarqui on the ſouth. A baſe of verification was meaſured at the ſouthern extremity of 5259 toiſes, which agreed within a toiſe of its calculated length. The meaſure of Godin and the Spaniſh officers was put to the ſame teſt by a ſimilar verification of a baſe meaſured on the plain of Cuença.

The reſt of the operation was likewiſe conducted by ſeparate parties. Bouguer and Condamine having finiſhed their trigonometrical meaſurements, commenced their obſervations for determining the amplitude of the arc. Their efforts to obtain a ſatisfactory coincidence were for a long time ineffectual. Their ſector of 12 feet radius met with frequent derangements, and the length of time neceſſary for its removal from one extreme ſtation to the other rendered the obſervations very diſcordant; for at that time the

theory

theory of aberration and nutation was not known. Their ſector proving defective, they were obliged to alter its conſtruction, and after much loſs of time, they adopted the expedient of conſtructing a new one, and obſerving at the ſame time at each ſtation. They now began to have greater confidence in their operations, and by repeated obſervations of the diſtance of ε Orionis, obſerved at Tarqui and Cotcheſqui, they determined the intercepted arc to be 3° 7′ 1″, and the meaſure of a degree 56,750 toiſes. Godin and the Spaniſh officers undertook likewiſe on their part a ſeries of ſeparate obſervations, to determine the amplitude of the arc between Mora and Cuença. But the latter, being ordered on profeſſional duty, quitted the party for a period of two years, during which Godin continued to obſerve alone. When the Spaniſh officers returned, they completed their operations, ſo that, in fact, there were three determinations obtained depending very little on each other; the latter determination gave the amplitude between Mora and Cuença 3° 36′ 52″, and the degree 56,768 toiſes.

Bouguer ſet off firſt on his return to Europe; he followed nearly the ſame route by which he went, and arrived in France, June 1744. He publiſhed a very full and detailed account of his operations in one large quarto volume, "La figure de la Terre:" a book containing many valuable diſquiſitions, both aſtronomical and phyſical, with a learned inveſtigation of ſeveral problems relative to the figure of the earth.

Condamine purſued his journey to Europe over a large tract of country, almoſt unknown. He traverſed the whole of the continent of South America, deſcending the river of the Amazons, to the Portugueſe ſettlements. He was thus enabled to contribute moſt uſefully to our geographical knowledge of that country, of which the moſt imperfect and fabulous accounts only had been publiſhed. He arrived in France in the year 1745. Beſides various memoirs preſented to the academy, and which are to be ſeen in their memoirs, he publiſhed in three volumes, quarto, a very full account of every circumſtance that had taken place, not only relating to the great work in which he had been engaged, but alſo his own adventures, and obſervations on the nature of the country, and its inhabitants, climate, natural hiſtory, &c. His work is divided into two parts; one, "Introduction Hiſtorique," containing the hiſtorical part of this intereſting voyage, written in a moſt pleaſing and animated ſtyle; the other, "Meſure des trois premiers Degrees du Meridien," is dedicated to the obſervations immediately relative to the object of the expedition.

The two Spaniſh officers returned by the way of Cape Horn, and arrived in Spain in 1746. Don Antonia de Ulloa was taken by the Engliſh in his paſſage, and brought to London, where he was treated with all the reſpect due to his character as a man of ſcience. He was admitted a fellow of the royal ſociety, and all his papers were reſtored to him. On his return to Spain, in conjunction with Don Juan, he publiſhed an account of their voyage in three quarto volumes, which was afterwards tranſlated into French, and printed at Amſterdam, in two volumes, quarto. This work, like that of Condamine, is extremely intereſting, containing a great variety of amuſing matter, beſides the account of their own operations, relative to the meaſure of the meridian.

Godin, after having been detained by various occupations in Peru, till 1748, and witneſſing the dreadful cataſtrophe which deſtroyed the two cities of Callao and Lima, ſet off on his journey towards Europe. He traverſed the wide extended provinces of Peru, Tucuman, and Paraguay, and arrived at Buenos Ayres, from whence he returned to France through Portugal and Spain. The king of Spain, in whoſe ſervice he had held ſome employ during his reſidence in Peru, appointed him director of the royal marine academy at Cadiz. At this place he had the misfortune to loſe his ſight, which prevented him from giving any relation of his own, as the other academicians had done, which is much to be regretted, as he is ſaid to have poſſeſſed much valuable information. His brother Godin des Ordonnois accompanied him. He married whilſt in the country, and travelled to Paraguay, from which place he ſent to his wife to join him. She, with her brothers and family, were to traverſe the continent, as Condamine had done before, by the river of the Amazons. The whole party loſt themſelves in the immenſe deſerts of South America, and madam Godin, after ſeeing her brothers and moſt of her attendants periſh one by one with hunger and fatigue, arrived after a journey of unparallelled diſtreſs and danger ſafe at her deſtination. Her ſingular adventures are related in a ſmall work publiſhed by Condamine in 1773, entitled, "An Account of the Fate of the Academicians and their Aſſiſtants, who were employed in the Expedition to Peru."

Juſſieu, the botaniſt, having ſtaid ſome time after the departure of his companions, to increaſe his collection of plants, and other objects of natural hiſtory, returned to France, but publiſhed no ſeparate account of his voyage. Seniergue, their ſurgeon, was aſſaſſinated at Cuença, during the celebration of a bull feaſt.

Three different meaſures had now been obtained with great labour and difficulty at the equator, in the latitude 45°, and at the arctic circle, and no doubt any longer remained as to the oblate figure of the earth; it was univerſally admitted that the equatorial exceeded the polar axis by a conſiderable quantity, but the exact ratio between the two was very far from being accurately aſcertained. It became evident that ſome conſiderable error had been committed in the meaſurement formerly made in France. The aſtronomers who had returned from the northern expedition, conjointly with other members of the academy, undertook a re-examination of Picard's operations. They employed the ſame ſector as in Sweden, and by a careful compariſon of the zenith diſtances of ſeveral ſtars obſerved at Paris and Amiens, they found it neceſſary to correct the amplitude of the arc determined by Picard, by a quantity amounting to about 6″. But about the ſame time it was diſcovered, that an error exiſted in the baſe of Picard, of about one toiſe in a thouſand. This was ſuppoſed to ariſe from the non-identity of the meaſures, and not from want of care on the part of Picard. It ſo happened that theſe errors nearly compenſated each other, ſo that Picard's determination ſtill remains very near the truth. To diſcover the errors that were thought inevitably to exiſt in the great meridian between Perpignan and Dunkirk, it was reſolved to undertake this great work a ſecond time: it is the leſs neceſſary to enter into the details of this operation (known by the name of Le Meridien verifié), as it has been again re-meaſured within theſe few years paſt, with a degree of preciſion that would have appeared incredible to the aſtronomers formerly employed in the ſame operation. We ought, however, to mention that Caſſini de Thury and La Caille undertook a complete reviſal of all the former triangles, meaſured two new baſes, divided the arc into four parts of about $2°\frac{1}{2}$ each, and found that the degrees increaſed as they approached the north, but not according to any law that could be deduced from any probable theory. Thére were ſome other meaſures of a degree made about that period, that deſerve to be mentioned: La Caille, at the Cape of Good Hope, meaſured an arc of the meridian, and found the degree in latitude 33° 18′ ſouth = 57,037 toiſes. As La Caille was furniſhed with very imperfect inſtruments, we ſhall enter into no further detail of theſe operations,

which

which are deſcribed at large in the memoirs of the academy for 1751. About the ſame period, Boſcovich, a learned Jeſuit, and celebrated mathematician, meaſured an arc of two degrees between Rimini and Rome, in latitude 43°, and found the degree = 56,973 toiſes. The whole of this operation is minutely deſcribed in a quarto book, publiſhed at Rome in 1755, "De Litterariâ Expeditione per Pontificam Ditionem ad Dimetiendos duos Meridiani Gradus," &c.

A tranſlation of this work appeared in 1770. It contains inveſtigations of ſeveral problems relating to the figure of the earth.

Meſſrs. Maſon and Dixon meaſured a degree of the meridian in America, a full account of which is to be found in the Phil. Tranſ. 1768. Their mode of meaſurement differed from all others in this; that inſtead of adopting the method of triangles, the whole ſpace was actually meaſured. From this meaſurement the degree in latitude 39° 12′ appeared to be 56.888 toiſes.

In 1777, Beccaria undertook a ſimilar operation in the plains of Piedmont, the reſult of which gave 57,024 toiſes for the length of a degree, in latitude 44° 44′. Gradus Taurinenſis, quarto, 1774. Pere Lieſganig, a Jeſuit, meaſured two degrees, one in Hungary, in lat. 45° 57′, which gave 56,881, the other in Auſtria, lat. 48° 43′. 43 = 57,086.

The following account of the meaſurement of a degree of latitude in China is taken from the German Muſeum, the 9th number, Auguſt 1800.

"In the month of December 1702, father Anthony Thomas, a Jeſuit, was ordered by the emperor Kanghy to meaſure a degree of latitude. For that purpoſe, a very extenſive plain was choſen, and the buſineſs of meaſuring carried on in the preſence of all the mandarins of the mathematical tribunal, and even of one of the ſons of the emperor, who wiſhed to be an eye-witneſs of the operation. The reſult was, that 1° 1′ 32″, the part of the meridian they meaſured, comprehended exactly 200 Chineſe ſtadia, at 360 geometrical paces each, conſequently 1°, 70,206 paces. The proportion of the Chineſe foot to the old Roman foot, according to Villalpando, is ſtated by the Jeſuits to be 16 : 15; which makes 74,886 geometrical paces, as meaſured by the Roman feet, and reduced to French toiſes by the proportion of 1440 : 1315, gives 56987.9 toiſes. This curious piece of geographical intelligence has been taken from a letter of father Caſparus Caſtner, a German Jeſuit, to father Francis Schuck, of the ſame order, at Munich, dated Rome, January 10th, 1705, communicated to Major de Zach, at Gotha, as late as April 19, 1800, by Mr. Gabriel Knogler, profeſſor at Ingolſtadt. It is a pity that neither the degree of latitude, nor the method of meaſuring, is pointed out in this communication. From circumſtances, however, it may be inferred, that a meaſurement, at which the whole mathematical court and the emperor's ſon himſelf attended, was performed not far from Pekin. And as they had taken their meaſures on an extenſive level ground, and proceeded as far as 200 ſtadia, it may be concluded that the mode of menſuration they adopted was to meaſure from one end to the other of a ſtraight line, extended to that number of ſtadia. If this, as it appears, has really been the caſe, it is aſtoniſhing how a method ſo tireſome in its nature, and ſo imperfect in its principles, could give a reſult by which the meaſurement in queſtion may claim a rank among the moſt exact operations of this kind, performed with better inſtruments, and on more accurate principles."

When we conſider how important it muſt have been to the learned Jeſuits at the court of Pekin, that no great error ſhould be committed in this operation, we ſhould not be ſo much ſurpriſed at the accuracy of the reſult, which moſt probably was very little connected with the correctneſs of the proceſs.

We have omitted to mention the meaſure of a degree of longitude, by Caſſini and La Caille, in the latitude of 43° ½.

One obſerver placed on mount St. Victoire, near Aix, the other on a mountain near Cette, obſerved ſeveral times the moment of exploſion of 10lbs. of powder upon the church of St. Marie, a little village on the banks of the Rhone.

By a baſe meaſured near Arles, they found the diſtance 1° 55′ 19″ = 41,358 toiſes. It would have been 260 toiſes leſs on the ſpherical hypotheſis.

Notwithſtanding theſe labours, great uncertainty ſtill remained reſpecting the true figure of the earth: the different meaſures could by no means be made to agree with any probable hypotheſis. The ellipticity reſulting from theſe meaſures varied from $\frac{1}{150}$ to $\frac{1}{300}$.

It ſeemed difficult to decide whether this diſcordance aroſe from irregularity in the figure of the earth, or from errors in the meaſurement. We now know that both theſe cauſes concurred to produce this diſagreement. Later and more exact ſurveys have taught us that the plumb line is affected by great irregularities; and that the determination of the true figure of the earth by actual meaſurement, is an operation of much greater difficulty than was at that time imagined.

Account of the trigonometrical Operations carried on in England.

Soon after the peace of 1783, a project was undertaken for connecting the obſervatories of Greenwich and Paris, which gave riſe to the conſtruction of two inſtruments, ſo greatly excelling any that had been previouſly uſed in geodetical operations, that they abſolutely form a new era in the ſcience of trigonometrical ſurveying. One of theſe was the theodolite of Ramſden, the other the repeating circle of Borda. (For a particular deſcription of each, ſee THEODOLITE and CIRCLE.)

The great trigonometrical ſurvey of this kingdom originated in a great meaſure from a memorial of Mr. Caſſini de Thury, tranſmitted by the French ambaſſador to Mr. Fox, then ſecretary of ſtate, ſetting forth the advantage that aſtromony would derive from conſtructing a ſeries of triangles that ſhould connect trigonometrically the two obſervatories of Greenwich and Paris, and thus determining their relative poſitions, more accurately than it was ſuppoſed could be done by aſtronomical obſervation.

Both nations were at that time enjoying the bleſſings of peace, and the learned men of each country readily obtained from their reſpective governments, the aſſiſtance and patronage which ſuch an undertaking required. The execution of the plan on the Engliſh ſide of the channel was committed to the ſuperintendance of general Roy, who had long been eminent in his profeſſion as a ſkilful engineer, and had been much engaged in purſuits of this kind, though on a ſmaller ſcale, chiefly with a view to his own amuſement.

The firſt conſideration was to find an appropriate place for the meaſurement of a baſe; and Hounſlow-heath was ſelected for that purpoſe, both from its great extent, and the evenneſs of its ſurface.

On the 16th April, 1784, the preſident of the royal ſociety, ſir Joſeph Banks, accompanied by ſeveral others of its members, attended the firſt examination of this place, and they had the ſatisfaction to find that a ſtraight line might be drawn with little difficulty from King's-Arbour on the N.W. extremity of the heath, to Hampton poor-houſe, on the S.E. extremity, a diſtance of above five Engliſh miles. It ſo happened that this line coincided with a remarkable ſpire ſeen at the diſtance of 10 or 12 miles, known afterwards to belong to Banſtead church. This object was of conſiderable

uſe

uſe in clearing the baſe line, which was done by a party of ſoldiers, who removed the bruſh wood and other inequalities of the ſoil, in a tract of about three yards in breadth.

Various methods were ſuggeſted, and tried for the meaſurement of the baſe, as on the accuracy of this delicate operation all the ſubſequent deductions would depend. Deal rods were firſt employed, and afterwards abandoned, as they were found to be affected by the moiſture and dryneſs of the air, in a manner not eaſily reducible to rule. Glaſs rods were ſubſtituted inſtead of them, and ultimately adopted. Pyrometrical experiments were inſtituted to aſcertain the exact law of their variation from heat and cold. The extremities of the baſe were marked by two pipes, and afterwards by cannon. The line joining them was meaſured through the air, and not by a ſucceſſion of level lines of unequal altitudes, as had been uſually practiſed in other countries. The inclination of this hypothenuſal line to the horizon was meaſured by a proper inſtrument, and the requiſite correction applied.

The firſt meaſurement of the baſe with the glaſs rods gave for its total length 27404.08 feet.

In the year 1791, this baſe was meaſured a ſecond time, with a ſteel chain of exquiſite workmanſhip, conſtructed by Ramſden, and this meaſurement gave 27404.315 feet, differing but $2\frac{3}{4}$ inches from the former. The ſtandard meaſure uſed on this occaſion was taken from a braſs ſcale 42 inches in length, in the poſſeſſion of the royal ſociety. A baſe of verification was likewiſe meaſured on Romney-marſh, in the ſame manner as had been done on Hounſlow-heath, except that the ſteel chain was ſubſtituted for the glaſs rods.

The length of this baſe, after all the requiſite reduction, was 28,535 feet, 8.128 inches.

The theodolite deſtined to meaſure the angles ſurpaſſed, as we have before mentioned, in its dimenſions and elaborate workmanſhip, every inſtrument of the kind that had been ſeen in Europe; it meaſured angles with ſuch preciſion, that it became neceſſary, in the calculation of the triangles, to take into conſideration the exceſs of three ſpherical angles above two right angles, a quantity that had hitherto been too minute to be aſcertained by any inſtrument, and was only known by theory to have an exiſtence. The amount of the total error in the ſum of the three angles never exceeded $3''$, ſo that the angles generally muſt have been meaſured to the neareſt ſecond. A portable obſervatory, and portable ſignals, were likewiſe uſed in this ſurvey, ſo that the centre of the theodolite was conſtantly brought into the very point, which was to conſtitute the ſignal from the next ſtation; by which means all the troubleſome corrections, which we ſhall have occaſion to notice in the French ſurvey, were avoided, and all cauſe of error ariſing from them entirely removed.

As the ſituation of Paris, with reſpect to Dunkirk, had been ſettled by former operations, the only part of this proceſs that required the co-operation of French aſtronomers, was to continue the triangles from Dover to Dunkirk. This was undertaken by Caſſini, Mechain, and Le Gendre, men of deſerved celebrity, and members of the academy of ſciences. It was by them that the firſt trial was made with the repeating circle. The one they uſed on this occaſion was only twelve inches diameter, and the firſt that had been conſtructed; yet it is beyond a doubt, but that the angles taken with it differed but little in exactneſs from thoſe obſerved with the theodolite. The latter was certainly the ſuperior inſtrument, but it was large and of difficult tranſport; whereas the French inſtrument went into a ſmall box, which the aſtronomers carried with them in their voiture.

The inſtrument was ſucceſſively carried to twenty-three different ſtations, which were diſtinguiſhed into two ſets; the firſt were permanently marked by pipes ſunk in the earth, the others were thoſe where the inſtrument was elevated to the top of ſome tower, ſteeple, or other building.

The ſtations of the firſt ſet marked with pipes are fourteen in number, *viz.*

Hampton poor-houſe, } the extremities of Hounſlow-heath baſe.
King's-Arbour, }
St. Ann's-hill, about the middle of the eaſt edge.
Hundred-acres, near the weſt end of the garden.
Norwood, towards the Croydon end of the heights.
Botley-hill, in a field belonging to Simpsfield-Lodge farm.
Wrotham-hill, in a field belonging to Mr. Johnſton.
Hollingborn-hill, in a field belonging to Mr. Duppa.
Fairlight-down, 347 feet ſouthward from the windmill, which makes with Fairlight church an angle of 105° 53′ 20″.
Ruckinge, } the extremities of the baſe of verification.
High-Nook, }
Allington-knell, an artificial mount belonging to ſir John Honeywood.
Paddleſworth, eaſtward from the church in the broomfield belonging to Mr. Brockman.
Folkſtone turnpike, weſtward from the public houſe.

The ſtations of the ſecond ſet, where the inſtrument was elevated on buildings, are nine in number.

Hanger-hill tower.
Tranſit room of Greenwich royal obſervatory.
North-weſt turret of Sevendroog caſtle, on Shooter's-hill.
Swingfield church ſteeple.
North turret of the ſteep of Dover caſtle.
Lydd ſteeple.
Tenterden ſteeple.
Goodhurſt ſteeple.
Frant ſteeple.

The ſtations on the French ſide were,

Montlambert.
Calais.
Blancnez.
Fiennes.
Watten.
Mount Caſſel.
Dunkirk.

The direction of the ſides of the triangles was determined by placing the theodolite over the tranſit inſtrument at Greenwich, and obſerving the angle which the meridian mark made with the next ſtation.

When theſe were corrected, they found 37 triangles, as repreſented in *Plate* VIII., the ſides and angles of which were obſerved and calculated as follows:

Baſe at Hounſlow-heath meaſured with glaſs rods - - -	27404.01 feet.
By meaſurement with a ſteel chain in 1791 - - -	27404 32
Mean length - -	27404.2

The reſult, independent of theory, as far as relates to the immediate object of the undertaking, is, that the diſtance between the parallels of latitude of Greenwich and Paris is 160,659 fathoms, or 963.954 feet, which correſponds to an arc of 2° 38′ 26″, which gives the length of a degree of the meridian in the latitude 50° 10′, equal to 60,843 fathoms. The perpendicular diſtance of the tower of Dunkirk being 547,058, and Dunkirk 9080 feet eaſt of the meridian of Paris, the diſtance of the meridians of Greenwich and Paris, reckoned on the parallel (to the perpendicular) paſſing through Dunkirk, is 537,978 feet. With reſpect to the difference of longitude, ſome uncertainty ſtill exiſts, which it is not eaſy to remove. The French aſtronomers, calculating from a general hypotheſis of the figure of the earth, make it 9^m 21″ of time. But colonel Mudge, by aſſuming a partial hypotheſis, adapted to the intermediate country, and ſuch as reſults from actual meaſurement, makes the difference of longitude 9^m 19″.4: the latter determination certainly appears to us to be far the moſt probable; the truth is, perhaps, between both. Dr. Maſkelyne, from aſtronomical obſervation, eſtimates it 9^m 20″, and nearer than this it will probably never be known.

Meaſurement of a Degree perpendicular to the Meridian.

The object of Caſſini's memoir, relative to the junction of Greenwich and Paris, being thus accompliſhed, the further proſecution of the ſurvey was ſuſpended for a long time by the death of general Roy; but the duke of Richmond, then maſter of the ordnance, having, by an accidental circumſtance, obtained from Ramſden a new theodolite of the ſame dimentions as that above noticed, but with conſiderable improvements, and two new ſteel chains, by the ſame artiſt, his Grace availed himſelf of the influence his ſituation commanded, and procured the king's permiſſion for the recommencement of the ſurvey, which has ſince been extended to the remoteſt parts of the kingdom. On the death of general Roy, the care of conducting this great work was entruſted to colonel Mudge, who had already diſtinguiſhed himſelf by his ſuperior talents, and who has executed the arduous taſk committed to his charge in a manner that ſhews him to have been moſt eminently qualified for the undertaking.

He was for ſome time aſſiſted by Mr. Dalby, a mathematician of conſiderable reputation, who has contributed many valuable theorems relative to the object of their purſuit, but who was obliged by ill health to relinquiſh his employment.

The greater part of theſe operations we conſider as quite foreign to our preſent ſubject; but two objects which immediately relate to it, have been accompliſhed in the courſe of this ſurvey, Theſe are the direct meaſurement of an arc of the meridian, and of a degree of a great circle perpendicular to it.

The latter operation might be made the ſubject of a ſeparate article, but as it occurred firſt in order of time, and as the two meaſurements had the baſe and ſeveral triangles in common, we prefer making it the firſt ſubject of our conſideration.

The operations of 1791 began by a re-meaſurement of the baſe, with the ſteel chains, and, as we have already ſtated, a difference of only 2¾ inches was found between the two meaſures.

New ſtations were choſen to extend the ſurvey weſtward, and to unite Dunnoſe and Beachy-head with the former triangles. Theſe ſtations were choſen to meaſure the perpendicular degree, as they were nearly eaſt and weſt of each other, and were in favourable weather reciprocally viſible, though more than 60 miles diſtant. Some of the ſides of the former ſeries of triangles being common to the new, an opportunity occurred of judging of the accuracy of the two meaſurements; and the ſide of a triangle of near forty miles in length was not found to differ in the new ſurvey but 16 inches from the length computed in the former one.

A baſe of verification was meaſured on Saliſbury-plain, the length of which was reduced to the ſame level as that on Hounſlow-heath = 36,574.4 feet. One branch of this ſeries of triangles towards the weſt was conſtructed almoſt entirely for the purpoſe of connecting this new baſe with the original baſe of departure on Hounſlow-heath, and the length deduced by calculation did not differ an inch from the actual meaſurement.

Three other principal branches of the triangle ſerved to connect Dunnoſe and Beachy-head with the baſes, and with the former triangles of general Roy. So that the diſtance from Dunnoſe to Beachy-head was determined by four different computations, and appeared to be as follows:

339·394.6
339·395.0
339,399.2
339 401.5 } mean 339,397.6 = diſtance of Dunnoſe and Beachy-head.
= 64.28 miles.

The azimuthal angle at Dunnoſe was found by obſervations of the Pole Star to be - - - 81° 56′ 53″
and at Beachy-head - - - 96 55 58

Let

Let P G M (*Plate* VII. *fig.* 56.) be the meridian of Greenwich; then if M B be the parallel to the perpendicular at G, Greenwich, we have M B = 58,848 feet, and G M = 269.328 feet. Therefore, taking 60,851 fathoms for the length of the degree on the meridian, as derived from the difference of latitude between Greenwich and Paris, applied to the meaſured arc (ſuppoſing the latitude of Paris 48° 50′ 14″), we get G M = 44′ 15″.26, conſequently the latitude of the point M (that of Greenwich being 51° 28′ 40″) is 50° 44′ 24″.74, and the co-lat. P M = 39° 15′ 35″.26.

With reſpect to the arc M B, for the preſent purpoſe it is not of conſequence on what hypotheſis it be obtained. But if 61,173 fathoms be aſſumed for the length of a degree of a great circle, perpendicular to the meridian at M, then M B = 9′ 37″.19, and the latitude of B, Beachy-head, will be found 50° 44′ 23″.71.

Again (*fig.* 57.), let W B be the arc of a great circle perpendicular to the meridian of Beachy-head, at B, meeting that of Dunnoſe in W, and let D R be another arc of a great circle perpendicular to the meridian of Dunnoſe in D, meeting that of Beachy-head in R: then we ſhall have two ſmall ſpheroidical triangles W B D and R B D, having in each two angles given, namely, W D B = 81° 56′ 53″, and W B D = 6° 55′ 58″, in the triangle W B D; and D B R = 83° 4′ 2″ with B D R = 8° 3′ 7″, in the triangle D B R; and theſe reduced to the angles formed by the chords, give the following triangles for computation; namely,

In the triangle W B D	W B D =	6°	55′	57″.2
	W D B =	81	56	52.4
	D W B =	91	7	10.4
In the triangle B D R	B D R =	8°	3′	6
	D B R =	83	4	1
	D R B =	88	52	53

In which it muſt be noted, that the reduced angles are given to the neareſt $\frac{1}{4}$″.

Again, let B I and D E be the parallels of latitude of Beachy-head and Dunnoſe, meeting the meridians in L and E: then to find L W and E R, we have two ſmall triangles, that may be conſidered as plane ones, namely, L B W and E D R, in which the angles at W and R are given nearly.

Now the exceſs of the three angles above 180° in the triangle D B W, conſidered as a ſpherical one, is 3″ nearly. Therefore the angle D W B will be 91° 7′ 12″ nearly. Hence B W L = 88° 52′ 48″, conſequently B L W = 90° 33′ 36″, and L B W = 0° 33′ 36″. Therefore with the chord of the arc W B = 336,115.6 feet, we get W L = 3285.2 feet, which added to W D, as found above, gives 44,258.6 feet, for the diſtance between the parallels of Beachy-head and Dunnoſe. Again, in the triangle D B R, conſidered as a ſpherical one, the exceſs is about $3\frac{1}{2}$″.

Hence, from the two obſerved angles at D and B, namely, 8° 3′ 7″, and 83° 4′ 2″, we get the third angle B R D = 88° 52′ 54″.5, and taking the triangle E R D as a plane one, the other angles will be 0° 33′ 32″.75 (E D R), and 90° 33′ 32″75 (D E R); therefore with the chord of the arc D R = 336,980 feet, we get R E = 3288.2 feet, which taken from B R as found above, leaves 44,258 9 feet for the meridional arc or the diſtance between the parallels of Beachy-head and Dunnoſe, which is nearly the ſame as before.

This method of determining the diſtance between the parallels is ſufficiently correct. But the ſame concluſion may be deduced from a different principle, thus:—

Let the difference of longitude, or the angle at P, be found on any hypotheſis of the earth's figure, and likewiſe the latitudes of Beachy-head and Dunnoſe; with theſe compute the latitudes of the points R and W: then it will be found that the arc R E is $\frac{5}{1000}$″ greater than L W, and $\frac{1}{1000}$″ on the meridian is nearly a foot, R E is 5 feet more than L W. Hence $\frac{47547.1 - 5 + 40973 4}{2} = 44257.8$ is the diſtance between the parallels, which is very nearly the ſame as found by the other method. It ſeems, therefore, that whatever be the value of the arc between theſe parallels in parts of a degree, the diſtance between them is obtained ſufficiently near the truth. Therefore, taking 60 851 fathoms for the length of a degree on the meridian, we get the arc ſubtended by 44,258.7 feet = 7′ 16″.4, which ſubtracted from the latitude of Beachy-head, namely, 50° 44′ 23″.71, leaves 50° 37′ 7″.31 for the latitude of Dunnoſe. We have, therefore, for finding the length of the degree of a great circle perpendicular to the meridian at Beachy-head or Dunnoſe, the latitudes of the two ſtations, and the angles which theſe ſtations make with each other and the pole.

Since the ſum of the horizontal angles P D B + P B D (*Plate* VII. *fig.* 55.) is nearly the ſame as the ſum which would be found on a ſphere, we ſhall find the angles for ſpherical computation, as follows:—The co-latitudes of D and B, or the arcs D P and B P, are 39° 22′ 52″.69, and 39° 15′ 36″.29; therefore half their ſum is 39° 19′ 14″.49, and half their difference 3′ 38″.2. —Half the ſum of the angles P D B and P B D is 89° 26′ 25″.5; therefore as tang. 39° 19′ 14″.49 : tang. 3′ 38″.2 : : tang. 89° 26′ 25″.5 : tang. 7° 31′ 57″.71, or half the difference of the angles. Hence the angles for computation are 81° 54′ 27″.79 and 96° 58′ 23″.21, which with the co-latitudes of D and B give the difference of longitude between Beachy-head and Dunnoſe, or the angle D P B = 1° 26′ 47″.93. We have now two right angled triangles (*fig.* 57.), which may be conſidered ſpherical, namely, P B W and P D R, in which the angle at the pole, P, is given, and likewiſe the ſides P B and P D; therefore uſing theſe data, we find the arc B W = 54′ 56″.21, and the arc D R = 55′ 4″.74. The chords of the two perpendicular arcs are about $3\frac{1}{2}$ feet leſs than the arcs themſelves: therefore B W = 336,119.1 feet, and D R = 336,983.5 feet. And by proportioning theſe arcs to their reſpective values in fathoms, we get the length of the degree of the great circle perpendicular to the meridian in the middle point between W and B = 61,182.8 fathoms, and in the middle point between R and D = 61,181.8 fathoms. Therefore 61,182.3 fathoms is the length of a degree of the great circle perpendicular to the meridian, in latitude 50° 41′, which is nearly that of the middle point between Beachy-head and Dunnoſe.

Of the Meaſurement of an Arc of the Meridian between Dunnoſe in the Iſle of Wight, and Cliſton in Yorkſhire.

The account of this important part of the Engliſh ſurvey was drawn up by colonel Mudge, and read before the royal ſociety in June 1803.

The length of the meaſured arc was more than 196 Engliſh miles. The triangles extended along a line exactly north and ſouth. They were conſtructed, and obſerved in the ſame manner as in the former part of the ſurvey, and depending on the ſame baſes, namely, Hounſlow-heath and Salisbury-plain. But, to add greater ſecurity to the northern triangles, a baſe was meaſured on Miſterton Car, near the northern extremity of the baſe, with the ſame chains, and with equal care, as in the former operations. This was the fourth baſe that had been meaſured; and though it would not have been prudent to have omitted ſo eſſential a verification, yet, had all the calculations been

made

made from one alone, the difference in the results would hardly have been ſenſible. The length of the baſe on Miſterton Car was 26,342.7 feet.

Colonel Mudge thus ſtates his reaſons for ſelecting this arc in preference to any other.

"In a country, whoſe ſurface throughout its whole extent is equally diverſified with hilly ground, that particular part of it ſhould be choſen for carrying on a meridional meaſurement which comprehends the moſt extenſive arc.

"This ariſes from the neceſſary conſequence which attends an operation in a country ſo circumſtanced; as poſſibly no ſpot fixed on for a place could be ſuppoſed free from the effects of unequal attraction in the adjoining matter.

"In ſuch a country, therefore, a meaſurement upon the moſt extenſive arc muſt give the moſt accurate concluſion; for the errors ariſing from the cauſe here mentioned, like thoſe of obſervation, leſſen in their effects, on their application to arcs of greater magnitude.

"If Great Britain were a country thus diverſified, the moſt eligible part would be that where the meridian from Lyme in Dorſetſhire paſſes northward into Scotland.

"The difference of latitude between that place and Aberdeen, near to which that line cuts its parallel, is 4° 47′ nearly.

"But, however great the advantages attending ſuch a length of arc might be, under the general circumſtances of accurate terreſtrial meaſurement, and accurate obſervations at its extremities, no beneficial conſequences could be expected to attend the placing of the ſector at intermediate ſtations; as the arc would be found running, almoſt every where, through a country abounding with hills, conſiderable both in magnitude and number.

"Under this conſideration, I determined to meaſure a portion of the meridian which proceeds from Dunnoſe to the mouth of the Tees, becauſe, from inquiry, I had reaſon to ſuppoſe it the longeſt meridional arc in Britain, free from any apparent obſtruction. And I was led to ſelect Dunnoſe for one of its extremities, as obſervations made there, in conjunction with others at Greenwich, would enable me to make corrections of latitudes of places given in our former papers, if found neceſſary. By fixing on Dunnoſe, I had alſo the means of aſcertaining the diſtance of the royal obſervatory from the northern or ſouthern end of my line, and, conſequently of connecting it with the parallels of Dunkirk and Paris."

For determining the amplitude of the arc, a zenith ſector was conſtructed by Ramſden. This was the laſt work of that great artiſt, and on which he had exerted all his talents to render it the firſt of its kind. The radius of the ſector was upwards of eight feet, and the object-glaſs of the teleſcope four inches in diameter.

The greateſt part of the ſummer of 1802 was employed by colonel Mudge in making obſervations with this inſtrument. It was firſt erected at Greenwich, afterwards at Dunnoſe, Clifton, and Arbury-hill; and ſo many ſtars were obſerved at each of theſe ſtations, that there can hardly remain a doubt of the relative latitudes being determined to the neareſt ſecond. It is true, we have met with ſeveral inſtances in the courſe of this hiſtory, of obſervations made with zenith ſectors, which agreed apparently very well with each other; and yet were affected by ſome common error of conſiderable magnitude, from ſome undue poſition of the plane of the inſtrument, either with reſpect to the vertical or the meridian; but colonel Mudge has ſufficiently ſhewn how improbable it is that ſuch ſhould be the caſe here, conſidering all the means that were employed, both by the artiſt and the obſerver, to avoid the poſſibility of ſuch an accident.

The obſervatories of Greenwich and Blenheim were transferred upon the arc by means of triangles, obſerved in the former ſurvey; and thus the latitudes of five different points on it were obtained. The directions of the meridian with the ſides of the triangles were obſerved both at Clifton and Dunnoſe, by obſervations of the pole-ſtar, at its greateſt elongation, eaſt and weſt from the meridian. This method, which has uniformly been adopted throughout the Engliſh ſurvey, is the moſt accurate that can be deviſed. For this kind of obſervation, the repeating circle is much inferior to the theodolite.

The extreme ſtations were connected by twenty-two triangles as follows. (Vid. *Plate* VIII. *fig.* 69.)

Calculation of the Meridional Distance between Dunnose and Clifton.

The bearings of certain sides from the parallels to the meridian of Dunnose, by observations of the pole-star at Dunnose.

	°	′	″	
Dunnose and Butser-hill -	20	58	39	N.E.
Butser-hill and Highclere -	34	20	17	N.E.
Highclere and Nuffield -	35	30	40	N.E.
Nuffield and Brill - -	4	51	15	N.W.
Brill and Arbury-hill -	12	30	17	N.W.
Arbury-hill and Bardon-hill	7	42	57	N.W.
Bardon-hill and Orpit -	21	21	9	N.W.
Orpit and Heatherfedge -	5	25	52	N.W.
Heatherfedge and Beacon-hill	61	52	17	N.E.

These bearings, and their respective sides, give the following distances on the meridian of Dunnose.

	Feet	Miles.
Dunnose and Butser-hill	131,263.0 =	24.86
Butser-hill and Highclere	122,232.7 =	23.15
Highclere and Nuffield	97,984.7 =	18.56
Nuffield and Brill -	91,755.3 =	17.38
Brill and Arbury-hill -	143,054.1 =	27.09
Arbury-hill and Bardon-hill	178,792.4 =	33.86
Bardon-hill and Orpit -	126.567.8 =	23.29
Orpit and Heatherfedge	101,203 7 =	19.17
Heatherfedge and Beacon-hill	43,480.7 =	8.23
	1,036,334 =	196.27,

the distance between Clifton and the perpendicular to the meridian of Dunnose, which may be taken for the true length of the arc itself, as the distance of the former station from the meridian of the latter is only 4770 feet.

Bearings of the ſame Sides, deduced from the Obſervations made at Clifton.

	°	′	″	
Beacon-hill and Heatherſedge	61	51	50	S.W.
Heatherſedge and Orpit -	5	26	19	S.E.
Orpit and Bardon-hill -	21	21	36	S.E.
Bardon-hill and Arbury-hill	7	43	26	S.E.
Arbury-hill and Brill -	12	31	0	S.E.
Brill and White-horſe-hill -	50	15	48	S.W.
White-horſe-hill and Highclere	27	48	6	S.E.
Highclere and Butſer-hill -	34	20	49	S.E.
Butſer-hill and Dunnoſe -	20	58	9	S.W.

Theſe bearings and ſides give the following párallels to the meridian of Clifton:

Beacon hill and Heatherſedge -	43,490.4
Heatherſedge and Orpit - -	101,202.6
Orpit and Bardon - - -	126,561.3
Bardon-hill and Arbury-hill - -	178,793.2
Arbury-hill and Brill - - -	143,047.4
Brill and White-horſe-hill - -	93,717.6
White-horſe-hill and Highclere -	96,031.4
Highclere and Butſer-hill - -	122,219.8
Butſer hill and Dunnoſe - -	131,270.2

The ſum 1,936,33.39 feet, is the diſtance between Dunnoſe and the perpendicular to the meridian of Clifton; or the length of the arc itſelf. There is therefore a difference of only half a foot between the two reſults. We may conſequently take 1,036,334 for the diſtance required.

The ſubtenſes in the heavens of the different parts of the terreſtrial arc are as follows:

	°	′	″
1. Dunnoſe and Clifton - -	2	50	23.38
2. Dunnoſe and Arbury-hill -	1	36	19.98
3. Arbury-hill and Clifton -	1	14	3.40
4. Dunnoſe and Greenwich -	0	51	31.39
5. Greenwich and Clifton -	1	58	51.59
6. Arbury-hill and Greenwich	0	44	48.19
7. Dunnoſe and Blenheim -	1	13	19.69
8. Blenheim and Clifton - -	1	37	3.69

The following terreſtrial arcs are thoſe uſed in conjunction with the preceding ones for computing the length of a degree:

Arcs	Feet.
1. Dunnoſe and Clifton - -	1,036,337
2. Dunnoſe and Arbury-hill -	586,320
3. Arbury-hill and Clifton - -	450.017
4. Dunnoſe and Greenwich -	313,696
5. Greenwich and Clifton - -	722,641
6. Arbury-hill and Greenwich -	272,624
7. Dunnoſe and Blenheim -	446.498
8. Blenheim and Clifton - -	589,839

And by ſimply dividing the terreſtrial arcs by their correſponding celeſtial ones, and afterwards multiplying the ſeveral quotients by 3600″, we ſhall get the length of the degrees as follows:

	Fathoms.
Middle point between Dunnoſe and Clifton	60,820
Dunnoſe and Arbury-hill	60,864
Arbury-hill and Clifton	60,766
Dunnoſe and Greenwich	60,884
Greenwich and Clifton	60,794
Arbury-hill and Greenwich	60,849
Middle point between Blenheim and Clifton	60,769
Blenheim and Dunnoſe	60,890

Taking the latitude of Greenwich at 51° 28′ 40″ from the ſeveral arcs now given, the latitudes of their middle points are eaſily found, and, with the lengths of the degrees, when properly arranged, will ſtand as follows:

	Lat. of middle Point.	Fath.
	° ′ ″	
Arbury-hill and Clifton -	52 50 29.8	60,766
Blenheim and Clifton - -	52 38 56.1	60,769
Greenwich and Clifton -	52 28 5.7	60,794
Dunnoſe and Clifton - -	52 2 19.8	60,820
Arbury-hill and Greenwich -	51 51 4.1	60,849
Dunnoſe and Arbury-hill -	51 35 18.2	60,864
Blenheim and Dunnoſe -	51 13 18.2	60,890
Dunnoſe and Greenwich -	51 2 54.2	60,884

Colonel Mudge thus concludes his account of this operation:

"From this meaſurement it appears, that the length of a degree on the meridian, in latitude 52° 2′ 20″, is 60,820 fathoms. This concluſion is deduced from the ſuppoſition of the whole arc ſubtending an angle of 2° 50′ 23″.38 in the heavens, and a diſtance of 1,036,337 feet on the ſurface of the earth.

"The length of the degree at the middle point (51° 35′ 18″) between the ſouthern extremity of the arc and Arbury-hill, is 60,864 fathoms; which is greater than the above, and exceeds it by 44 fathoms. But this degree, admitting the earth to be an ellipſoid, with the ratio of its axes as 229 to 230, ſhould be about 10 fathoms leſs. If the meaſurement of the terreſtrial arc be ſufficiently correct, and the earth of an elliptical form in theſe latitudes, either the arcs affording the deductions are incorrect, or ſome material deflection of the plumb-line has taken place, at one or two ſtations, from the effect of attraction.

"Without arrogating to myſelf any merit from the pains taken in the performance of this undertaking, I may ſay, I am ſo perfectly convinced of the general accuracy of the whole, that I cannot for a moment doubt the collective evidence of its ſufficiency. From an examination of my field books, and from the remeaſurement of the chains uſed in our baſe-line on Miſterton Carr, I think it is probable that an error in the whole diſtance, of 197 miles nearly, does not ſubſiſt to an amount of more than 100 feet, correſponding to 1″ in the amplitude of the whole arc, and I alſo think it probable it cannot amount to half that quantity. The ſuppoſition of the zenith diſtances of the ſtars being generally erroneous, at any one ſtation, cannot be admitted, unleſs it ſhould be imagined, that the plane of the ſector's limb was not got into that of the meridian. Such an idea, however, can ſcarcely be entertained, after a careful examination of the ſeveral obſervations, and a due attention to the means by which the inſtrument was made to aſſume its right poſition. Perhaps, alſo, I ſhould not fail to obſerve, in this place, that although the inſtrument was always brought into the plane of each meridian by means of the teleſcope attached to the ſide of the great tube, and the azimuth circle, yet, having two good chronometers in my poſſeſſion, I repeatedly verified the truth of the ſector's poſition, by obſerving the tranſits of two ſtars, north and ſouth of the zenith, at the greateſt diſtances my arc would admit of. But, to return, if there be an error in the amplitude of the total arc, from a deflection of the plumb-line at either of the ſtations,

tions, it is not probable that any ſuch deflection exiſted at Dunnoſe; as the deviation of it towards the north, from a deficiency of matter towards the channel, would tend to diminiſh the inequality between the lengths of the two degrees. This will be evident, on conſideration. I am therefore diſpoſed to believe that the plumb-line was drawn towards the ſouth, from the action of matter, both at the northern extremity of the arc and at Arbury-hill, but more particularly at the firſt-mentioned ſtation. If this were partly the caſe, and both Dunnoſe and Arbury-hill were free from any ſuch prevailing cauſe, the total arc muſt be too great, if taken at 2° 50′ 23″.38, by about 8″, nearly anſwering to 2″ on each degree. A deviation of 8″ from the true vertical is a large quantity; nor can the cauſe of it be aſſigned, unleſs it be alſo ſuppoſed, that the matter producing that deflection extends in a ſouthern direction *beyond* Arbury-hill. If the error, though not probable, as above obſerved, be ſuppoſed to exiſt at Dunnoſe, it muſt amount to more than 10″; and that too from the effects of attraction in a ſouthern direction, where the deficiency of matter would lead us to believe the reverſe would happen.

"I am perfectly aware that it is poſſible to ſtate a caſe, in which the plumb-line of a ſector would deviate from the true vertical by ſuch a quantity. Thus, for inſtance, in a chalky county, like the ſouthern part of the kingdom, if the inſtrument were ſet up adjoining the terminations of two ſtrata running eaſt and weſt, one of chalk, and the other of much denſer materials, the effect would be as we have found it. But, at Dunnoſe, this argument does not apply; nor is there reaſon to believe, from external appearances, that it will do ſo, with regard either to Arbury-hill, or the northern extremity of the meridional line.

"It was the diſcovery of the diſagreement between the ſubtenſe in the heavens, of the whole arc, and its correſponding terreſtrial one, with thoſe of its parts, which led me to apply to his grace the duke of Marlborough, for the obſervations made at Blenheim on γ Draconis, or ſome other ſtar. His lordſhip's compliance with my requeſt is ſhewn, from the table of the reſults, to be ſerviceable; as the arc contained between the obſervatory at Blenheim and Dunnoſe, deduced from his grace's obſervations, and thoſe made at the latter place, with the meridional diſtance 446,498 feet, give 60,890 fathoms, for the length of the degree on the meridian in latitude 51° 13″; which agrees nearly with the length of the degree at the middle point between Greenwich and Dunnoſe. However, under all conſiderations of the means by which the degree in 51° 13′ has been obtained, I am inclined to believe there is an uncertainty in it, of 6 or 7 fathoms, anſwering to about $\frac{1}{2}$″ in latitude.

"But, if the meaſured ſpace between his grace's obſervatory and Dunnoſe, with its amplitude, (1° 13′ 19″.69) be uſed in finding the meridional diſtance of the whole arc, (its correſponding amplitude,) we ſhall get 2° 50′ 11″.80 for its ſubtenſe; which argues a deflection from the vertical at Clifton = 11″.79. If the meridional diſtance between Dunnoſe and Greenwich be uſed, we ſhall, from the ſame mode of proceeding, make it = 10″.3. In ſhort, the general tenor of the obſervations ſeems to prove, that the plumb-line of the ſector has been drawn towards the ſouth at all the ſtations; and that by attractive forces, which increaſe as we proceed northward. On a further proſecution of this ſurvey, the zenith ſector will be taken forward in that direction, which will afford an opportunity of throwing further light on this intereſting ſubject. But meridional operations carried on in inſular countries, are not ſo likely to afford juſt concluſions with regard to the different lengths of the degrees, as the ſame operations conducted in places very remote from deep ſeas.

"From the late operations of the French academicians it appears, that the meridional diſtance between Dunkirk and Barcelona is 275.792.36 modules, the metre being 443.296 lines of the Peru toiſe = 0,256,537th part of the module, at the temperature of melting ice. This meridional diſtance, therefore, converted into Engliſh feet, is 3.527,921. The diſtance between Dunkirk and Paris is 133 758 feet, and the diſtance between Paris and Greenwich is = 963 954 feet; therefore, 830,196 feet is the diſtance between Greenwich and Dunkirk. The diſtance between Greenwich and Clifton is 722.641 feet; hence, 4,411.968 feet is the meridional diſtance between Clifton and Barcelona. The latitude of Barcelona is 41° 21′ 48″.8; the latitude of Greenwich is 51° 28′ 40″; and if to this latitude we add 1° 58′ 51″.59, the arc between Clifton and Greenwich, we ſhall get 53° 27′ 31″.59 for the latitude of Clifton: and ſhall then have the difference of latitude between Barcelona and Clifton = 12° 5′ 42″.79, ſomething more than the 30th part of the whole circumference of the earth. With this difference of latitude, and the above-mentioned diſtance, we ſhall get 60,795 fathoms, for the mean length of a degree on the earth's ſurface, in latitude 47° 24′. The latitude of Paris is 48° 50′ 15″; this, with that of Clifton, gives 4° 37′ 16″.59 for the difference between their parallels. The meridional diſtance is 1,686,595 feet; hence, 60,825 fathoms is the length of the degree in latitude 51° 9′."

Of the trigonometrical Operations in France, ſince 1790.

While this great work was carried on in England, a ſimilar one was undertaken in France, and on a larger ſcale, as the arc meaſured in that country began at Dunkirk, and extended beyond the frontiers to Barcelona in Spain. The immediate purpoſe of this operation was to obtain a ſtandard meaſure, which ſhould not be arbitrary, but founded on ſome permanent quantity afforded by nature. Many learned men were advocates for taking the length of the pendulum as a ſtandard; but after much deliberation, it was reſolved to adopt the ten millionth part of the quadrant of the meridian for the unit, which was to be called a metre, and from this all other meaſures were to be derived. See MEASURE.

To obtain this ſtandard it was requiſite to inſtitute a new ſeries of obſervations, to determine the magnitude and figure of the earth in a more ſatisfactory manner than had hitherto been done; and preparations were made for again repeating the whole proceſs for the meaſurement of an extenſive arc of the meridian.

The moſt remarkable difference in the mode of conducting the ſurveys in the two countries, was in the inſtruments employed for the meaſure of the angles. The only one uſed by the French aſtronomers was the repeating circle of Borda. We are fully inclined to give credit to all that is related of the extraordinary accuracy of this ingenious inſtrument; at the ſame time, we are diſpoſed to think the theodolite of Ramſden a preferable inſtrument for great national ſurveys, where circumſtances will permit its uſe. The ſuperiority of the theodolite conſiſts in its ſize, the great power of its teleſcope, and the facility with which all azimuthal angles are obſerved with it, without any correction; as it combines all the verifications of a tranſit inſtrument, the pole ſtar can be brought to the horizon without ſenſible error, and its azimuth ſerves to give the direction of the ſides of the triangles in a manner infinitely more exact than we believe can be done by any management of a repeating circle. On the other hand, the latter inſtrument ſupplies the place of a

zenith

zenith ſector; and from its being light and portable, admits of its being taken into ſituations inacceſſible to a larger inſtrument. Whoever peruſes the account of the French ſurvey, will at once perceive that ſo large an inſtrument as the theodolite of Ramſden would have been totally uſeleſs in that country. The repeating circle requires a great number of corrections, but theſe are rendered eaſy by the means of tables; and it muſt be obſerved, that many of the corrections uſed by the French aſtronomers do not depend on the nature of their inſtrument, but on its poſition, which was ſeldom or never that of the centre of the ſtation; the diſturbed ſtate of the country, and the want of ſufficient pecuniary aſſiſtance, prevented them from erecting ſignals at ſelect ſtations, as was practiſed in this country; on the contrary, they were obliged to ſelect ſuch ſteeples, towers, windmills, and other conſpicuous buildings as the country afforded, which were often very inconveniently diſpoſed for the reception of their inſtrument, ſmall and portable as it was.

The committee appointed by the ancient academy, conſiſting of Lagrange, Laplace, Monge, and Condorcet, publiſhed their report on this intended operation in the memoirs of the academy for 1788. It was propoſed, among a variety of other objects relative to the new meaſures, to meaſure an arc of the meridian from Dunkirk to Barcelona, exceeding $9^{\circ}\frac{1}{2}$. This arc had the advantage of being terminated at each extremity by the level of the ſea, and it was extended beyond the Pyrenées, that the influence of mountains on the plumb-line might be avoided.

Thoſe to whom the execution of this undertaking was committed were inſtructed to determine the latitude of Dunkirk and Barcelona, and other intermediate ſtations, to re-meaſure the ancient baſes, to verify again the former triangles, and to extend them to Barcelona. From the ſucceſsful trial that had been made of the repeating circle in 1787, it was again adopted, but of rather larger dimenſions; and four of them were conſtructed by Le Noir, from 14 to 18 inches diameter, to be employed in this occaſion. The execution of the whole was entruſted to Mechain and Delambre. The former undertook the ſouthern part, from Rodez to Barcelona; the latter the northern, from Rodez to Dunkirk.

One of the laſt acts of the unfortunate Louis XVI. was a proclamation to place theſe aſtronomers and their ſignals, inſtruments, &c. under the ſpecial protection of the adminiſtrative authorities; but the paſſports of this expiring government only rendered them objects of greater ſuſpicion, and increaſed their difficulties and dangers.

Mechain, after encountering ſeveral vexatious interruptions in the vicinity of Paris, at length was fortunate enough to arrive within the Spaniſh frontiers, where, in the neighbourhood of Barcelona, he completed ſeveral triangles; and, by the end of October 1792, had terminated the angles at fort Montjouy, the ſouthern extremity of the arc: here he reſolved to wait during the winter, and devote it to obſervations for determining the latitude and azimuth of this ſtation.

Delambre began his obſervations in the neighbourhood of Paris, in the ſummer of the year 1792, and on the memorable 10th Auguſt, ignorant of what was paſſing at Paris, he went after dark to his ſtation; but inſtead of ſeeing the ſignal lamp lighted on Montmartre for his obſervation, as had been previouſly agreed, he beheld the flames from the palace of the Thuilleries. It was in the dreadful period of alarm and diſmay which followed, that this indefatigable aſtronomer began to obſerve the ſeries of triangles to the north of Paris: at almoſt every village he was arreſted, and obliged to explain to the populace the uſe of his inſtruments and the nature of his miſſion; and in more than one inſtance, where this lecture did not ſuit the taſte of the mob, he very narrowly eſcaped deſtruction. It ſeems to have been deſtined that the great undertakings of the French, relative to the meaſurement of the earth, ſhould be accompliſhed under circumſtances peculiarly unpropitious. But the inclement froſts of the arctic circle, and the hurricanes of the Andes, which ſo much diſtreſſed their former aſtronomers, ſeem to have been mild and benignant agents of nature, when compared to the violence of a ferocious and exaſperated mob.

Yet, amidſt all theſe ſtorms, with a coolneſs and intrepidity truly admirable, had Delambre ſucceeded in completing a great number of triangles, when he was removed from his ſituation by a decree of the committee. This decree, after ſetting forth the importance to the amelioration of public opinion, *eſprit public*, that perſons concerned in theſe operations ſhould be diſtinguiſhed by their republican virtues, and hatred to kings, ordains that Borda, Lavoiſier, Laplace, Coulomb, Briſſon, and Delambre, ſhould ceaſe to belong to the commiſſion. This order is ſigned Barrere, Robeſpierre, Billaud-Varenne, Couthon, Collot d'Herbois, &c.

Mechain for a long time had not been heard of, and to this circumſtance he was indebted for not being included in the proſcribed liſt, as it was feared he might take refuge with his inſtruments in Spain. It is ſaid that very advantageous offers were made him to this effect, which, after the ſuppreſſion of the academies in France, he might without any great impropriety have liſtened to; but he was too much attached to the great work in which he was engaged to be influenced by any other views that were not directed to its accompliſhment. Notwithſtanding the war between the two countries, he continued his obſervations, but not without frequent interruptions; and before he had concluded his triangles, he was detained as a priſoner by the Spaniſh government, but permitted to chooſe his reſidence, which he fixed at Barcelona, that he might be as near as poſſible to the fort of Montjouy, which was the extreme ſtation of the arc, and whoſe latitude he had previouſly determined. Being denied acceſs to the fort, he employed himſelf in determining the obliquity of the ecliptic, by ſolſtitial altitudes of the ſun, taken with the repeating circle, and connected his obſervatory with the fort trigonometrically, an inſtructive example of the triumph of ſcience over ſuſpicious ignorance. The Spaniards probably thought that the determination of the latitude and longitude of a fort was a preliminary ſtep to the capture of it. Mechain continued here reduced to a very diſtreſſed condition; what remained of his finances was confiſcated as French property. After a conſiderable time, he at laſt was ſuffered to embark for Genoa.

After the death of Robeſpierre, and under the government of the executive directory, they were again, after an interruption of eighteen months, permitted to reſume their labours. This recommencement did not take place, however, under very auſpicious circumſtances; Delambre was once detained a month at a town for want of money to defray his expences, as he was only furniſhed with aſſignats, which were ſo much depreciated, that in ſome places nobody would take them at any diſcount. With theſe and a thouſand other difficulties, they ſucceſsfully ſtruggled and accompliſhed the taſk committed to them, with a preciſion, which, if it had been executed under every favourable circumſtance, would have deſerved our utmoſt admiration. Mechain carried his ſeries of triangles over the moſt inhoſpitable receſſes of the Pyrenées, till he finally united them with thoſe of Delambre in the ſouth of France.

He returned to Spain, and was arduouſly engaged in continuing

tinuing the meridian to the Balearic iſles, in the Mediterranean, when, overcame and exhauſted by the extreme fatigue he had endured, this excellent aſtronomer expired at Caſtellon de la Plana, in the kingdom of Valencia, in the autumn of the year 1805.

The baſe originally choſen by Picard, and ſo often remeaſured, was now abandoned, as ſeveral of the neighbouring ſteeples and ſignals had gone to decay. Two new baſes were choſen; one between Melun and Lieurſaint, the other near Perpignan. The firſt meaſured 6075.90 toiſes, the latter 6006.247 toiſes. They were meaſured with rods of platina, their ends being placed near each other, and the diſtance meaſured by a micrometer; inſtead of applying thermometers to the rods, a braſs ſcale with a vernier was affixed to each rod, ſo as to ſhew its relative ſtate of expanſion when compared to braſs during the operation. When the length of one of theſe baſes was inferred by computation from the other, it did not differ 12 inches from the meaſurement, though the diſtance between them was between four and five hundred miles.

The latitudes of three intermediate points were obtained in the courſe of the ſurvey, beſides the latitudes of Dunkirk and Montjouy. Theſe with the contained arcs expreſſed in modules were as follows:

					Modules.	Metres.
Dunkirk	51°	2′	10″			
				DP	62472.59	=243522.1
Pantheon, Paris	48	50	49.7			
				PE	76145.74	=296821.9
Evaux -	46	10	42			
				EC	84424.53	=329093.2
Carcaſſone	43	12	54			
				CM	52749.48	=205621.3
Montjouy	41	21	45			

Total Arc = 1075058.5

The degrees derived from theſe intermediate obſervations on different parts of the arc, varied almoſt as much as in the Engliſh ſurvey, and in a manner equally irregular, and contrary to every received hypotheſis of the earth's figure. The decreaſe of the degrees towards the northern extremity was at firſt very ſlow; beyond Evaux they decreaſed very rapidly; and beyond Carcaſſone they again diminiſhed more ſlowly. The ellipticity deduced from the meaſures in France, independent of thoſe obtained in other countries, is $\frac{1}{156}$, the ſame that was deduced from the meridional and perpendicular degree in the ſouth of England. As this reſult was ſuppoſed to intereſt equally all civilized nations, a commiſſion was appointed, conſiſting of the members of the Inſtitute, and a number of learned and ſcientific men from different parts of Europe. Before this commiſſion all the papers and documents of the reſpective obſervers were laid, with an account of the meaſurement of the baſes, and of all the corrections and computations that had been applied. The commiſſioners themſelves drew up the table of triangles, from which the arc of the meridian was ultimately to be computed.

The triangles are given by the French aſtronomers in a form ſomewhat different from thoſe in the Engliſh ſurvey. By referring to theſe it will be ſeen that general Roy, when he firſt took notice of the ſpherical exceſs of three angles above two right angles, applied the correction ariſing from it, in rather an incorrect manner (as will be fully explained hereafter). Colonel Mudge reduces his angles to chord lines, which method is likewiſe adopted by Delambre. But as there are three different ways in which a triangle on the ſurface of the earth may be computed, the French have given their triangles in three different forms, ſuited to the three modes of computation, which ſhould all give the ſame reſult, as they are all three rigorouſly exact, at leaſt in triangles of ſmall extent compared with the whole earth.

It would occupy more ſpace than we could allow to inſert the whole chain of triangles from Barcelona to Dunkirk, but we ſhall annex the 36 triangles which connect Paris and Dunkirk, which will complete the ſeries from Greenwich to Paris, and at the ſame time afford the mathematical reader a valuable ſpecimen of the moſt accurate methods of preparing theſe triangles for computation.

The final deduction that was obtained from this laborious inveſtigation, was as follows.

Ellipticity or compreſſion -		$\frac{1}{334}$.
Longer ſemi-axis of the earth		3271226 toiſes,
	or	6375737 metres,
		20918830 Engliſh feet.
Shorter ſemi-axis - -		3261432 toiſes,
		6356649 metres,
		20855922 Engliſh feet.

The quadrant of the meridian contained 5130740 toiſes, conſequently the metre was equal to 443,295,986 lines.

Table of thirty-ſix Triangles, which connect the Tower of Dunkirk with the Pantheon at Paris.

The firſt two columns of this table require no explanation.

The third contains the obſerved angles, ſuch as were decided by the commiſſion appointed to examine the obſervations.

The fourth contains, under the title ſpherical exceſs, the difference between the ſpherical angle of the arcs, and the rectilinear angle of the chords.

The fifth contains the ſpherical angles corrected for computation.

The ſixth contains the ſpherical angles diminiſhed by their ſpherical exceſs, and are the rectilinear angles formed by the chords.

The laſt column contains the mean angles or the ſpherical angles corrected each by one-third of the ſpherical exceſs: in this ſtate they may be calculated by the rules of plane trigonometry, as appears by a very curious theorem of Legendre. All theſe methods will be fully illuſtrated before we conclude this ſubject.

Meaſure of a Degree in Sweden.

Mr. Swanberg's account of the trigonometrical operations in Lapland, for the purpoſe of determining the value of an arc of the meridian, is a work that would at any time have excited conſiderable attention from the importance of its object, and the correctneſs of the operations it details. But at preſent it derives additional intereſt from the difference between this degree, and that formerly meaſured in the ſame country by Maupertuis, Clairault, &c. and from its agreement with that which reſults from the late operations carried on in France and Spain.

The ſummer of the year 1801 was entirely employed by the Swediſh aſtronomers in the choice of ſtations, and the conſtruction of ſignals. They then returned to Stockholm, to await the arrival of the circle conſtructed for them by M. Lenoir, and the ſtandards of the double metre, and of the toiſe employed in Peru, which the members of the Inſtitute ſent to the academy at Stockholm.

The meaſure of the baſe was begun February the 22d, at Niemiſby, and finiſhed April 11th at Poiki Tornea. They were then obliged to wait for the ſummer to meaſure the angles. June, July, and Auguſt were employed in theſe operations. Mallorn is the moſt ſouthern, and Pahtavara the moſt northern point of theſe triangles, which amount to 31 in number, including ſome ſubſidiary triangles of verification. The new arc is 1° 37′ 19″.56, that of 1736 was 57′ 27″ or 30″: the difference is about 39′ 40″.

The Swediſh aſtronomers, in that part of the arc which coincided with the French, have employed the ſame ſtations for their ſignals, except the Finland church at Tornea, which they have ſubſtituted for the church of the town. The ſouthern points of the chain of triangles are in the iſlands of the gulf of Bothnia, and diverge but little from the meridian of Kittis, to which the French aſtronomers reduced all the ſides of their heptagon.

They commenced the aſtronomical obſervations the 7th of September, at Mallorn, by obſerving the zenith diſtance of the pole-ſtar. But they did not conſider theſe obſervations as correct, from ſome irregularity in the rate of the clock. Thoſe to be relied on do not commence till October the 5th, and terminated the 24th. The obſervations of the pole-ſtar at Pahtavara commenced the 10th of December, and continued the 11th, 18th, 23d, 24th, and 25th; on the 26th and 27th they obſerved the ſame ſtar below the pole, which they had not been able to do at Mallorn. The azimuthal obſervations were made at both extremities of the arc; but M. Swanberg has only calculated thoſe of Mallorn, becauſe at Pahtavara he had not aſcertained the rate of his clock accurately enough for a calculation, in which the hour angle is ſo important an element. He thought the obſervations at Mallorn more than ſufficient, conſidering the ſlight effect a ſmall error in the azimuth could produce on an arc of the meridian.

The baſe was meaſured with iron rods, or bars, rather more than ſix metres in length, covered at each extremity with two plates of ſilver, to prevent the effect which moiſture might have on the iron. Two lines were drawn on theſe plates, the interval between which was exactly ſix metres. The ends of theſe rods were placed ſide by ſide, during the meaſurement, ſo that theſe lines preciſely coincided. This meaſurement being performed in the middle of winter, they found the atmoſphere ſo much obſcured by continual fogs, that they could not from one end of the baſe ſee the ſignal placed at the other. This compelled them to trace the baſe by means of intermediate pickets. M. Swanberg computes the errors that might poſſibly ariſe from this method, and ſuppoſes the baſe to be a polygon inſcribed in a logarithmic ſpiral; the correction appears to be too ſmall a quantity to deſerve notice.

The planks which ſupported the iron rods being elevated half a metre from the ſurface of the ground, they made uſe of a braſs pendulum furniſhed with a level, to aſcertain the ſpot, where they left off, that they might recommence from the ſame place, as the winds which blew continually would have rendered a plumb-line of little or no uſe. When they quitted their labours in an evening to return home, they firſt made a heap of ſnow, which they rendered as compact as poſſible by preſſure; and on this placed a deal tablet, which was ſurrounded with ſnow to render it immoveable, and on which they marked the point where they quitted their operation. The bulb of the thermometer, which indicated the temperature of the rods, was in contact with the iron, and it was by no means an extraordinary phenomenon for the mercury to deſcend 30° below the freezing point.

M. Swanberg imagines that he began his baſe very nearly at the ſame ſpot with the French academicians. But it is the opinion of M. Delambre (who is in poſſeſſion of a work by M. Outhier, containing particulars that M. Swanberg was unacquainted with), that the new baſe is four feet ſhorter at this end than the old one. There is no rock at the northern extremity, and their reſearches to find ſome veſtiges of the old termination were totally uſeleſs; as M. Maupertuis has left no indication of this ſpot.

The abbé Outhier ſays, that the French baſe terminated in a ſignal at the northern extremity; and that the marks were croſſes, but made on the bark of four fir trees, two on each tree, one at the height of a man, the other near the ground. Theſe trees formed a quadrilateral figure, the interſection of the diagonals of which was the centre of the ſignal. It is poſſible that theſe trees might no longer exiſt: but one of them was remarkably ſituated; it ſtood near the bank of the river, and touched the incloſure of a field.

Now M. Swanberg's baſe terminated in a field, which he believes to be the ſame. It was divided between the peaſants of the villages of Sarkivara and Rahtola; and as there was no rock or ſtone on which he could mark his boundary, he ſtopped at the incloſure which ſeparated the poſſeſſions of theſe two villages, concluding that intereſt would induce them to repair this boundary, whenever it was injured. To preſerve the preciſe point at which the baſe terminated, he had a pit dug about a metre and a half in depth immediately below the incloſure. They then charred the ſurface of a thick trunk of a fir tree, to render it leſs liable to decay, and placed it in the pit, ſurrounded with gravel and pebbles, to render it immoveable. Its centre was pierced with a thick braſs wire, and it was covered with iron plates, on which a croſs was engraved, the centre of which correſponded to that of the trunk.

M. Delambre thinks, that if this incloſure was the ſame with that deſcribed by the abbé Outhier, the new baſe would be 10 or 12 toiſes ſhorter than that of 1736, ſuppoſing 11 toiſes, adding the 4 toiſes at the other end, we ſhould have about 12 toiſes, that the new baſe would be ſhorter than the old one. But M. Swanberg's is 7414.5 toiſes, the other only 7406.8 toiſes, which is, on the contrary, leſs by 8 toiſes.

M. Delambre ſuſpects that the new baſe was not ſo oblique to the river as the other; and concludes, after a very careful examination of the queſtion, that neither of the extremities of M. Swanberg's baſe coincided with that of M. Maupertuis. And it is his opinion that the difference between the degree of 1802 and that of 1736, does not ariſe from any error in the trigonometrical operations, but depends wholly

wholly on an error in the amplitude of the arc which he eſtimates at 10″ or 12″.

Theſe are the ſides common to both the operations.

		Swanberg.	Outhier.

The obſervations which were made to determine the latitude of the extreme ſtations gave likewiſe, with the greateſt accuracy, the declination or polar diſtance of the pole-ſtar. Mr. Swanberg deduces it from his obſervations 1° 45′ 36″.2, for the beginning of year 1800; Delambre and Mechain, from the mean of ſome hundred obſervations, 1° 45′ 35″.4; by Mr. Pond's tables in Philoſophical Tranſactions inſerted under DECLINATION, it is 1° 45′ 36″; perhaps the poſition of no ſtar was ever ſo well known. The reſult of Mr. Swanberg's meaſurement and calculation is as follows.

The length of the baſe reduced to the level of the ſea, at the temperature of zero, was 7414.4919 toiſes, or 14,451.116 metres. The diſtance between the parallels of Pahtavara and Mallorn 92,767.981 toiſes or 180,827.68 metres.

The latitude of the centre of the ſignal at Mallorn was 65° 31′ 30″.26, and at Pahtavara 67° 8′ 49″.83. Therefore the latitude of the middle point was 66° 20′ 10″.04; the amplitude of the whole arc 1° 39′ 19″.56; and the value of the degree 57,196.159 toiſes. The moſt probable ellipticity deduced from comparing theſe determinations with thoſe made in Peru, the Eaſt Indies and France, is $\frac{1}{323.065}$, and the radius of the equator 3371452 toiſes.

The degree of Maupertuis exceeds that of Mr. Swanberg 224 toiſes. If the error had been the other way, and if at the ſame time the aſtronomers at Peru had committed an equal error in their determination, the polar axis would have appeared the longeſt.

The account which Mr. Swanberg has publiſhed of this operation is enriched with a number of valuable inveſtigations of various formulæ, for the computation and correction of ſpheroidical triangles, and of the different parts of a meridian line.—It is entitled "Expoſition des Operations faites en Laponie, pour la Determination d'un Arc du Meridien, en 1801, 1802, & 1803, par Meſſieurs Ofverbom, Swanberg, Holmquiſt, et Palander. Redigée par M. Swanberg."

The mathematical claſs of the national inſtitute, as a mark of reſpect to M. Swanberg, for the ſkill and analytical knowledge diſplayed in the above work, voted him the medal founded by M. De la Lande. *v.* Con. des Temps 1808, from which this account was chiefly taken.

Meaſurement of a meridional and perpendicular Arc in India.

In the Aſiatic reſearches, (vol. viii.) major Lambton has given a very circumſtantial account of the meaſurement of an arc of the meridian on the coaſt of Coromandel, in the latitude 12° 30′. This operation formed part of an extenſive ſurvey, which is intended to be carried acroſs the peninſula of India. It appears to have been conducted in a very intelligent and careful manner. The method the author has followed ſo exactly reſembles that of general Roy, and colonel Mudge, that it requires but little deſcription. The baſe was meaſured with a ſteel chain, made by Ramſden, and its rate of expanſion aſcertained by pyrometrical experiments.

It commenced at St. Thomas's mount, near fort St. George, and extended 40006.44 feet, in a direction nearly ſouth.

The angles were meaſured by a theodolite extremely ſimilar to that uſed in the Engliſh ſurvey; it was conſtructed by Mr. Cary, an artiſt who was brought up under Ramſden, and nothing inferior to him in the beauty and delicacy of his workmanſhip.

The triangles which connected the extreme ſtations were 32 in number; the obſervations of their angles ſeem to have been taken with great accuracy. The joint errors of the three angles in three inſtances amount to 5″; in general they are under 2″, ſo that the error of a ſingle angle never probably exceeded 2″, and was often within that quantity. The ſouthern extremity of the arc was at Trivandiporum, in lat. 11° 44′ 52″.6, near Pondicherry; the northern at Paudree, lat. 13° 19′ 49″.2.

The obſervations made to determine the amplitude of the arc were made with a zenith ſector, conſtructed by Ramſden. They conſiſt of zenith diſtances of Aldebaran, taken at each extremity. The coincidence of the obſervations that are publiſhed is ſatisfactory enough; but as ſome conſiderable previous diſagreement is alluded to, and as it is poſſible for a ſector to give obſervations which accord very well with each other, but affected with ſome common error, if there is any part of the proceſs on which we ſhould heſitate to place implicit reliance, it is this; but in making this remark we are very far from imputing the ſmalleſt inattention to the ingenious officer, who has conducted the whole of this operation in a manner that reflects great honour on himſelf and his profeſſion.

The direction of the meridian was determined by obſervations of the pole ſtar at its greateſt elongation, as practiſed ſo ſucceſsfully by general Roy; this method was likewiſe uſed to obtain the azimuthal angles for computing the value of a perpendicular degree. Theſe were taken at Carangooly hill, and Curnatighur, two ſtations nearly eaſt and weſt of each other, and diſtant about fifty-five miles.

In that part of the computation where it was neceſſary to aſſume ſome hypotheſis of the earth's figure, the author takes the ſpheroid reſulting from the meridional and perpendicular degree meaſured in England. This ſeems to have been injudicious; it would have been more ſtrictly correct to have taken, for a ſecond approximation, the ſpheroid derived from his own obſervations; but as he himſelf obſerves, the error ariſing from an erroneous ſuppoſition would be very ſmall. The final reſult which major Lambton obtains is, that the length of the meridional degree in latitude 12° 32′ is 60,495 fathoms, and perpendicular degree 61,061 fathoms.

We have now brought the hiſtorical part of our ſubject to a concluſion, and have enumerated every operation inſtituted for the meaſurement of the earth that is found upon record, from the earlieſt ages to the preſent day.

It is evident that the late attempts to inveſtigate the exact figure of the earth by actual meaſurement have not been attended with the ſucceſs that might be expected, when we conſider the exquiſite conſtruction of the inſtruments that have been contrived for this purpoſe, the intelligence that has

has been evinced in the uſe of them, and the ſcrupulous accuracy with which the obſervations have been computed. But notwithſtanding the ſanguine hopes that were entertained of removing every doubt on this queſtion, have been greatly diſappointed, yet the information we have obtained by theſe operations is by no means inconſiderable. The remaining uncertainty is now reſtricted within very narrow limits, and we may conclude with confidence that the errors of obſervation are no longer concerned in the anomalies that yet remain to be explained. Two cauſes are ſuggeſted as moſt likely to produce the diſcordance: either a great irregularity in the actual figure of the earth, or an extremely variable denſity of the materials that lie beneath its ſurface. Both theſe cauſes are probably concerned, but what preciſe ſhare is to be attributed to each, future obſervations alone can determine.

This ſubject will be again reſumed under *figure of the* EARTH, to which the reader is referred for an account of the other methods that have been employed in the ſolution of this problem.

The great improvements that have been made in the conſtruction of inſtruments deſigned for operations of this nature, have been the means of creating almoſt a new ſcience.

To derive all poſſible advantage from obſervations of ſuch extreme preciſion, it was requiſite to deviſe new formulæ, new modes of calculating the triangles, and many new corrections that were either imperfectly applied, or totally neglected by former obſervers. For theſe valuable additions to the ſcience of practical geometry, we are indebted to ſome of the firſt mathematicians of the age. They are to be found diſperſed in the tranſactions and memoirs of different learned ſocieties, and in the accounts of the ſurveys above enumerated.

Profeſſor Playfair has given a complete inveſtigation of the formulæ requiſite for calculating the different parts of a meridian line, and other circles on a ſpheroid. (See Edin. Phil. Tranſ. vol. v.) In the Engliſh ſurvey, a method entirely new, of calculating ſpheroidical triangles, is given by Mr. Dalby, and the account of this whole work begun by general Roy, and continued by colonel Mudge, is in itſelf a moſt complete treatiſe on the ſcience of trigonometrical ſurveying. The French method of obſervation neceſſarily required corrections of a more intricate nature than ours. And Delambre, with the account he has publiſhed of his own obſervations, has given a great number of practical rules, which, though derived from the moſt profound analyſis, he has reduced to ſuch a convenient form, that they may be employed by perſons who have acquired only a moderate ſhare of mathematical knowledge. La Place and Legendre have likewiſe both eſſentially contributed to the improvement of this ſcience.

We have hitherto entered but little into the mathematical part of this ſubject, not becauſe it was thought foreign to the plan of this work, but that the narrative might be given in as uninterrupted a form as poſſible. But as we are deſirous that nothing ſhould be omitted that relates either to the theory and practice of aſtronomy, or the ſciences connected with it, we propoſe to ſubjoin, by way of appendix to this article, a ſhort treatiſe on that part of geodetical trigonometry, that is more immediately applicable to the meaſurement of degrees, and other queſtions connected with the figure of the earth.

For the other methods of determining the figure of the earth, ſee PENDULUM, PARALLAX, &c.

On the Method of obſerving and correcting the Angles.

The angles may be obſerved either with a theodolite, or, what is nearly the ſame, a portable aſtronomical circle, or with the repeating circle of Borda.

A circular inſtrument, with two microſcopes to its azimuth circle, will give two meaſures of the angle required without changing the poſition of the whole inſtrument; namely, one by each microſcope, but with three verniers we obtain ſix meaſures of the ſame angle. Three verniers are therefore better than two microſcopes.

If this inſtrument be placed in the centre of the ſtation, no corrections will be required, except ſuch as relate to the ſpherical exceſs, or reduction to the chord, according to the mode of computation adopted, as will be explained hereafter; but if the inſtrument be placed out of the centre of the ſtation, a correction muſt be applied, as will be explained in the directions for the management of the repeating circle.

If the angles are taken with the repeating circle, ſeveral corrections will be required, ſome depending on the mechanical conſtruction of the inſtrument, and others on its poſition: the nature and method of application of theſe we ſhall endeavour to explain.

Under CIRCLE and DECLINATION, a full account has already been given of the mechanical conſtruction of this inſtrument, of the requiſite verifications, and mode of uſing it for aſtronomical purpoſes. It now only remains to deſcribe the method of employing it for geodetical obſervations.

The method of obſerving an angle between two objects with the repeating circle is as follows:

Firſt, bring the plane of the circle into the plane of the angle to be obſerved; if this is rightly performed, the interſection of the wires of the micrometer of the moveable teleſcope ſhould paſs over each object in its revolution round its centre. To effect this readily requires a little dexterity and practice. The plane of the inſtrument, when vertical, ſhould firſt be placed in a poſition nearly between the two objects, then inclined with the hand till the two objects ſeem to the eye equally diſtant from the plane of the circle. The inſtrument is then to be turned round its vertical axis, till one object is brought into the front, or upper teleſcope fixed at zero. The back or lower teleſcope ſhould be brought to the other. Then by the joint action of the feet ſcrews, and a ſmall motion, if requiſite, in azimuth, the two objects may be biſected by each of the micrometers. The upper teleſcope being brought, as above, to the left, and the lower to the right hand object, the firſt part of the operation will be accompliſhed. Then, without altering the relative poſition of the teleſcopes, the circle is to be turned towards the left by its general motion, till the under teleſcope is directed to the left hand object; the upper teleſcope is then to be releaſed, and turned round on the inſtrument, till it is directed to the right hand object. When each ſignal is accurately biſected at the ſame time, one obſervation is complete, and the verniers will ſhew the double of the meaſured angle. This is to be repeated till a ſufficient degree of certainty is obtained.

We ſhall give an example of an angle meaſured by an 18 inch circle, conſtructed by Mr. Troughton.

No. of Obſ.	Angle given by Inſt.	Angle deduced.

Correction

Correction for the Eccentricity of the lower Telescope.

When we begin the observation of an angle A C B, (*Pl.* VII. *fig.* 58.) the upper telescope is directed to the object A, to the left, in the direction C A. If the lower telescope was concentric, we should direct it towards C B, and the intercepted arc would give upon the limb the measure required. But, on account of the eccentricity, C D, the lower telescope, which is fixed in D, takes the direction D B. Afterwards, when we direct the lower telescope to A, the point D, by the movement of the instrument on its pivot, is transported to E, and the lower telescope takes the direction A E; so that the motion given to the instrument is equal to the ∠ D C F, and not to the ∠ A C B.

Now $DGE = ACE - ACD = ACE - BCD - BCA = ACE - BCD + BCA = (90° - A) - (90° - B) + BCA = 90° - A - 90 + B + BCA = BCA + B - A = BCA + \frac{CD}{CB} - \frac{CE}{CA}$; for the ∠'s A and B being very small, we may use the sines instead of the arcs. The upper telescope is thus turned to the left out of the ∠ A C B, a quantity $= BCA + \frac{CD}{CB} - \frac{CE}{CA}$; then, to bring it back to B, it must describe $ACB + \frac{CD}{CB} - \frac{CE}{CA} + ACB = 2ACB + \frac{CD}{CB} - \frac{CE}{CA}$; then, taking half the arc measured on the limb, we find $ACB + \frac{CD}{2CB} - \frac{CE}{2CA} = \frac{1}{2}$ (arc measured); then $ACB = \frac{1}{2}$ (arc measured) $+ \frac{CE}{2CA} - \frac{CD}{2CB}$. To find A C B, we must add $\frac{\frac{1}{2}\text{ eccentricity}}{G} - \frac{\frac{1}{2}\text{ eccentricity}}{D}$: D is the distance C B, from the object B, which is to the right, and G, the distance *e* A, from the object A, which is towards the left. In the figure, the eccentricity is to the left; if it had been to the right, it would have been negative, and the correction would have had contrary signs. The correction is always $= \frac{1}{2}$ the eccentricity, reduced to seconds, and divided by the distance of the object on the same side with the eccentricity, minus the $\frac{1}{2}$ eccentricity, divided by the distance from the other side, relatively to the eccentric telescope.

In circles constructed in this country by Mr. Troughton, the eccentricity of the lower telescope is one inch and four tenths, and $\frac{1.4\text{ inches}}{1\text{ fathom}} = \frac{1}{103}$: this quantity, reduced to seconds, will be $2002''.5 = \frac{206264.8}{103} = \frac{R''}{103}$; therefore, the correction will be $\frac{2002''.5}{G} - \frac{2002''.5}{D}$. The following table, which is calculated for the above-mentioned eccentricity, is of very easy application.

With the distance of the object, which is on the same side with the eccentric telescope, that is, the distance of the left-hand object in our instruments, enter the table, and take a correction, to which you will prefix the sign +. With the distance of the right-hand object, take a second correction, which is to have the sign —.

Example. Suppose the distance of the left-hand object to be 5000 fathoms, and the right-hand object to be distant 22,000 fathoms, and the eccentricity to the left, the distance of the object to the left = 5000 fathoms gives - - - + 0.40

Right 22,000 fathoms	-	— 0.09
Total correction	-	+ 0.31

If the two distances are equal, the terms destroy each other, and the correction becomes = 0.

The annexed table is calculated for an 18-inch circle of Mr. Troughton's construction.

He places his divisions from right to left; the observations, therefore, begins with the left-hand object.

Fathoms.	
1000	2″.00
2000	1.00
3000	0.67
4000	0.50
5000	0.40
6000	0.33
7000	0.30
8000	0.25
9000	0.22
10,000	0.20
11,000	0.18
12,000	0.16
13,000	0.14
14,000	0.13
15,000	0.13
16,000	0.12
17,000	0.12
18,000	0.11
19,000	0.10
20,000	0.10
21,000	.10
22,000	.09
23,000	.09
24,000	.08
25,000	0.08

It is a curious circumstance, first noticed by Legendre, that this correction for eccentricity, when applied to the three angles in a triangle, becomes zero.

For, if *a*, *b*, *e*, represent the sides of a triangle, we have the correction for the angle.

$$A = \frac{\frac{1}{2}e}{C} - \frac{\frac{1}{2}e}{b}$$

$$B = \frac{\frac{1}{2}e}{a} - \frac{\frac{1}{2}e}{c}$$

$$C = \frac{\frac{1}{2}e}{b} - \frac{\frac{1}{2}e}{a},$$

which together = 0.

Reduction of the observed Angle to the Horizon.

The repeating circle does not give directly the horizontal angle between two signals, but the oblique angle; it is necessary, therefore, to take the zenith distances of the observed objects, and then calculate the azimuthal angle by the resolution of a spherical triangle.

The reduction is as follows:

Let A = angle of position, or observed angle.
H = altitude of signal A.
b = altitude of signal B.

Let

Let $n = \text{fin.}^2 \frac{1}{2}(H + h)\ \text{tang.}\ \frac{1}{2}A - \text{fin.}^2 \frac{1}{2}(H - h)\ \text{cot.}\ \frac{1}{2}A$.

Then the cor. $x = n$, ſec. H, ſec. h.

If the zen. diſtances differ more than 2° or 3° from 90°, this formula may be employed.

$$\text{Sin.}\ \tfrac{1}{2}x = \sqrt{\frac{\text{fin.}\left(\frac{C+\delta+\delta'}{2}-\delta\right)\text{fin.}\left(\frac{C+\delta+\delta'}{2}-\delta'\right)}{\text{fin.}\ \delta - \text{fin.}\ \delta'}}$$

x being the angle reduced to the horizon, C the angle at the centre, δ and δ' the zen. diſtances of the ſignals.

To facilitate this reduction, we have added the tables calculated for this purpoſe by M. Delambre. By theſe tables we may at the ſame time reduce the horizontal angle to that formed by the chords.

The uſe of theſe tables will be eaſily underſtood by an example.

$H + h$ is the ſum of the zenith diſtances of the obſerved objects diminiſhed by 180°.

If the ſum ſhould be leſs than 180°, $H + h$ is the remainder required to complete 180°.

$H - h$ is always the difference between the two zenith diſtance.

$(H + h)$ and $(H - h)$ are always conſidered as poſitive numbers.

P + Q is the ſum of the diſtances in French toiſes between the obſerver and each of the ſignals.

P − Q is the difference between theſe diſtances; (P − Q) is always poſitive.

With (P + Q) and (P − Q) take in Tab. II., two numbers, to which you always muſt annex the ſign.

With the obſerved angle, take in Tab. IV. the number, *Tangent*, to which the ſign + muſt be always annexed, and which muſt be placed under the factor found by $H + h$.

With the ſame angle take in the adjoining column, *Cotangent*, to which annex ſign −, and place it under the factor found by $H - h$. Place theſe ſame numbers under the factors (P + Q) and (P − Q), as in the example. Make the four requiſite muliplications.

The difference of the two firſt products is the reduction to the horizon, to be applied according to its ſign.

The difference of the two laſt products is the reduction to the chords, to be applied with its proper ſign to the horizontal angle.

This laſt reduction is almoſt always ſubtractive, but it ſometimes becomes additive, by the fourth product exceeding the third.

In general, the fourth product is nothing, and the third always very ſmall; ſo that in calculating the reduction, which is indiſpenſable, it is very little more trouble to reduce the angle to the chords. Theſe tables are, in general, quite ſufficient for the reduction to the horizon; but, for greater exactneſs, Table III. is added. The difference of the products, as obtained above, may, by means of this table, be multiplied by ſec. H, ſec. h, as required by the formula. If greater preciſion be required, the whole calculation may be repeated with the corrected angle, inſtead of the obſerved angle.

Table V. is for calculating the ſpherical exceſs.

To make uſe of this table, it is neceſſary to have a plan of the triangles with a ſcale. The arguments are one ſide of the triangle as a baſe, and the height.

Example.

Obſerved Angle.	Zenith Diſtance.	Diſtance of Signals in Toiſes.
32° 20′ 15″.7	A = 89° 41′ 54″.6	A = 18283
	B = 88 49 15.6	B = 24423
	178 31 10.2	

$H + h = 1\ 28\ 49.8$
$H - h = 52\ 39$

	Tab. I.		Tab. II.	
Argument	H + h	H − h	P + Q	P − Q
Factors	+ 1.669	+ 0.587	− 0.112	− 0.003
Tab. IV.	+ 5.99	− 7.106	+ 5.99	− 7.106
	15021	3522	− 0.67	+ 0.2
	15021	0587	+ 0.02	
	8345	4109		
	+ 9.99731	−41.71222	− 0.65 = reduction to the chords.	

Obſerved angle	32° 20′ 15″.7
Reduction to horizon	31.7
Horizontal angle	= 32 19 44.0
Reduction to the chords	− 0.65
Angle of the chords	32 19 43.45

When the depreſſions are ſmall, we may, inſtead of the tables, uſe this formula.

$$x = \left\{\left(90° - \frac{\delta+\delta'}{2}\right)\text{tang.}\ \tfrac{1}{2}C - \left(\frac{\delta-\delta'}{2}\right)^2 \text{cot.}\ \tfrac{1}{2}C\right\} \text{fin. } 1''.$$

Example by the Formula.

$\delta = 89°\ 41'\ 54''.6$
$\delta' = 88\ 49\ 15.6$

$\delta + \delta' = 178\ 31\ 10.2$ $\quad \delta - \delta' = 0°\ 52'\ 39''$

$90° - \frac{\delta+\delta'}{2} = 0\ 44\ 24.9$ $\quad \frac{\delta-\delta'}{2} = 0\ 26\ 19.5$

$= 2664''.9 = p$ $\quad = 2579''.5 = q$

Sin. 1″	4.68557		4.68557
Log. p^2	6.85136	Log. q^2	6.39704
Tang. $\frac{1}{2}$C	9.46228	Cot. $\frac{1}{2}$C	0.53764
	+ 0.99921 = 9″.98		− 1.62025 = 41″.71
	− 41.71		
	− 31.73 = Reduction required.		
	32° 20′ 15.70		
Reduced angle =	32 19 43.97 the ſame as above.		

Reduction of the obſerved Angle to the Centre of the Station.

It frequently happens in trigonometrical ſurveys, that the obſervation cannot be taken in the centre of the ſtation; in this caſe, a correction becomes neceſſary.

(*Plate* VII. *fig.* 59.) Let C be the centre of the ſtation, O the place of the obſerver.

Then $ACB = AIB - CBO$
$= AOB + OAC - CBO$
or $C = O + A - B$

$$\text{Sin. A} = \text{ſin. OAC} = \frac{OC\ \text{ſin. AOC}}{AC} = \frac{r\ \text{ſin. (O + BOC)}}{D}$$

$$\text{hence } C = O + \frac{r\ \text{ſin. } (O + y)}{D\ \text{ſin. } 1''} - \frac{r\ \text{ſin. } y}{G\ \text{ſin. } 1''}$$

This formula is general, and ſuffers no exception.

C is the angle required at the centre; O, the obſerved angle;

angle; y is the angle between the left-hand object and the centre of the ſtation; r is the diſtance between the centre of the circle and the centre of the ſtation.

D, the diſtance of the object to the right.

G, the diſtance of the object to the left.

If $(O + y)$ exceed 180°, the firſt term is ſubtractive.

If the angle y exceeds 180°, the ſecond term becomes additive.

When the obſervation of the $\angle$ O is terminated, the upper teleſcope is always directed towards the left-hand object B, and the inferior towards the right-hand object A.—To obſerve the $\angle y$, the obſerver ſhould continue to keep the lower teleſcope on the object A, and let the upper one revolve from the right towards the left, till it points to the centre C.

This correction will be reduced to a ſingle term, when the diſtance of one object becomes infinite with reſpect to the other; as when one object is the ſun, or a ſtar, as is the caſe in obſervations for determining the azimuths of ſtations.

But this correction may become nothing without either of the diſtances becoming infinite; by which means it is ſometimes poſſible for the obſerver ſo to place his inſtrument as to reduce the correction to zero. This will be the caſe if it be on the circle which circumſcribes the given triangle A B C.

For then $\frac{\text{ſin. } y}{(\text{ſi}\ldots(O + y)} = \frac{G}{D}$;

and in the triangle A B C

$$\frac{\text{ſin. A}}{\text{ſin. B}} = \frac{\text{ſin. A}}{\text{ſin.(A + C)}} = \frac{G}{D}\text{; and ſince C} = O$$

$$\frac{\text{ſin. } y}{\text{ſin. C} + y} = \frac{\text{ſin. A}}{\text{ſin.(A + C)}}$$

Expanding the denominators

$$\frac{\text{ſin. } y}{\text{ſin. C cof. } y + \text{cof. C ſin. } y} = \frac{\text{ſin. A}}{\text{ſin. A cof. C} + \text{cof. A ſin. C}}$$

$$\text{or } \frac{1}{\text{ſin. C cof. } y \text{ cof. C}} = \frac{1}{\text{cof. C} + \text{cof. A ſin. C}}$$

and tang. y = tang. A = tang. 180° + A.

From this it appears, that if the obſerver has his choice of ſituation, he may place himſelf in ſuch a manner as to render any reduction unneceſſary; and to do this, he muſt be on the circumſcribing circle, or its tangent, at the point C, ſo that the angle y may be equal to A, or its ſupplement.

It however generally happens that the circumſtances which exclude the obſerver from the centre of the ſtation, at the ſame time prevent him from chooſing the exact point as determined above; but as the correction depends on the ſine of a certain angle, it is adviſable to render it as ſmall as poſſible, by ſelecting the moſt favourable poſition, particularly, if any difficulty ſhould occur in meaſuring the diſtance from the centre of the inſtrument to the centre of the ſtation.

If the diviſions are numbered from right to left, then *right* muſt be ſubſtituted for *left*, and *vice verſâ* in the preceding reaſoning.

It has been ſhewn, how, by having the oblique angle of two objects, A and B, as ſeen from a point C, we can obtain the horizontal or azimuthal angle; but it is neceſſary, for the truth of our concluſion, that the point C remain the ſame for the zenith diſtance obſervations as for the oblique angles. If we examine the conſtruction of the repeating circle, we ſhall find that its centre C is lower in the vertical than in the horizontal poſition: this circumſtance ſeems to have been overlooked by the French aſtronomers; or they have probably included it in the requiſite correction employed for the difference of height of the ſignal above the centre of the circle. To apply this correction, we are to conſider what would be the zenith diſtance of an object if the centre of the inſtrument were elevated or depreſſed a given quantity.

The correction is as follows:

Let dH be the difference of altitude of the two poſitions, D the diſtance of the obſerved ſignal, δ the zenith diſtance required to be corrected; then the corrected diſtance will be

$$\delta + \left(\frac{\delta\,\text{H}}{\text{D}}\right)\frac{\text{ſin. } \delta}{\text{ſin. } 1''}.$$

If the inſtrument is advanced before the ſignal, the diſtance corrected $= \delta + \left(\frac{r}{\text{D}}\right)\frac{\text{cof. } \delta}{\text{ſin. } 1''}$; r being the diſtance of the centre.

In Mr. Troughton's circles the centre of the circle is 5.4, or 5.5 inches lower in the vertical than in the horizontal poſition.

When the Signal is unequally illuminated.

When the ſignal is unequally illuminated by the ſun, the obſerved point is neither in the axis, nor in the direction of the axis. For example, *fig.* 63. let *a b c d* be a ſection of a ſignal of four ſides, if *a b* or *a c* only is ſufficiently enlighténed to be viſible, the obſerver will direct the optic axis of his teleſcope to A or B inſtead of the centre M. and the angle obſerved will require a correction equal to A O M or B O M. Let P = perpendicular M A, A = angle A M O, D equal the diſtance O M; the correction c will then be $c = \frac{\text{P ſin. A}}{\text{D ſin. } 1''}$.

This correction is ſubtractive, if the obſerved point is to the $\left\{\begin{matrix}\text{right}\\\text{left}\end{matrix}\right\}$ of the centre in the object to the $\left\{\begin{matrix}\text{right}\\\text{left}\end{matrix}\right\}$. It is additive, if the obſerved point is to the $\left\{\begin{matrix}\text{left}\\\text{right}\end{matrix}\right\}$ of the centre in the object on the $\left\{\begin{matrix}\text{right}\\\text{left}\end{matrix}\right\}$.

If the ſignal be a round tower or maſt of ſenſible diameter, the calculation is ſomething longer, becauſe the azimuth of the ſun influences the quantity of the correction.

Let an obſerver in O be ſituated ſo far from the round tower (*fig.* 62.) A P S P, as to be unable to ſee the part not illuminated by the ſun; he will direct his view to the middle of the illuminated part, inſtead of the centre of the whole.

Let N M be the meridian line, M C S the azimuth of the ⊙, the ſemicircle A S B will be illuminated by the ſun to the extremity A, of the enlightened part, draw O A, and on the other ſide the viſual ray O E, tangent to the tower; the viſible part A P S E will be unequally divided by O G. If x be the azimuth of the obſerver, z the azimuth of the ſun, d = C E, and D = O C, the correction will be $\text{C} = \frac{d\,\text{ſin.}^2\,\frac{1}{2}(x - z)}{\text{D ſin. } 1''}$.

$x - z$ may be either calculated or obſerved. By calculation:

$$\text{Cof. } z = \text{ſin. L cof. H} - \frac{\text{cof. L tang. B}}{\text{ſin. H}}$$: L being the lat., B the declination of the ſun, and H the hour angle.

To obſerve $x - z$, take the horizontal angle between the

the ſun and tower by the azimuth circle, which will always be exact enough for this correction.

On the Calculation of the Triangles.

When the obſerved angles are reduced to the horizon by the method above ſtated, the triangles may be either conſidered as rectilinear, ſpherical, or ſpheroidical: the firſt caſe ſuppoſes the angles reduced to their chords, and that the ſides of the triangles become the edges of an irregular polyhedron inſcribed within the terreſtrial ſpheroid; the baſe in like manner ſhould be reduced to a chord line, by ſubducting from its meaſured length the exceſs of the arc above the chord.

But the ſpherical computation is rendered very eaſy by a theorem firſt inveſtigated by Legendre, by which it appears that a ſpherical triangle, whoſe ſides are very ſmall, may be calculated without ſenſible error by the rules of plane trigonometry, provided a ſmall correction be firſt made in the obſerved angles.

When the Engliſh ſurvey was firſt began, this theorem was unknown; and general Roy, who was the firſt perſon that had taken the ſpherical exceſs into his calculations, corrected his triangles in a more arbitrary manner than he would have done, had he been aware of the curious property abovementioned. By this theorem is derived a more accurate method of correcting the angles for computation. One third of the ſpherical exceſs, as found by obſervation, ſhould be ſubtracted from each angle, and the ſides calculated as if they were rectilinear. For the demonſtration of this theorem, ſee Legendre's Treatiſe on Geometry. Colonel Mudge and Delambre prefer reducing the angles to chord lines; this method, when the three angles are all obſerved, is perfectly accurate; but when one angle only is obſerved and the reſt inferred, as in calculating diſtances from the meridian and its perpendicular, the method of Legendre ſeems to be the moſt eaſy and leaſt liable to error.

General Principles of the Method of tracing and calculating a Meridian Line.

If we imagine a plane paſſing through the axis of the earth and the zenith of any place; this plane, extended to the limits of the celeſtial ſphere, will there trace a great circle, which will be the meridian of that place: and if a line be drawn through all the points of the ſurface of the globe, which have their zenith in this circle, it will form the correſponding terreſtrial meridian. From the immenſe length of the radius of the heavens, the verticals of all theſe points may be conſidered as parallel to the plane of the celeſtial meridian: ſo that the terreſtrial meridian may be defined a curve paſſing through and connecting thoſe points, in which all the verticals parallel to the plane of the celeſtial meridian interſect the ſurface of the earth. This curve will deviate from the above plane, if the earth be an irregular ſpheroid, and be a curve of double curvature; but, on the contrary, will lie entirely in it, if it be a ſphere, or any regular figure of revolution.

If in any given point, we fix a ſignal, and by means of the optic axis of a teleſcope, directed exactly north or ſouth of that ſignal, we place others in this axis, and by removing the teleſcope continue, in the ſame manner, to place other ſignals in the ſame direction, we ſhould trace a meridian line. But as this method would be inconvenient, if not impoſſible in practice, we follow, as has been ſeen above, another method which leads us to the ſame reſult.

Let A B C D E, *Plate* VII. *fig.* 60, be a chain of triangles extended in the direction of the meridian, and whoſe ſides may be conſidered as arcs of the terreſtrial ſpheroid. Suppoſe, by an obſervation of the azimuth, the inclination or direction of the ſide A C with the firſt ſide of the meridian A M be known. The point M, where this curve cuts B C, may be found by trigonometry. The points A, B, C, being in the ſame horizontal plane, A M will likewiſe be in the ſame plane; but from the curvature of the earth the continuation of this line, M M′, will be above the ſurface of the next triangle B C D: if then, without changing the angle C M M′, the line M M′ be bent down to the plane of the triangle B C D, by ſuppoſing it to turn round B C as an axis, the point M′ will deſcribe a ſmall arc of a circle which may be conſidered as a ſtraight line perpendicular to the plane B C D.

From this it follows, that the operation conſiſts in bending down this line in the direction of a vertical, and in calculating the diſtance M M′, to find the point M′.

By carrying on the meridian line in this manner through the whole ſeries of triangles, we may by trigonometrical calculation find the direction and length of this meridian from one extremity to the other.

If the earth be of an irregular figure, this line differs a little from the terreſtrial meridian; but it always has this property, that it is the ſhorteſt line that can be drawn between its two extremities, over the ſurface of the earth.

Now, if we imagine a great circle perpendicular to the celeſtial meridian, paſſing through the zenith of the place of the obſerver, this circle will repreſent the prime vertical of that place. A curve connecting all the points on the ſurface of the earth, which have their zenith in this circle, will form the perpendicular to the meridian, which may be traced in the ſame manner as the meridian itſelf.

In the ſphere theſe perpendiculars are great circles which cut each other on the equator. But on the ellipſoid, and ſtill more if that be irregular, theſe perpendiculars will be curves of double curvature.

Whatever be the nature of the terreſtrial ſpheroid, the parallels to the equator are curves in which all the points have the ſame latitude.

The ſituation of a place is determined when the perpendicular to the meridian or its parallel is known, and alſo the ſituation of the place on this perpendicular or parallel.

When, therefore, a ſeries of triangles and their direction have been calculated according to the principles already explained, we obtain the poſition of the ſummits of all their angles, by means of their co-ordinates, or diſtances from the perpendicular, and from the meridian of the principal ſtation.

Suppoſe the triangles A B C, B C D, to make part of a chain of other triangles whoſe ſides are arcs of great circles of a ſphere, having for its radius the diſtance of the centre of the earth to the ſurface of the ſea, and that the angle C A X, which meaſures the azimuth Z of the ſide A C, or its inclination to the meridian, has been determined by obſervation; we muſt firſt calculate the ſpherical exceſs ε in the right angled triangle A c C, and then reſolve it by the two following proportions:

Sin. $(90° - \frac{1}{3}\varepsilon)$: cof. $(z - \frac{1}{3}\varepsilon)$: : A C : A $c = x$.

Sin. $(90° - \frac{1}{3}\varepsilon)$: ſin. $(z - \frac{1}{3}\varepsilon)$: : A C : C $c = y$.

The azimuth of A B is known, becauſe $\angle$ B A X = $\angle$ C A B − C A X; and by calculating the ſpherical exceſs of the triangle A B M′, we have A M′ B = 90° − M′ A B − A B M′ + ε.

To determine the ſides A M′, B M′, we muſt deduct $\frac{1}{3}$ of the ſpherical exceſs, $\frac{1}{3}\varepsilon$, from each of the angles of the triangle A B M′, to obtain theſe proportions.

Sin. $(90° - A - B + \frac{2}{3}\varepsilon)$: ſin. $(B - \frac{1}{3}\varepsilon)$: : A B : A M′.

Sin. $(90° - A - B + \frac{2}{3}\varepsilon)$: ſin. $(A - \frac{1}{3}\varepsilon)$: : A B : B M′.

In

In each of the right angled triangles, A *b* B, M′ *d* D, two angles and the hypothenuſe are known, and thus the ſides A *b*, *b* B, M′ *d*, *d* D, may be found. Therefore the diſtances of the points, B, D, from the meridian and its perpendicular are known.

Proceeding in this manner in the triangle A C N or M′ D N, to obtain A N and D N, the continuation of C D, and in the triangle D N F to get the ſide N F, and the angles D N F, D F N, we ſhall be able to determine the co-ordinates.

The diſtance *f* F, and the angles D F N, N F *f*, being known, we have *f* F P = 90° — E F D — D F N — N F *f*; ſince all the horizontal angles about a given ſtation are together equal to four right angles.

Since two angles and a ſide are known in the right angled triangle *f* F P, we may calculate the ſpherical exceſs and the angle F P *f* and the other ſides *f* P, F P. Then by reſolving the right angled triangle *e* E P, the co-ordinates of E with reſpect to the meridian A X, and its perpendicular A Y, may be found. It is adviſable to make a ſcale of the obſerved chain of triangles, to ſee if any ſuch as A C N, M′ E P, which have been formed to facilitate the calculation, may not be too obtuſe or too acute to be employed with ſafety.

This method may be very properly employed for determining the length of an arc of the meridian, when the triangles do not deviate from the meridian line; and as the azimuths of a great number of ſides are found, theſe may be verified by direct obſervation.

In a memoir of Legendre, of which the following is an extract, he ſhews a method of calculating a meridian line, without drawing perpendiculars from the ſeveral ſtations.

When all the angles of the triangles are reduced to the horizon, and the correction neceſſary to reduce the ſum of the angles to 180 + the ſmall exceſs due to the area applied to the angles, and calculated *à priori*, the inequality of the heights of the ſtations need no longer be regarded, and the whole chain of triangles may be regarded as projected on a ſpherical or ſpheroidical ſurface, which may be conſidered as an extenſion of the ſurface of the ſea.

In this hypotheſis, which ſeems the moſt proper for ſimplifying the calculation, the triangles become ſpherical or ſpheroidical. The ſides are, or ought to be, conſidered as arcs of a circle, and the baſe, which is equally an arc of a circle, may be eaſily deduced from the meaſured baſe, by applying to it a correction calculated from the known height of the two extreme points above the level of the ſea. This being granted, we may employ the theorem given in the memoirs of the academy for the year 1787, to calculate the different ſides of the projected chain of triangles. Conſequently, if in the propoſed triangle the ſum of the angles is 180 + w, we muſt take away $\frac{1}{3}$ w from each angle to reduce the ſum to 180. This ſubtraction being made, we may proceed as if the given triangle was rectilinear. That is to ſay, we may deduce this proportion: the ſine of an angle oppoſite to a given ſide is to that ſide as the ſine of another angle is to its oppoſite ſide. The fourth term will be the length of the ſide of the ſpherical triangle we wiſh to reſolve; and which can thus be found with as much facility, as if the chain of triangles was ſituated entirely in the ſame plane. It has been propoſed to calculate the ſame ſpherical triangles by means of rectilinear triangles formed by reducing the ſides to their chords. But for this method we muſt determine the difference between each angle of the ſpherical triangle, and the correſponding angle of the rectilinear triangle, by a ſeparate operation. It is evident that this method muſt be leſs ſimple, and more ſubject to error than the one we have mentioned.

Let A, B, C, D, E, F, &c. (*Pl.* VII. *fig.* 61.) be a chain of triangles, a little diſtant from the meridian, and traced upon a curved ſurface, repreſenting the level of the ſea. We ſuppoſe the angles and ſides of the triangles known, by the operation already deſcribed. We may know by obſervation the angle, C A M, which meaſures the azimuth of the ſide, A C, or its inclination relative to the meridian. It is required to find the length of the meridian, A X, prolonged till it meets the perpendicular, L X, let fall from the laſt point of the chain. For this purpoſe we ſhall follow the ſame principles, as in the reſolution of the triangles. But we may, according to circumſtances, find means to abbreviate, and to avoid the calculation of as many parts of the meridian as there are triangles

In the figure propoſed, having prolonged C D to M, the triangle A C M muſt be reſolved, in which the ſide, A C, and the two adjacent angles, C A M, and A C M, are known. The value of the ſpherical exceſs, w, in this triangle, muſt then be calculated to get the repreſentative of C M A. By means of theſe three angles, and the known ſide, A C, we may determine the two ſides, A M, and C M, by the ſame proportion as if the triangle was rectilinear. The value of M O is obtained by reſolving the quadrilateral figure, D M O F, in which the angles M, D, F, and the ſides D M, D F, are known. Let the diagonal, M F, be drawn, the triangle, D M F, muſt then be computed, in which the ſides, D M, D F, and the included angle, D, are known. For this purpoſe we may proceed as if the triangle D M F was rectilinear, recollecting previouſly to ſubtract one-third of the ſpherical exceſs due to the area of the triangle from the angle, M D F. By theſe means we ſhall find the ſide, M F, and the two angles, D M F, D F M, to each of which we muſt add $\frac{1}{3}$ w. Proceeding then to the triangle M F O, the ſide, M F, and the two adjacent angles are known; the ſides, M O, F O, and the angle, M O F, may be found in the uſual manner. In the triangle, O P H, having given the ſide, O H, and the two adjacent angles, O P, P H, and the angle O P H, may be determined. The remainder of the meridian, P X, may now be found by the reſolution of the triangles, P H K, P Q K, and Q L X. But it is a more ſimple method to prolong the arc J L, and to determine P X, by the triangles, P J Z, and L X Z: in this laſt the hypothenuſe, L Z, the angle Z, and the right angle, X, are known. Then after having determined the valve of w, proper for this triangle, it may be reſolved by the following proportion:

Sine (90 — $\frac{1}{3}$ w) : L Z : : (Cof. Z — $\frac{1}{3}$ w) : X Z.

All the caſes that can occur in this operation are collected in the figure given as an example, and no farther difficulty can exiſt in the application of this method. In general the very ſmall quantity, w, varies from one triangle to another, and ſhould be determined *à priori*, for each of the triangles to be reſolved. One-third of this quantity ſhould be ſubtracted from each angle of the ſpherical triangle, to enable us to employ the rules of rectilinear trigonometry. But the reſult being found, we ſhould add one $\frac{1}{3}$ w to every angle. We have given an example of the reſolution of a quadrilateral figure, D M F O, in which two ſides and three angles are known. As this calculation is a little more difficult than ordinary ones, it might be avoided by prolonging the two ſides E D, E F, and reſolving the triangles, R D M, R E N, and F N O. But here are three triangles to be calculated inſtead of two, ſo that the firſt method ſeems preferable. By this operation the azimuths of many ſides of the chain are found at the ſame time, that is, the angles which theſe ſides make with the meridian. If then theſe azimuths have been pre-

viouſly determined in two different places, as is uſually done, at the two extremities of the chain, we ſhall have a very ſimple method of verification, ſince the calculated and obſerved azimuths ought to agree.

It muſt finally be obſerved, that the point X has rather greater latitude than the point L. Let λ be the latitude of the point L, r the radius of curvature of the meridian towards L, y the diſtance L X, R the number of ſeconds, compriſed in the radius of the tables, we ſhall find that the latitude of the point X is $\lambda + \frac{1}{2} R \left(\frac{y}{r}\right)^2$ tang. λ, where the correction will be expreſſed in ſeconds.

Though the different portions of a meridian line may be calculated by either of theſe methods, yet the problem in its more extended ſignification uſually embraces many other conſiderations. Having given the latitude of an extreme point of a terreſtrial arc, and the inclination of one ſide of the triangles to the meridian, it is required to determine by calculation the latitudes of all the ſtations, their azimuths with regard to each other, and their difference of longitude from the point of departure, the diſtance between the parallels of any two ſtations, and laſtly the arc of the meridian intercepted by the extreme ſtations. When the triangles are large, and diverge conſiderably from the meridian, the computation to be correctly made ſhould be founded on ſome hypotheſis of the figure of the earth; that is to ſay, the triangles ſhould be conſidered not as ſpherical but ſpheroidical. A very uſeful theorem is given in the Engliſh ſurvey, for the calculation of theſe triangles; and we ſhall extract from Puiſſant's "Traité de Geodeſie" an inveſtigation of the formulæ, which form the baſis of the practical rules given by Delambre and Legendre.

The principal object of theſe formulæ is to obtain algebraical expreſſions for computing the value of the following quantities:

The radius of a circle parallel to the equator in any latitude;—the normal, or radius of curvature of a great circle perpendicular to the meridian;—the radius of the earth, or the line drawn from its centre to any point where latitude is known;—the radius of curvature to any part of the arc of the meridian;—the quarter of the meridian in terms of a meaſured arc, and of the latitude of its extremities;—the compreſſion, or ellipticity of the terreſtrial ſpheroid, deduced from a meaſure of two arcs;—the eccentricity;—the length of a ſtandard meaſure as the French metre, which is aſſumed equal to the $\frac{1}{10000000}^{th}$ part of the meridian.

Inveſtigation of Formulæ for expreſſing in Terms of the Latitude different Parts of the Meridian, the Earth being ſuppoſed an ellipſoid of Revolution.

Let CE be radius of the equator (*fig.* 64.): P the pole.

If from the point A a tangent AT be drawn to the elliptic arc BAE; MA will be the normal to the point A, and $\angle$ALT $=$ $\angle$FAT $=$ latitude of the point A.

The equation to the ellipſe is $a^2 y^2 + b^2 x^2 = a^2 b^2$; and for the point A, whoſe co-ordinates are x', y', we have $a^2 y'^2 + b^2 x'^2 = a^2 b^2$. At the ſame point A the equation to the normal AL is $y - y' = \frac{a^2 y'}{b^2 x'} \cdot (x - x')$; if $y = o$, then CL or $x = \frac{a^2 - b^2}{a^2} x'$; from which it is eaſy to conclude that the normal $AL = n = \frac{b}{a}\left(b^2 + \frac{a^2 - b^2}{b'^2} y'^2\right)^{\frac{1}{2}}$.

Let ALF $=$ L, then $y' = n$ ſin. L; and conſequently $y'^2 = \frac{b^2}{a^2}\left[b^2 + \frac{a^2 - b^2}{b^2} y'^2\right]$ ſin.^{2} L; hence $y'^2 = \frac{b^4 \text{ ſin.}^2 \text{ L}}{a^2 - (a^2 - b^2) \text{ ſin.}^2 \text{ L}}$. (1).

And $n = \frac{b^2}{a}\left[1 - \frac{a^2 - b^2}{a^2} \text{ ſin.}^2 \text{ L}\right]^{-\frac{1}{2}}$. (2).

If in this equation we put $a = 1$ and $\frac{b}{a}$ and b' we ſhall have $\frac{a^2 - b^2}{a^2} = e^2$; or $1 - b'^2 = e^2$, e expreſſing the eccentricity: then $n = (1 - e^2)(1 - e^2 \text{ ſin.}^2 \text{ L})^{-\frac{1}{2}}$ $\frac{1 - e^2}{(1 - e^2 \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}}$. (3).

And the equation (1) will become $AF = y' = \frac{(1 - e^2) \text{ ſin. L}}{(1 - e^2 \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}}$. (4).

In the ſame hypotheſis the equation of the ellipſe is changed into $y'^2 = (1 - e^2)(1 - x'^2)$ and by the preceding equation $CF = x' = \frac{\text{coſ. L}}{(1 - e^2 \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}}$. (5).

This is the value of the radius of a parallel of latitude to the point A.

In the ſame manner, the value of CL, found as above, may be changed into $CL = e^2 x'$; but x' is given in equation (5); therefore $CL = \frac{e^2 \text{ coſ. L}}{(1 - e^2 \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}}$. (6).

All the values thus obtained, are relative to the greater axis taken as the line of x.

The ſame mode of calculation will lead us to the values of AM and CM, &c.

Let $a^2 x^2 + b^2 y^2 = a^2 b^2$, and let the values of x be now taken on the leſſer axis. Let the normal $AM = n'$, we ſhall have for the point A; $y^2 = n'^2$ coſ.^{2} L; but if in equation (2) a be changed into b and *vice verſâ*, and ſine for coſine $AM = n' = \frac{a^2}{b}\left(1 - \left(\frac{b^2 - a^2}{b^2}\right) \text{ coſ.}^2 \text{ L}\right)^{\frac{1}{2}}$, and ſince $b = b'$ when $a = 1$,

$$n' = \frac{1}{(1 - e^2)^{\frac{1}{2}}\left[1 + \frac{e^2}{1 - e^2}(1 - \text{ſin.}^2 \text{ L})\right]^{\frac{1}{2}}} = \frac{1}{(1 - e^2 \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}}. \quad (7).$$

Since $y^2 = n'^2$ coſ.^{2} L $y^2 = \frac{\text{coſ.}^2 \text{ L}}{1 - e^2 \text{ ſin.}^2 \text{ L}}$.

By the equation of the ellipſe $y^2 = \frac{(1 - e^2) - x^2}{1 - e^2}$ from whence we may deduce $x^2 = \frac{(1 - e^2)^2 \text{ ſin.}^2 \text{ L}}{1 - e^2 \text{ ſin.}^2 \text{ L}}$.

As we have found above $CL = \frac{a^2 - b^2}{a^2} x'$; we ſhall in the preſent caſe have $CM = \frac{b^2 - a^2}{b^2} x = \frac{-e^2}{1 - e} x$; ſubſtituting for x its value in the preceding equation, we obtain $CM = \frac{-e^2 \text{ ſin. L}}{(1 - e \text{ ſin.}^2 \text{ L})^{\frac{1}{2}}} = -e^2 n' \text{ ſin. L}$. (8).

As to the value of AC, it is evidently repreſented by $\sqrt{x^2 + y^2}$, ſo that whether we take the above values of x^2,

x'', y'', or have recourſe to the equations (4) and (5), we have equally $AC = r = \left[\frac{e^2 (1 - e^2) \text{ fin.}^2 L}{1 - e^2 \text{ fin.}^2 L}\right]$. (9).

This formula is ſuſceptible of a more commodious form: Imagine a ſphere circumſcribing the ellipſoid, which has for its radius that of the equator, the angle $C\,a\,E = F\,a\,T = \lambda$ will be the latitude of the point a on the ſphere; but the points A, a, have the ſame abſciſſe C F; therefore if we take $AF = y'$ and $aF = y''$, the equations of the circle and ellipſe will be reſpectively $\left\{\begin{matrix} y'^2 = 1 - x^2 \\ y'^2 = b'^2 (1 - x^2) \end{matrix}\right\}$ eliminating x^2; $y'^2 = b'^2 y''^2$.

But a F is the ſine of λ, ſince $aC = 1$, therefore ſine $^2\lambda = \frac{(1 - e^2) \text{ fin.}^2 L}{1 - e^2 \text{ fin.}^2 L}$ and the equation (9) becomes $AC = (1 - e^2 \text{ fin. } ^2\lambda)^{\frac{1}{2}}$. (10).

Now to find the value of λ, divide in the preceding equations of the two curves one by the other, and $\frac{y'}{y''} = b'$.

By inſpection of the figure it will be ſeen that $\frac{y'}{FT} = \frac{1}{\text{tang. L}}$ and $\frac{y''}{FT} = \frac{1}{\text{tang. } \lambda}$ therefore $\frac{y'}{y''} = \frac{\text{tang. } \lambda}{\text{tang. L}}$.

From theſe two values of $\frac{y'}{y''}$ it reſults that tang. $\lambda = b'$ tang. L.

If B be taken ſuch that cof. $B = b'$, then $1 - b' = 1 - \text{fin. } ^2\frac{1}{2}B$, cof. B. $= 2 \text{ fin.}^2 \frac{1}{2}B$, tang. λ = cof. B tang. L, and 2 cof.$^2 \frac{1}{2}B = 2 - 2 \text{ fin.}^2 \frac{1}{2}B = 1 + b'$, therefore tang.$^2 \frac{1}{2}B = \frac{1 - b}{1 + b'}$, and by the expanſion of a trigonometrical formula, $L - \lambda = \text{tang.}^2 \frac{1}{2} B \text{ fin. } 2L - \frac{1}{2} \text{tang.}^4 \frac{1}{2} B \text{ fin. } 4L + \frac{1}{2} \text{tang.}^6 \frac{1}{2} B \text{ fin. } 6L$, &c.

$$L - \lambda = \left(\frac{1 - b'}{1 + b'}\right) \text{fin. } 2L - \frac{1}{2}\left(\frac{1 - b'}{1 + b'}\right)^2 \text{fin. } 4L + \frac{1}{3}\left(\frac{1 - b'}{1 + b'}\right)^3 \text{fin. } 6L.$$

This ſeries is rendered very converging by introducing the ratio of the axis of the ellipſe $m : n$, for $b' = \frac{n}{m}$ and $\frac{1 - b'}{1 + b'} = \frac{m - n}{m + n} = \frac{1}{m + n}$ for m, n generally differ but one unit from each other: thus $L - \lambda = \left(\frac{1}{m + n}\right) \text{fin. } 2L - \frac{1}{2}\left(\frac{1}{m + n}\right)^2 \text{fin. } 4L + \frac{1}{3}\left(\frac{1}{m + n}\right)^3 \text{fin. } 6L$, ſince $m = 334$, $n = 333$ nearly. The firſt term of this ſeries is ſufficient.

Thus, to find AC; in the expreſſion of its value $(1 - e^2 \text{ fin.}^2 \lambda)^{\frac{1}{2}}$, ſubſtitute for λ its equal as found above.

To find an expreſſion for the radius of curvature of the meridian, it ſhould be remembered that in curves of the ſecond order it is always equal to the cube of the normal divided by one quarter the ſquare of the parameter.

Therefore for the lat. L

$$R = \frac{n^3}{\frac{1}{4}p^2} = \frac{(1 - e)^3 (1 - e^2 \text{ fin. } ^2L)^{-\frac{3}{2}}}{\frac{1}{4}p^2};$$

but $\frac{1}{4}p^2 = \frac{b^4}{a^2} = (1 - e^2)^2$, hence $R = (1 - e^2)^2 (1 - e^2 \text{ fin.}^2 L)^{-\frac{3}{2}}$. (11).

If this value be required in terms of the ellipticity of the earth, the longer or equatorial axis being taken as unity, let $\frac{a - b}{a} = \alpha$, and becauſe $1 - b'^2 = e^2$ and $b' = 1 - \alpha$

$$e^2 = 1 - (1 - \alpha)^2 = 2\alpha - \alpha^2,$$

hence $R = (1 - 2\alpha + \alpha^2)(1 - (2\alpha - \alpha^2) \text{ fin.}^2 L)^{-\frac{3}{2}}$.

Expanding this negative power, and rejecting the ſecond powers and thoſe above, we have

$$R = 1 - \alpha (2 - 3 \text{ fin.}^2 L). \quad (12).$$

We may proceed now to the rectification of the curve or arc of the meridian.

Let S = arc between the equator and the point whoſe latitude is L its differential.

$$dS = \sqrt{dx'^2 + dy'^2} = dx' \sqrt{\frac{1 - e^2 x'^2}{1 - x'^2}};$$ (vid. La-croix cal. diff.) Since $x' = \frac{\text{cof. L}}{\sqrt{1 - e^2 \text{ fin.}^2 L}}$ (equal 5.)

$$dx' = \left\{ \frac{d \text{ cof. L}}{\sqrt{1 - e^2 \text{ fin.}^2 L}} - \frac{1}{2} \frac{\text{cof. L } d(1 - e^2 \text{ fin.}^2 L)}{(1 - e^2 \text{ fin.}^2 L)^{\frac{3}{2}}} \right.$$

But when x' increaſes, L diminiſhes; therefore

$$dx' = -dL \text{ fin. L} \left(\frac{-1}{(1 - e^2 \text{ fin.}^2 L)^{\frac{1}{2}}} + \frac{e^2 \text{ cof.}^2 L}{(1 - e^2 \text{ fin.}^2 L)^{\frac{3}{2}}}\right)$$
$$= \frac{(1 - e^2) \text{ fin. L } dL}{(1 - e^2 \text{ fin.}^2 L)^{\frac{3}{2}}}$$

In the expreſſion for dS, for x' and dx', ſubſtitute their values as above; and

$dS = (1 - e^2)(1 - e^2 \text{ fin.}^2 L)^{-\frac{3}{2}} dL -$, and by the binomial theorem.

$$\frac{dS}{1 - e^2} = \left\{ 1 + \tfrac{3}{2} e^2 \text{ fin.}^2 L + \tfrac{3}{2} \cdot \tfrac{5}{4} e^4 \text{ fin. } ^4L + \tfrac{3}{2} \cdot \tfrac{5}{4} \cdot \tfrac{7}{6} e^6 \right.$$
$$\left. \text{fin. } ^6L + \right\} dL;$$

then, by changing the powers of the ſines and coſines of the multiple arcs (vid. La Croix's Diff. Cal. N° 199.)

$$\frac{dS}{(1 - e^2)} = \left\{ 1 + \frac{3}{2} \cdot \frac{2}{1.2^2} e^2 + \frac{3 \cdot 5}{2 \cdot 4} \cdot \frac{4 \cdot 3}{1 \cdot 2 \cdot 2^2} e^4 + \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6} \cdot \right.$$
$$\left. \frac{6 \cdot 5}{1 \cdot 2 \cdot 3 \cdot 2^6} \cdot \frac{4}{} e^6 + \right\} dL$$
$$- \left\{ \frac{3}{2} \cdot \frac{1}{2} e^2 + \frac{3 \cdot 5}{2 \cdot 4} \cdot \frac{4}{2^3} e^4 + \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6} \cdot \frac{6 \cdot 5}{1 \cdot 2 \cdot 2^5} \right.$$
$$\left. e^6 \right\} dL \text{ cof. } 2L$$
$$+ \left\{ \frac{3 \cdot 5}{2 \cdot 4} \cdot \frac{1}{2^3} e^4 + \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6} \cdot \frac{6}{1 \cdot 2^5} e^6 \right\} dL \text{ cof. } 4L$$
$$- \left\{ \frac{3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6} \cdot \frac{1}{2^5} e^6 + \right\} dL \text{ cof. } 6L:$$

Or, for conciſeneſs,

$$\frac{dS}{(1 - e^2)} = m\,dL - n\,dL \text{ cof. } 2L + p\,dL \text{ cof. } 4L - q\,dL \text{ cof. } 6L;$$ and by integration,

$$\frac{S}{1 - e^2} = m L - \frac{1}{2} n \text{ fin. } 2L + \frac{1}{4} p \text{ fin. } 4L - \frac{1}{8} q \text{ fin. } 6L + (13).$$

Here the integral is complete, ſince the arc S vaniſhing at the ſame time as L, the conſtant quantity neceſſarily becomes nothing.

It is evident that for another arc S, terminating in the latitude L'

1 =

$\frac{S'}{1-e^2} = m\,L' - \frac{1}{2}n \sin. 2\,L' + \frac{1}{4}p \sin. 4\,L' - \frac{1}{8}q \sin. 6\,L +$ &c.; consequently the arc $S - S'$ compriſed between the latitudes L and L′ will be given by the equation.

$$\frac{S-S}{1-e^2} = m\,(L - L') - \frac{1}{2}n\,(\sin. 2\,L - \sin. 2\,L') + \frac{1}{4}p\,(\sin. 4\,L - 4\,L') - \frac{1}{8}q\,(\sin. 6\,L - 6\,L') +$$
$$= m\,(L - L) - n \sin. (L - E) \cos. (L + L) + \frac{1}{2}p \sin. 2\,(L - L') \cos. 2\,(L + L') - \frac{1}{4}q \sin. 3\,(L - L') \cos. 3\,(L + L'.) \quad (14).$$

If Q repreſent a quarter of the meridian, L will be equal 90°; and equation (13) gives

$$\frac{Q}{1-e^2} = m\,90°.$$

Dividing this by the preceding

$$\frac{Q}{S-S'} = \frac{90°}{(L-L') - \frac{m}{n} \sin. (L-L') \cos. (L+L') + \frac{1}{2}\frac{p}{m} \times \sin. 2\,(L-L') \cos. (L+L') - \frac{1}{4}\frac{q}{m} \sin. 3\,(L-L') \over \cos. 3\,(L+L'.)}$$

But, (rejecting the terms above e^4,)

$$m = 1 + \frac{3}{4}e^2 + \frac{45}{64}e^4$$
$$\frac{n}{2} = \frac{3}{8}e^2 + \frac{15}{32}e^4$$
$$\frac{1}{4}p = \frac{15}{256}e^4$$
$$\frac{n}{m} = \frac{3}{4}e^2 + \frac{3}{8}e^4$$
$$\frac{1}{2}\frac{p}{m} = \frac{15}{128}e^4$$

$$Q = \frac{(S-S')\,90°}{L-L'}\left(1 + \frac{3}{4}e^2 + \frac{3}{8}e^4\right)\frac{\sin. (L-L') \cos. (L+L')}{L-L'} - \frac{15}{128}e^4 \frac{\sin. 2\,(L-L') \cos. 2\,(L-L')}{L-L'} \quad (15).$$

To employ this formula, which gives Q in the ſame meaſure as the arc $S - S'$ (and in which the two terms of the fraction $\frac{90°}{L-L'}$ ought to be of the ſame kind) $L - L$ ſhould be reduced into parts of the radius, and $\frac{1}{2}\pi$ (or 1.5707963267) ſubſtituted for 90°.

When $L + L' = 90°$; $\cos. (L + L')^4 = 0$, and then without ſenſible error $Q = \frac{(S-S')\,90°}{L-L'}$; that is to ſay, that the value of the quarter of the meridian is independent of the ellipticity, and that the degree at 45° is very nearly the 90th part of the quadrant.

In the ſame circumſtance the equation (14) gives $S - S' = (1 - e^2)\,m\,L - L'$.

And $Q = m\,(1 - e^2)\,\frac{1}{2}\pi$

Exterminating m; the radius of the equator being repreſented by unity

$$Q = \frac{1}{4}\pi\left(1 - \frac{1}{4}e^2 - \frac{3}{64}e^4 - \frac{5}{256}e^6\right) \quad (16).$$

The ſame as may be obtained by formulæ (13), by making $L = 90°$.

To uſe the above formulæ, it is neceſſary previouſly to determine the elements they contain; theſe are, the eccentricity, e, or the compreſſion, α: and as theſe formulæ are relative to an ellipſe whoſe greater axis is 1, they muſt be multiplied by the equatorial radius expreſſed in ſome ſtandard meaſure, as feet or metres, &c. whenever we apply them to the terreſtrial meridian.

And firſt to find the compreſſion α.

Let g, g' be the meaſured value of two degrees, let L, L′ expreſs the angles which the reſpective normals paſſing through the centres of theſe degrees make with the greater axis $= \pi$ the circumference of a circle whoſe radius $= 1$. R, R′, the radii of curvature we have by formula (12).

$$R = a(1 - \alpha\,(2 - 3 \sin.^2 L')$$
$$R' = a(1 - \alpha\,(2 - 3 \sin.^2 L')$$

The ſemi-circumference of which R is the radius $= \pi R$, and it intercepts 180°, conſequently,

$$g = \frac{\pi R}{180}\,g' = \frac{\pi R'}{180} \text{ ſo that}$$
$$\frac{g'}{g} = \frac{1 - \alpha\,(2 - 3 \sin.^2 L)}{1 - \alpha\,(2 - 3 \sin.^2 L')}$$

Reducing this fraction, and neglecting the terms α^2, &c.

$$\frac{g'}{g} = 1 - 3\,\alpha\,(\sin.^2 L - \sin.^2 L')$$

From whence the value of α is found.

$$\alpha = \frac{g - g'}{3g\,(\sin.^2 L - \sin.^2 L'.)}$$

The equation $\alpha = \frac{g' - 3}{3\,g \sin.^2 L''}$, gives $g'' = g\,(1 + 3\,\alpha \sin.^2)L''$, if we take $L'' = 45°$; $\sin.^2 L'' = \frac{1}{2}$; then $g'' = g\left(1 + 3\,\frac{\alpha}{2}\right)$; and this degree multiplied by 90 will give the value of a quarter of the meridian. From theſe equations it appears that the increaſe of the degree from the equator to the poles is very nearly proportional to the ſquares of the ſine of the latitude.

If the degree meaſured in Peru be employed with that meaſured in France by Mechain and Delambre in the above formulæ, the compreſſion α will be $\frac{1}{334}$ and $b' = 1 - \frac{333}{334}$ and $1 - b'^2 = e^2$.

Therefore $e^2 = 1 - \left(\frac{333}{334}\right)^2 = 0.005979058$, which quantity has for its log. 7.7766329.

The equatorial degree is here ſuppoſed = 51077.7 = 56753 (Toiſes. Decim. Sexag.)
And the degree at 45° = 51307.4 = 57008

For the equation $\alpha = \frac{g'' - g}{3\,g \sin.^2 L''}$ gives $g'' = g\,(1 + 3\,\alpha \sin.^2 L'')$ and when $L'' = 45°$ $\sin.^2 L'' = \frac{1}{2}$ $\therefore g'' = 51307.4$ decimal = 57008 toiſes ſexageſimal.

From equat. (14), if $Q = 10000000$ metres; $a = \frac{10000000}{\frac{1}{2}\pi}\left(1 + \frac{1}{4}e^2 + \frac{7}{64}e^4 + \frac{15}{256}e^6\right)$, and ſince $e^2 = 2\,\alpha - \alpha^2$, it follows that a expreſſed in metres

$$a = \frac{10000000}{\frac{1}{2}\pi}\left(1 + \frac{1}{2}\alpha + \frac{3}{16}\alpha^2 + \frac{1}{32}\alpha^3\right)$$ from which log. $a = 6.8045305$, &c. &c.

If with the value of the degree at the equator we deduce its radius of curvature R, we may, by ſubſtituting its value in equation (12), find the equatorial ſemidiameter, a, as likewiſe b. With the above data theſe appear to be

a = 32271226	toiſes	Log.	6.5147105
= 6375737	metres	Log.	6.8045304
= 20918230	Engliſh feet	Log.	7.3205255
b = 3261432	toiſes	Log.	6.5134083
= 6356649	metres	Log.	6.8032283
= 20855922	Engliſh feet	Log.	7.3192234

If

If in the expreſſion $\alpha = \frac{g'-g}{3g \text{ fin.}^2 L}$ we take $g' = 60820$ fathoms for the lat. 52° 2′ 20″, as found by the meaſurement of the arc between Clifton and Dunnoſe, the ellipticity, α, will be found $= \frac{1}{336.5}$

For $60820 - 60484.8 = 335.2 = g' - g$

$$\text{Log. } \frac{335.2}{3 \times 60484.8 \text{ fin.}^2 52.2.20} = 7.4730119 = \frac{1}{336\,5.}$$

Method of M. Legendre for calculating the Latitude, Longitude, and Azimuths of the Stations on a Meridian Line.

Let P (*fig.* 65.) be the pole of the earth, P A, P B two elliptic meridians, let L be the known latitude of the point A, it is required to find that of the point B, ſituated on the arc B A, perpendicular to P A, its longitude, and the azimuth of A as ſeen from B.

Suppoſe A M, B N to be verticals to the points A and B; make A B$=y$, M A$=r$, N B$=r'$.

The ſmall arc y, having r for its radius of curvature, it follows that a ſimilar arc φ, whoſe radius $=1$, will have for its value $\frac{y}{r}$.

If from the point M as a centre, and with the radius M $b=1$, the arcs $a\,b$, $a\,p$, $p\,b$, be deſcribed, a ſpherical triangle will be formed, in which the ſide $p\,a = 90° - L$ will be known, as alſo the ſide $a\,b = \varphi$, and the contained right angle $p\,a\,b$; then by trigonometry,

$$\text{cof. } (p\,b) = \text{fin. L cof. } \varphi,$$

$$\text{tang. P} = \frac{\text{tang. } \varphi}{\text{cof. L}}$$

$$\text{tang. } b = \frac{\text{cof. L}}{\text{fin. } \varphi}$$

$$p\,b = 90° - L + \tfrac{1}{2}\varphi^2 \text{ tang. L}$$

$$P = \frac{\varphi}{\text{cof. L}} - \tfrac{1}{3}\varphi^3 \frac{\text{fin.}^2 L}{\text{cof.}^3 L},$$

$$b = 90° - \varphi \text{ tang. L} + \tfrac{1}{3}\varphi^3 \text{ tang. L } (\tfrac{1}{2} + \text{tang.}^2 \text{L}).$$

From the value $p\,b$ may be deduced the approximate value of the latitude B.

$$90° - p\,b = L - \tfrac{1}{2}\varphi^2 \text{ tang. L.}$$

The angle P is the difference of longitude between A and B, and the angle b the required azimuth P B A.

To have more exactly the latitude of the point B, it may be remarked that it is equal to the complement of the angle P N B, or of the angle P M B + N B M $= p\,b +$ N B M. But as the angle N A M is very nearly equal to the angle N B M, we ſhall have N B M $= \frac{\text{M N cof. L}}{r} = \downarrow$.

M N may be obtained by the formula (8), for if we take $n' = r$, then C M$=e^2 r$ fin. L, in the ſame manner for the point B, whoſe latitude is L′ − C N$=e^2 r$ fin. L′; thus very nearly we have

$$\text{M N} = e^2 r \text{ (fin. L} - \text{fin. L}').$$

It is eaſy to ſee that this value is always poſitive, that is to ſay, C M $>$ C N, for the latitude of A being evidently greater than that of B, the ſine of L is greater than L′. To decompoſe into factors the quantity fin. L − fin. L′, we may take the trigonometrical formula.

Sin. L − ſin. L′ $= 2$ fin. $\left(\frac{L-L'}{2}\right)$ cof. $\left(\frac{L+L'}{2}\right)$; hence

$$\text{M N} = 2e^2 r \text{ fin.} \left(\frac{L-L'}{2}\right) \text{ cof.} \left(\frac{L+L'}{2}\right),$$

Upon the ſuppoſition that L − L′ is very ſmall, the arc may be taken for its ſine, and cof. L for cof. $\left(\frac{L-L'}{2}\right)$; then M N$=e^2 r$ (L − L′) cof. L.

But the approximate latitude of B or L′ $=$ L $-\frac{1}{2}\varphi^2$ tang. L; hence M N$=\frac{1}{2}e^2 r \varphi^2$ tang. L cof. L$=\frac{1}{2}e^2 r \varphi^2$ ſin. L.

It may be deſirable to have a more exact expreſſion for M N and $\downarrow$, which may be obtained thus: ſince $r = \frac{1}{(1 - e^2 \text{ fin.}^2 L)}$; r may be taken without ſenſible error $= 1$; then calling L − L′$=d$L, L + L′$=2$L $-d$L, and the equation M N$=2e^2 r$ fin. $\frac{L-L'}{2}$ cof. $\frac{L+L'}{2}$ will become M N$=2e^2$ fin. $\frac{1}{2}d$L cof. (L $-\frac{1}{2}d$L).

Expanding the factor cof. $-d$L being ſuppoſed very ſmall, M N$=2e^2$ fin. dL cof. L$+\frac{1}{2}e^2$ fin.^{2} dL fin. L.

But when the arc A is very ſmall, fin. A$=2$ fin. $\left(\frac{A}{2}\right)$, and M N$=e^2$ fin. dL cof. L$+\frac{1}{2}e^2$ fin. dL, cof. L.

Since fin. N B M$=$ fin. $\downarrow = \frac{\text{M N fin. B N M}}{\text{M B}} = \frac{\text{M N cof. L}'}{r}$, we ſhall have from the preceding values of M N and r', fin. $\downarrow = e^2$ fin. dL cof. L cof. L′$+\frac{1}{2}e^2$ fin.^{2} dL fin. L cof. L′.

But cof. L′$=$cof. L$+$ſin. L fin. dL;

Hence $\downarrow = e^2 d$L cof.^{2} L$+\frac{3}{2}e^2 d$L fin. dL fin. L cof. L.

Hence it follows that the angle N B M$=\frac{1}{2}\varphi^2 e^2$ fin. L cof. L, and conſequently the true latitude of B$=90° -$ $(p\,b) - \downarrow$, or L′$=$L$-\frac{1}{2}\varphi^2$ tang. L$-\frac{1}{2}e^2 \varphi^2$ fin. L cof. L.

If L be the latitude of the point A, L′ the latitude of B, y the perpendicular diſtance of B from the meridian of A, and r the radius of the earth, or normal of the point A; taking R″ to expreſs the number of ſeconds in this radius, we ſhall obtain the following equations:

$$L' = L - \tfrac{1}{2}R''\left(\frac{y^2}{r^2}\right)\text{tang. L} - \tfrac{1}{2}R'' e^2 \left(\frac{y^2}{r^2}\right) \text{ fin. L cof. L } (a).$$

reciprocally $L = L' + \frac{1}{2}R\left(\frac{y^2}{r^2}\right)$ tang. L$-\frac{1}{2}$R″ $e^2\left(\frac{y^2}{r^2}\right)$ fin. L′ cof. L′. (b).

It is evident that e repreſenting the eccentricity, the ſecond term, in moſt caſes may be rejected. The difference of longitude of A and B $=$ P $= \frac{R''y}{r \text{ cof. L}}\left(1 - \frac{1}{3}\frac{y^2}{r^2}\text{ tang.}^2 \text{L}\right)$. ($c$).

And the azimuth of the arc B A or angle P B A$= z' =$ $90° - \frac{R''y}{r}$ tang. L$+\frac{1}{3}$R″ $\frac{y^3}{r^3}$ tang L $(\frac{1}{2} +$ tang.^{2} L). (d).

If L′ be only known, the laſt equation may, by a trigonometrical formula, be changed into $z' = 90° - R''\frac{y}{r}$ tang. L′ $-\frac{1}{3}R\frac{y^3}{r'^3}$ tang. L′ $(1 + \frac{1}{2}$ tang.^{2} L′). (e).

Theſe formulæ are not difficult in their application, and do not require a great many logarithms, as they have many elements in common, as will be ſeen in the examples.

It

It will ſometimes happen that the latitude of A is not directly given, but the diſtance x, of the perpendicular from the principal ſtation is known, and may be converted into degrees, by taking the radius of curvature of its middle point, recurring to the general expreſſion $\varphi = \frac{x\,R''}{\text{rad. of curv.}}$.

This method, which ſuppoſes the latitude of A known by approximation, is exact enough for every poſſible practical purpoſe.

The following expreſſion is ſtill more accurate; let l = latitude of the known ſtation.

L = latitude required of a point on the ſame meridian, then

$$L = l + \left(\frac{d\,l}{d\,x}\right)x + \tfrac{1}{2}\left(\frac{d^2\,l}{d\,x^2}\right)x^2 + ,$$

which will hereafter be ſhewn to be equal to $\frac{R''x}{r} - \frac{3}{4}R'' \left(\frac{e^2}{1-e^2}\right)$ ſin. $2L\,\frac{x^2}{r\,r}$:

r'' being = normal.
r = radius of curvature to the latitude l.

And if the value of $\varphi = \frac{y\,R''}{r}$ be known at any central point as a principal ſtation, its value at any diſtance x from that ſtation is equal $\varphi = R''\frac{y}{r}\left(1 - \frac{1}{2}\frac{r''^2}{\rho^2}e^2 \text{ ſin. } 2l\frac{x}{r}\right)$.

Example I.

Let B (*Pl.* VII. *fig.* 66.) be the tower of Dunkirk, A A′ the meridian of Greenwich; let the latitude of A be ſuppoſed 51° 3′ 37″. Let A A′ = x = 152550 Log. = 5.1834122

Tang. $\frac{P}{2} = 1^\circ\ 11'\ 22'' = 8.3172839$
$1 + e^2 \text{ cof.}^2 L$ - - 0.0010194

3in $L - L' = 87''.16 = 6.6258384$

The method of M. Delambre is quite independent of the diſtances from the perpendicular and meridian; inſtead of conſidering the diſtance of two points, as meaſured on a great circle paſſing through their verticals, he takes in preference the chords of the arcs.

The obſerved angles are reduced to thoſe of the chords; the baſe muſt likewiſe be reduced to a chord, if the utmoſt preciſion is required.

If B be the length of an arc, its exceſs above its chord Σ is thus found, ρ being the radius of the earth, $\Sigma' = \frac{1}{24}\frac{B^3}{\rho^2}$.

In this method, there is no occaſion for a figure, and the diſtance between the parallels may be found without calculating the diſtances to the meridian. There is one inconvenience which, as the author obſerves himſelf, is not inconſiderable, that the latitudes of the ſtations muſt be calculated previouſly to the diſtance between the parallels: but, as the latitudes of the ſtations are generally required, this cannot be conſidered as a ſerious objection.

Let us ſuppoſe at firſt the earth to be ſpherical, and the triangle P A B to be no longer rectangular. Then,
Cof. P B = cof. A ſin. P A ſin. A B + cof. P A cof. A B; and agreeable to the above notation,

Sin. $L' = \text{cof. A cof. L. ſin } \varphi + \text{ſin. L cof. } \varphi$:

Hence, ſin. L − ſin. L′ = ſin. L − ſin. L cof. φ − ſin. φ cof. A cof. L
$= (1 - \text{cof. } \varphi) \text{ ſin. L} - \text{ſin. } \varphi \text{ cof. A cof. L}$
$= 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ ſin. L} - \text{ſin. } \varphi \text{ cof. A cof. L.}$

But if A be taken exteriorly, that is, if, inſtead of the cof. A, we ſubſtitute its value taken from the equation A = 180° − Z − cof. A = cof. Z:
then, ſin. L. − ſin. L′ = ſin. φ cof. Z. cof. L + 2 ſin.$^2 \frac{1}{2}\varphi$ ſin. L:

$$\text{or, } 2 \text{ ſin. } \tfrac{1}{2}(L - L') = \frac{\text{ſin. } \varphi \text{ cof. Z cof. L} + 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ ſin. L}}{\text{cof. } \frac{1}{2}(L - L')}:$$

conſequently,

$$2 \text{ ſin. } \tfrac{1}{2} d\,L = \frac{\text{ſin. } \varphi \text{ cof. Z cof. L} + 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ ſin. L}}{\text{cof. } (L - \frac{1}{2} d\,L}$$

$$= \frac{\text{ſin. } \varphi \text{ cof. Z cof. L} + 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ ſin. L}}{\text{cof. } \frac{1}{2} d\,L \text{ (cof. L} + \text{ſin. L tang } \frac{1}{2} d\,L)}.$$

Now, very nearly 2 ſin. $\frac{1}{2} d\,L = \text{ſin. } d\,L$, and cof. $\frac{1}{2} d\,L = 1$; hence dividing by the cof. L ſin. $d\,L =$ $\frac{\text{ſin. } \varphi \text{ cof. Z} + 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ tang. L}}{1 + \text{tang. L tang. } \frac{1}{2} d\,L}$: this expanded by the binomial formula

ſin. $d\,L = (\text{ſin. } \varphi \text{ cof. Z} + 2 \text{ ſin.}^2 \frac{1}{2}\varphi \text{ tang. L})(1 - \text{tang. L tang. } \frac{1}{2} d\,L \ldots.)$

Since $d\,L$ is very ſmall, the tang. $d\,L$ may, without ſenſible error, be taken = ſin. $\frac{1}{2} d\,L = \frac{1}{2}$ ſin. $d\,L$: then the preceding formula becomes

tang. $\frac{1}{2} d\,L = (\frac{1}{2} \text{ſin. } \varphi \text{ cof. Z} + \text{ſin.}^2 \frac{1}{2}\varphi \text{ tang. L})(1 - \text{tang. L tang. } \frac{1}{2} d\,L + \text{tang.}^2 \text{L tang.}^2 \frac{1}{2} d\,L)$. (1).

Multiplying and rejecting the terms of the third order,

tang. $\frac{1}{2} d\,L = \frac{1}{2}$ ſin. φ cof. Z + ſin.$^2 \frac{1}{2}\varphi$ tang. L − $\frac{1}{2}$ ſin. φ cof. Z tang. $\frac{1}{2} d\,L$ tang. L ....)

Subſtitute for tang. $\frac{1}{2} d\,L$ its approximate value $\frac{1}{2}$ ſin. φ cof. Z: then,

tang. $\frac{1}{2} d\,L = \frac{1}{2}$ ſin. φ cof. Z + ſin.$^2 \frac{1}{2}\varphi$ tang. L − $\frac{1}{4}$ ſin.$^2 \varphi$ cof.^{2} Z tang. L.

But ſince cof. 2 Z = 1 − ſin.^{2} Z;

Tang. $\frac{1}{2} d\,L = \frac{1}{2}$ ſin. φ cof. Z + ſin.$^2 \frac{1}{2}\varphi$ tang. L − $\frac{1}{4}$ ſin.^{2} φ tang. L − $\frac{1}{4}$ ſin.$^2 \varphi$ cof.^{2} Z tang. L.

But $\frac{1}{4}$ ſin.$^2 \varphi =$ ſin.$^2 \frac{1}{2}\varphi$, nearly: hence,

Tang. $d\,L = \frac{1}{2}$ ſin. φ cof. Z. + $\frac{1}{4}$ ſin.$^2 \varphi$ ſin.^{2} Z tang. L; (2)

hence, tang. $d\,L$ or $d\,L = \text{ſin. } \varphi \text{ cof. Z} + \frac{1}{2}\text{ſin.}^2 \varphi \text{ ſin.}^2 \text{Z tang. L}$
$= \varphi \text{ cof. Z} + \frac{1}{2}\varphi \text{ ſin. } \varphi \text{ ſin.}^2 \text{Z tang. L.}$

$d\,L$ expreſſes the difference of the parallels paſſing through the two extremities of the arc φ; for a more exact value, we may in the expanſion of equation (1) preſerve the terms of tang.^{2} L. We ſhall find ſin. $d\,L = \text{ſin. } \varphi \text{ cof. Z} + \frac{1}{2}$ ſin.$^2 \varphi$ ſin.^{2} Z tang. L $- \frac{1}{2}$ ſin.$^3 \varphi$ cof. Z − ſin.^{2} Z tang.^{2} L.

But by the reſolution of the triangles, the chord of φ is given: ſo that,

ſin. $d\,L = \text{K cof. } \frac{1}{2}\varphi \text{ cof. Z } (1 + \text{tang. } \frac{1}{2}\varphi \text{ ſin. Z tang. Z tang. L} - 2 \text{ ſin. } \frac{1}{2}\varphi \text{ ſin.}^2 \text{Z tang.}^2 \text{L}).$

This is the value of ſin. $d\,L$ expreſſed in terms of the ſame meaſure as the chord K: for to have $d\,L$ itſelf, to this expreſſion muſt be added the exceſs of the arc above the ſign, or,

$$\tfrac{1}{6} \text{ſin.}^3 d\,L = \tfrac{1}{6}\left(\frac{(\text{K cof. } \frac{1}{2}\varphi \text{ cof. Z})^3}{\rho^2}\right);$$

ρ being the radius of the earth in toiſes, fathoms, or metres.

Alſo $\frac{1}{6}$ fin.^{3} d L $=$ $\frac{3}{2}$ (K fin.^{2} $\frac{1}{2}\varphi$ cof.^{2} $\frac{1}{2}\varphi$ cof.^{3} Z).
Hence,
d L $=$ K cof. $\frac{1}{2}\varphi$ cof. Z (1 + tang. $\frac{1}{2}\varphi$ fin. Z tang. Z tang. L $-$ 2 fin. $\frac{1}{2}\varphi$ tang. $\frac{1}{2}\varphi$ fin.^{2} Z tang.^{2} L $+$ $\frac{2}{3}$ fin.^{2} $\frac{1}{2}\varphi$ cof.^{2} Z).

And finally,
L$'$ $=$ L $-$ d L $=$ L $-$ (φ cof. Z $+$ $\frac{1}{2}\varphi$ fin. φ fin.^{2} Z tang. L)
Such is the approximate value of the latitude of the point B. Now to take into conſideration the eccentricity, we muſt recollect that the exact latitude of B $=$ 90° $-$ P C B; but ſince PCB $=$ PMB $-$ NBM, and PMP $=$ 90° $-$ L$'$ $-$ (L $-$ d L), it follows that the exact latitude B $=$ L $-$ d L $-$ $\downarrow$.

Subſtitute for d L its value found above, and for $\downarrow$ its value as alſo above determined.

Then denoting the exact latitude by L$'$, we ſhall have L$'$ $=$ L $-$ (φ cof. Z $+$ $\frac{1}{2}\varphi$ fin. φ fin.^{2} Z tang. L) (1 $+$ e^2 cof.^{2} L $+$ $\frac{3}{2}$ e^2 fin. d L fin. L cof. L).

In this formula the term $\frac{3}{2}$ e', &c. may be neglected; then the factor of d L will be reduced to (1 $+$ e^2 cof.^{2} L). As to the quantity φ, it ſhould be expreſſed in ſeconds, and it has already been ſhewn that if K repreſent the chord of an arc, φ will be equal to $\frac{\text{K R}''}{\text{normal}}$.

Proceeding to find the azimuth Z$'$, or that of the point A on the horizon of B, the triangle P A B gives this equation:

$$\text{Tang. } \tfrac{1}{2}(\text{B} + \text{A}) = \frac{\text{cot. } \frac{1}{2}\text{P cof. } \frac{1}{2}(\text{P B} - \text{P A})}{\text{cof. } \frac{1}{2}(\text{P B} + \text{P A})} = \frac{\text{cot. } \frac{1}{2}\text{P cof. } \frac{1}{2}(\text{L} - \text{L}')}{\text{cof. } (180° - (\text{L} + \text{L}'))} = \frac{\text{cot. } \frac{1}{2}\text{ P cof. } \frac{1}{2}(\text{L} - \text{L}')}{\text{fin. } \frac{1}{2}(\text{L} + \text{L}')}$$

and ſince cot. $= \frac{1}{\text{tang.}}$.

Cot. $\frac{1}{2}$(B + A) $=$ tang. (90° $-$ $\frac{1}{2}$(B + A)) $=$ $\frac{\text{tang. } \frac{1}{2}\text{P fin. } \frac{1}{2}(\text{L} + \text{L}')}{\text{cof. } \frac{1}{2}\text{ L} - \text{L}}$.

As 90° $-$ $\frac{1}{2}$(B + A) and P are always very ſmall angles:

$$90° - \tfrac{1}{2}(\text{B} + \text{A}) = \frac{\frac{1}{2}\text{P fin. } \frac{1}{2}(\text{L} + \text{L}')}{\text{cof. } \frac{1}{2}(\text{L} - \text{L})}:$$

$$\text{and, B} = (180 - \text{A}) - \frac{\text{P fin. } \frac{1}{2}(\text{L} + \text{L}')}{\text{cof } \frac{1}{2}(\text{L} - \text{L}')} = \text{Z} - \frac{\text{P fin. } \frac{1}{2}(\text{L} + \text{L}')}{\text{col. } \frac{1}{2}(\text{L} - \text{L}')}.$$

This formula gives the direction B A reckoned north; if it be ſouth of the weſt, we muſt add 180°, and then,

$$\text{Z}' = 180° + \text{Z} - \frac{\text{P fin. } \frac{1}{2}(\text{L}' + \text{L})}{\text{cof. } \frac{1}{2}(\text{L} - \text{L}')}.$$

The ſame triangle gives,

$$\text{fin. P} = \frac{\text{fin. A B fin. A}}{\text{cof. L}'} = \frac{\text{fin. } \varphi \text{ fin. Z}}{\text{cof. L}} \quad (3).$$

From whence may be deduced,

$$\text{Z}' = 180° + \text{Z} - \frac{\text{fin. } \varphi \text{ fin Z fin } \frac{1}{2}\text{L} + \text{L}'}{\text{cof. } \frac{1}{2}(\text{L} - \text{L}') \text{ cof. L}'}$$

$$= 180° + \text{Z} - \frac{\varphi \text{ fin. Z } \frac{1}{2}(2\text{L}' + d\text{ L})}{\text{cof. L}' \text{ cof. } \frac{1}{2} d\text{ L}}$$

$$= 180° + \text{Z} - \frac{\varphi \text{ fin. Z}}{\text{cof. } \frac{1}{2} d\text{L}} \left(\frac{\text{fin. L}' \text{cof. } \frac{1}{2} d\text{L} + \text{fin. } \frac{1}{2} d\text{L cof. L}'}{\text{cof. L}'} \right)$$

$$= 180° + \text{Z} - \varphi \text{ fin. Z tang. L}' - \varphi \text{ fin. Z tang. } \tfrac{1}{2} d\text{ L}:$$

for d L ſubſtitute its value (2), we ſhall have (rejecting the terms of the third order) ſince 2 fin. Z cof. Z $=$ fin. 2 Z,
Z$'$ $=$ 180 $+$ Z $-$ φ fin. Z tang. L$'$ $-$ $\frac{1}{4}$ φ fin. φ fin. 2 Z.

This is the azimuth of A, ſeen on the horizon of B, to which there is nothing to add for the ellipticity of the earth, the effect of which is inſenſible.

As to the longitude M$'$ of the point B, it is clear that it reſults from equation (3); for if M $=$ longitude of A; P $=$ M$'$ $-$ M.

And fin. P, or fin. (M$'$ $-$ M) $=$ $\frac{\text{fin. } \varphi \text{ fin. Z}}{\text{cof. L}'}$,

or nearly exact M$'$ $=$ M $+$ $\frac{\varphi \text{ fin. Z}}{\text{cof. L}'}$.

If in this expreſſion for L$'$ we ſubſtitute its approximate value L $-$ φ cof. Z

$$\text{M}' = \text{M} + \frac{\varphi \text{ fin. Z}}{\text{cof. (L} - \varphi \text{ cof. Z)}}.$$

Expanding the denominator, and conſidering φ cof. Z as a ſmall arc,

$$\text{M}' = \text{M} + \frac{\varphi \text{ fin Z}}{\text{cof. L (1} + \varphi \text{ cof. Z tang. L}} = \text{M} + \frac{\varphi \text{ fin Z}}{\text{cof. L}} (1 - \varphi \text{ cof. Z tang. L}).$$

And, finally, M$'$ $=$ M $+$ $\frac{\varphi \text{ fin. Z}}{\text{cof. L}}$ $-$ $\frac{1}{2}\varphi^2$ fin. 2 Z $\frac{\text{tang. L}}{\text{cof. L}}$.

To recapitulate the preceding reſults;
let ρ $=$ radius of the equator,
e $=$ eccentricity,
φ $=$ the arc expreſſed in ſeconds, correſponding with the chord K of a terreſtrial arc, which is one ſide of the triangle,
L $=$ the latitude known of one extremity of the chord K,
L$'$ $=$ the latitude ſought of the other,
M $=$ the longitude known, } reckoned from the ſouth to
M$'$ $=$ the longitude ſought, } the weſt, from 0 to 360,
Z $=$ the azimuth known, }
Z$'$ $=$ the azimuth ſought, } reckoned the ſame.

$$\varphi = \frac{\text{K}}{\rho \text{ fin. } 1''} (1 - \tfrac{1}{2} e^2 \text{ fin.}^2 \text{ L}). \quad (a)$$

$$\text{L}' = \text{L} - (\varphi \text{ cof. Z} + \tfrac{1}{2} \varphi \text{ fin. } \varphi \text{ fin.}^2 \text{ Z tang. L}) (1 + e^2 \text{ cof.}^2 \text{ L}). \quad (b)$$

$$\text{Z}' = 180 + \text{Z} - \varphi \text{ fin. Z tang. L}' - \tfrac{1}{4} \varphi \text{ fin. } \varphi \text{ fin. 2 Z}. \quad (c)$$

$$\text{M}' = \text{M} + \varphi \frac{\text{fin. Z}}{\text{cof. L}'} = \text{M} + \frac{\varphi \text{ fin. Z}}{\text{cof. Z}} - \tfrac{1}{2}\varphi^2 \text{fin.}^2 \text{Z} \frac{\text{tang. L}}{\text{col. L}}. \quad (d)$$

d L, or difference of the parallels in terms of the ſtandard meaſure, as toiſes, fathoms, or metres.

d L $=$ (K cof. $\frac{1}{2}\varphi$ cof. Z) $+$ (K cof. $\frac{1}{2}\varphi$ cof. Z) (tang. $\frac{1}{2}\varphi$ fin. Z tang. Z tang. L) $-$ 2 (K cof. $\frac{1}{2}\varphi$ cof. Z) (fin. $\frac{1}{2}\varphi$ tang. $\frac{1}{2}\varphi$ fin.^{2} L tang.^{2} L) $+$
$\frac{\text{(ſum of the three firſt terms)}^3 (1 - e^2 \text{ fin. L})}{6\rho^2}$.

The fourth term of this expreſſion is the exceſs of the arc above the ſine, or $\frac{1}{6}$ $\frac{\text{fin.}^3 d\text{ L}}{r^3}$; here the radius r is that of the earth ſuppoſed ſpherical, if for greater exactneſs we employ the radius of curvature of the arc A B, or $r = \frac{\rho}{(1 - e^2 \text{ fin.}^2 \text{ L})^{\frac{1}{2}}}$, and inſtead of d L, its value found as above, we ſhall have the term in queſtion.

Example I.

Let the latitude of A be equal 48° 50′ 49″.7; log. of AB (79095.6 feet) $=$ 4.8981525 $=$ K; Z the azimuth of AB, or angle A $=$ 13° 3′ 27″, required the latitude of B?

$$\varphi = \frac{\text{K R}''}{\rho} (1 - \tfrac{1}{2} e^2 \text{ fin. }^2\text{L}) \text{ or } = \frac{\text{K R}''}{\rho (1 + e^2 \text{ fin. }^2\text{L.})}$$

Sine 1″	-	4.6855749
Sin.² Z	-	9.9913940
Tang. L′	-	0.0875019
Log. 0.5	-	9.6989700
Cor.	32″.44	1.5111102

467″.93 − 32″.44 = 435″.49 = 2.6389782
e^2 col.² L - - 7.3845326

Cor. - 1″.105 = 0.0235108

Difference of latitude = 435″.49 + 1″.10 = 436.6.

To find Z′ or azimuth of Dunnose, as seen from Beachy-head.

$Z' = 180 + Z\ \varphi$ fin. Z. tang. L $- \frac{1}{3}\varphi$ fin. φ, fin.² Z.

φ	3.5238228	Log. $\frac{1}{4}$	9.39794
Sin. Z	9.9956970	φ^2 -	7.04764
Tang. L′	0.0876046	Sin. 1″	4.68557
		Sin.² Z	9.44351
4046.9	= 3.6071244		0.57466
		− 3″.75	

4046″.9 − 3.7 = 4043″.2 = 1° 7′ 23″.2.

If Z = 98° 3′ 7″, − Z′ = 96° 55′ 43″.8, which is 14″.2 less than the observed azimuth. See Trigon. Survey.

If we suppose the observed azimuth to be correct, namely, 96° 55′ 58″, it would follow, that we have made an erroneous supposition of the value of the normal. The above formula should correct this error, and give the true value.

For φ fin. Z, tang. L′ is equal to 4032.7 instead of 4046.9; hence log. φ = 3.5222943.

But $\varphi \frac{R'' K}{\text{normal}}$ ∴ normal = $\frac{K R''}{\varphi}$

K	-	= 5.5307092
R″	-	= 5.3144251
Co. log. φ		= 6.4777057
Log. n	-	= 7.3228400
$\frac{R''}{3600}$	-	= 1.7581226

Feet. Fathoms.
5.5647174 = 367043 = 61174 = the length of a degree perpendicular to the meridian.

A difference of 5″ in the value of Z′ will produce an error of 47 fathoms in the length of the perpendicular degree.

Example V.

Given AB = K = 140580.4.
Z = 20° 58′ 39″.
L = 50 37 8 = Lat. of A.

Required the distance between the parallels of A and B, Dunnose and Butser-hill.

Log. K = 5.1479235

Theſe formulæ, though only approximative, are, nevertheleſs, capable of extreme accuracy. They are, in fact, both identical, only differing in their mode of application. They both imply the reſolution of two right-angled ſpheroidical triangles. In the firſt method, the triangle A A′ B (*fig.* 66.) is ſuppoſed previouſly reſolved; and the formula only relates to the ſecondary triangle B′ A′ B, in which the ſide A′ B′ is found ſubject to a certain correction, ariſing from having computed it with too long a radius; and, therefore, it has been made a part of too large a ſphere, and, of courſe, its proportionate part in minutes or ſeconds too ſmall; its correction is ($e^2\, d$ L, cof.^{2} L $+ \frac{3}{2}\, e^2\, d$ L, ſin. d L); but in ſo ſmall an arc as A′ B′, the firſt term is quite ſufficient. In the ſecond method, we reſolve each triangle ſeparately, and find the arcs A A′ and A′ B′, each ſubject to the error above-mentioned, which may be very conſiderable in the firſt triangle, if it be of great extent; and, therefore, the ſecond part of the correction (for which we have calculated Table IX.) ſhould be applied.

The following example ſhews the analogy between the two formulæ.

1ſt Cor.	1226.5	= A A′		1ſt Cor.	1223″.64	= A A′
2d Cor.	26.89	= A′B′		2d Cor.	2.87	
3d Cor.	0.06			3d Cor.	26.89	= A′ B′
				4th Cor.	0.06	
	1253.45	= 20′ 53″.45			1253″.46	= 20′ 53″.46

Uſe of the Formula.

$$R'' \frac{x}{r} - \tfrac{1}{4} R'' \left(\frac{e^2}{1-e^2}\right) \text{ſin. } 2l \frac{x^2}{rn} = l - L'.$$

If, in the above example, we wiſh to find the value A A′ by the above formula, it is eaſy to compute it for one central ſituation, as Greenwich. The following rule will be the reſult. To the log. of the number of feet in

A A′ - - - - -	=	5.0945480
Add. conſtant. log. $\left(\frac{R''}{r}\right)$ -	=	7.9941110
Which gives Part I. = 1226″.47	=	3.0886590
To double the log. x -	=	0.1890960
Add. conſt. log. - -	=	8.3158923
Which gives Part II. = + 0.032	=	8.5049883

If A′ is ſouth, Part II. is additive.

A′ is north, Part II. is ſubtractive.

In this caſe, A A′ = 1226.47 + 0.03 = 1226.5, as found above in the laſt example. This method, though founded on a complex formula, is very eaſy and convenient in practice. The conſtant log. is thus found:

Log. $\frac{3}{4}$ - - -	=	9.8750612
$\frac{e^2}{1-e^2}$ - - -	=	7.7792374
R″ - - -	=	5.3144251
Co.-log. n - -	=	2.6786810
Co.-log. r - -	=	2.6796860
$l = 51° 28' 40'' = \text{Sin. } 2l$	=	9.9888016
		8.3158923

If the radius of curvature be required to an arc making an angle V′ with the meridian, it may be found thus:

Rad. of curv. $R = \frac{r+n}{2} - \frac{n-r}{2}$ cof. 2 V′, r being the rad. of curvature to the meridian, and n the normal; or, more exactly,

$$R = \frac{m\frac{r+n}{2} + \frac{n-r}{2} \text{ cof. } 2V'}{(r+n)^2}$$

V′ being the angle which the required arc makes with the perpendicular to the meridian.

In the uſe of theſe formulæ, it ſhould be obſerved, that in the above examples we have taken the elements for calculation, ſuch as are derived from the admiſſion of one hypotheſis applied to every portion of the globe. But from the various anomalies that have occurred in the courſe of the great trigonometrical ſurveys above related, it appears that this hypotheſis muſt be modified, if we wiſh to adapt our calculations to partial ſurveys. For we have ſeen in the preceding examples, that to reduce the ſides of the triangles, as given in linear meaſure, to an expreſſion in terms of the arc, it is neceſſary to know preciſel the radius of curvature to which each reſpective arc ſhould be adapted. Upon the ſuppoſition then of the earth being of ſome irregular figure, or that certain irregularities in the denſity of its ſtrata produce the ſame effect, by the deflection of the plumb-line, from the poſition it would otherwiſe aſſume; in either caſe, we may apply the formulæ above demonſtrated to practice, by chooſing ſuch an ellipſoid, as ſeems beſt adapted to the particular country on which the ſurvey is performed. It is upon this oſculatory ellipſoid that our calculations muſt be made, if we wiſh to determine the true latitudes and longitudes of places, as will moſt probably agree with accurate aſtronomical obſervation.

Thus, in the trigonometrical ſurvey, we find that by meaſuring an arc perpendicular to the meridian, the poſitions of ſeveral points were determined in a great meaſure independent of any hypotheſis. And this is the more neceſſary when a meredian line is interrupted, as is the caſe between Dunkirk and Dunnoſe, when we wiſh to conſider the meridian as meaſured in England as a continuation of that meaſured in France. In ſecondary ſurveys, where the triangles are ſmall, much of the labour of the preceding calculations may be abridged by rejecting the terms of the formulæ that involve e^2, and thus reducing the whole to ſpherical computation; nor will it often be found neceſſary to calculate the ſpherical exceſs, particularly if attention be paid to Le Gendre's theorem. And indeed the knowledge of the ſpherical exceſs might be always diſpenſed with, if we had only to calculate the triangles of the ſtations: but the caſe is different with the triangles which are decompoſed by the meridian line which paſſes through them. In theſe partial triangles, one ſide and two angles are uſually given, from which the third angle is to be deduced by ſubtracting it from 180°; the angles thus determined will be erroneous, if this correction be neglected.

The computed latitudes and longitudes will be but little affected by the omiſſion; but the correction ſhould be attended to, when the difference between the parallels is required with great exactneſs.

But it is very doubtful, if any one hypotheſis can be extended to a conſiderable diſtance from the place of actual obſervation. In example IV. it may be ſeen in what manner the longitude of Dunnoſe was found relatively to Beachyhead, by azimuthal obſervations at each ſtation; and the other longitudes weſtward are computed on a ſuppoſition that a degree of a great circle perpendicular to the meridian continues of the ſame magnitude in a given latitude. But from example IX. and X. taken from the next great triangle weſtward, it appears highly probable that the value of the degree on the perpendicular ſuddenly diminiſhes, and that the ſame irregularities take place in that direction, as have been obſerved in proceeding to the north. From all theſe conſiderations it follows, that the latitudes and longitudes of places, as referring to certain aſtronomical poſitions, can no longer be conſidered as accurate expreſſions to deſignate the relative ſituations of places on the earth. We think therefore that it would be adviſable, in geographical ſurveys of large extent, that the relative latitudes and longitudes to ſome central point ſhould be calculated by the above formulæ or other equivalent methods, and that theſe ſhould be conſidered as

mean latitudes and longitudes. From a careful comparifon of thefe with the aftronomical pofitions obtained by other means, we may expect to derive a more accurate knowledge of the irregularities in the figure of the earth.

There are many individuals in this country, who poffefs inftruments capable of making geodetical obfervations fufficiently accurate to throw great light upon this curious fubject. The great furvey fhould ferve as a bafis. The obferver, by means of the known objects already determined, might afcertain the pofition of any other ftation, and calculate trigonometrically its diftance from the meridian, and perpendicular of Greenwich; he fhould then determine the latitude aftronomically, and compare it with that deduced from computation, according to the rules already explained. It was to facilitate obfervations of this kind, and to induce the poffeffors of fuch inftruments to employ them, that we have allotted fo large a fpace to this fubject.

The formulæ we have made ufe of in the foregoing examples were intended only for obferved triangles, but they may be applied without fenfible error to a triangle of very conficerable extent; but ftill it fhould be remembered, that the fuppofitions upon which they are founded are not ftrictly true, for the fides of thefe triangles are lines connecting two given points by the fhorteft diftance over the furface of a fpheroid, and are in fact curve lines of double curvature, except in the cafe of their coincidence with the meridian or equator, that is, their extreme elements are not in the fame plane. Thefe and other confiderations of a fimilar nature, have no fenfible influence on any practical rule, we fhall therefore not enter into them any farther at prefent, but refer them to FIGURE *of the Earth*, to which article they more properly belong.

It is of great importance, in a trigonometrical furvey, to know the relative heights of the ftation above the level of the fea: for this purpofe it is neceffary to obferve the apparent depreffion of one ftation as feen from the other. For the method of making this obfervation and applying the requifite corrections, fee DEPRESSION.

The Arguments to this Table are the Base and Height of a Triangle in Toises.

The Toise is to the Fathom as 76,736 to 72.000.

TABLES to facilitate the Calculation of Spheroidical Triangles.

In the above table, the ellipticity is ſuppoſed $\frac{1}{334}$, the degree at the equator, and at 45°, taken from actual meaſurement; and the other, degrees calculated according to the rules explained in the text.

TABLE of Perpendicular Degrees on the Spheroid calculated to every Degree of the Meridian in Engliſh Feet, (elliptcity $= \frac{1}{334}$.)

DEGREE *of Longitude.* See the preceding article and LONGITUDE.

DEGREE, in *Civil* and *Canon Law*, denotes an interval in cognation of kinſhip, whereby proximity and remoteneſs of blood are computed.

Degrees are the intervals whereby it is known what perſons are neareſt to the ſtock or root. Or they are the diſtances of one perſon from another in the line of conſanguinity or affinity, reckoned from ſome common parent or anceſtor. See CONSANGUINITY.

We ſay, the ſecond degree, the third degree; Gregory the Great was the firſt who prohibited marriage to the ſeventh degree; which reſtriction was long obſerved: the ſecond council of Lateran, under Innocent III. reſtrained the prohibition to the fourth degree incluſive, that is, to couſin Germans' children. See MARRIAGE.

In computing degrees of conſanguinity, the rule of the civil law is univerſal, either in the direct or collateral, otherwiſe called the oblique line: "Quot ſunt generationes tot ſunt gradus." Every generation in the direct line conſtitutes a different degree, reckoning either upwards or downwards; and this method of computation univerſally obtains, as well in the civil and canon, as in the common law. But in the canon law, the rule is different for the oblique line, and here a diſtinction is made between the equal and unequal oblique line.

In the firſt caſe the rule is, "Quot gradibus perſonæ cognatæ diſtant a communi ſtipiti, tot gradibus inter ſe diſtant." In the ſecond caſe, the rule is, "Quot gradibus perſona remotior diſtat a communi ſtipite tot gradibus perſonæ diſtant inter ſe." Or, generally, in whatſoever degree two perſons, or the moſt remote of them, are diſtant from the common anceſtor, that is the degree in which they are related to each other. Thus, Titius and his brother are related in the firſt degree, becauſe from the father to each of them is counted only one; Titius and his nephew are related in the ſecond degree; for the nephew is two degrees removed from the common anceſtor; *viz.* his own grandfather, the father of Titius. This rule of computation is adopted by our law; though the civilians count upwards from either of the perſons related to the common ſtock, and then downwards again to the other, reckoning a degree for each perſon both aſcending and deſcending. For the true reaſon of the different methods of computing the degrees of conſanguinity, in the civil law on the one hand, and in the canon and common laws on the other; ſee DESCENT.

DEGREES *of Compariſon*, in *Grammar*, are uſually reckoned three, *viz. poſitive, comparative*, and *ſuperlative;* which ſee reſpectively. The ingenious Mr. Harris, (Hermes, p. 197.) in tracing the riſe of compariſon, and its different degrees, obſerves, that they cannot be more than two; one to denote ſimple exceſs, and one to denote ſuperlative. If we were to introduce more degrees than theſe, we ought, he ſays, perhaps, to introduce infinite, which is abſurd. For why ſtop at a limited number, when in all ſubjects, ſuſceptible of intenſion, the intermediate exceſſes are in a manner infinite? There are infinite degrees of *more* white, between the firſt ſimple white, and the ſuperlative, *whiteſt;* the ſame may be ſaid of *more* great, *more* ſtrong, *more* minute, &c. He adds, the doctrine of grammarians about *three* ſuch degrees, which they call the poſitive, the comparative, and the ſuperlative, muſt needs be abſurd; both becauſe in their poſitive there is no compariſon at all, and becauſe their ſuperlative is a comparative, as much as their comparative itſelf; *e. g.* "Socrates was the *moſt wiſe* of all the Athenians." "Homer was the *moſt ſublime* of all poets." Theſe comparatives however, as well the ſimple as the ſuperlative, ſeem ſometimes to part with their relative nature, and only retain their intenſive. Thus, in the degree denoting ſimple exceſs,

"*Triſtior*, et lacrymis oculos ſuffuſa nitentes."
Virg.

In the ſuperlative degree this is more uſual, "Vir doctiſſimus;" Vir fortiſſimus," a moſt learned man, a moſt brave man; that is to ſay, not the *braveſt* and *moſt learned* man, that ever exiſted, but a man poſſeſſing thoſe qualities in an eminent degree. Comparative adverbs are retrenched by expreſſing their force in the primary attributive: thus, inſtead of *more fair*, grammarians ſay *fairer;* inſtead of *moſt fair, faireſt;* and the ſame holds true both in the Greek and Latin. But this practice has reached no farther than to adjectives, or, at leaſt, to participles, ſharing the nature of adjectives. As ſome attributives admit of compariſon, there are others which admit of none. Such, for example, are thoſe which denote that quality of bodies that ariſes from their figure, as when we ſay, a *circular* table, a *quadrangular* court, &c. the reaſon of which is, that a million of things participating the ſame figure, participate it *equally*, if they participate it at all. The ſame holds true in all attributives, denoting definitive quantities, whether continuous or diſcrete, whether abſolute or relative. Thus the *two-foot* rule A cannot be *more a two-foot* rule than any other of the ſame length, &c. &c. The reaſon of this is, that there can be no compariſon without intenſion and remiſſion; there can be no intenſion and remiſſion in things always definite. By the ſame reaſoning we perceive the cauſe, why no ſubſtantive is ſuſceptible of theſe comparative degrees. A mountain cannot be ſaid *more to be*, or to exiſt, than a mole-hill, but the *more* and *leſs* muſt be ſought for in their quantities.

DEGREES, in *Muſic*. This term has long been ſuperſeded by that of interval. The ſmall intervals, degrees, or intermediate ſteps from a given note to its 4th above, are three in number, the tone major, tone minor, and major ſemi-tone; as *c, d, e, f*.

Degrees or intervals leſs than concords are neceſſary in melody, as by theſe the concords are graduated, and their diſtance aſcertained. Des Cartes, who has been copied by our muſical lexicographer Graffineau, has rendered his definition of the term *degree* perplexing, and obſcure to ſtudents, by uſing, mathematically, his letters of reference, ſuppoſing A and B the diſtance of a major 3d; whereas, in muſical language, from A to B is but a major 2d. Then he talks of another ſound C put between A and B, which renders the paſſage wholly unintelligible. The following period from Des Cartes is clear and accurate. "It appears," ſays that author, "that degrees (in practical muſic) are the ſmall intervals, of which the concords or harmonical intervals are compoſed." See INTERVAL and CONCORD. "Muſical degrees are three: the major or greater tone, the leſs or minor tone, and the ſemitone."

The primary cauſe of the invention of ſmall degrees or intervals leſs than concords, and by which concords are divided, and as it were graduated, he judges to have been this, that there would be too great a diſproportion or inequality in their intenſeneſs, which would weary both the ſinger and the hearer.

Suppoſing A and C the diſtance of a third, if the voice were to proceed immediately, aſcending from A to C, then as C is the acuter ſound it ſtrikes the ear with more force than A; leſt the leap or proportion ſhould prove uneaſy to the performer, another ſound, B, is placed between them, by which, as by a ſtep or degree, we may move upwards or downwards more eaſily, and with leſs exertion of voice.

"Hence

"Hence it appears," continues Deſcartes, "that the degrees are only certain media contrived to be placed between the extremes of concords, for moderating the inequality, and are only of uſe with reſpect to concords, ſo that when the voice has moved one degree, the ear is not ſatisfied till we come to the other, which therefore muſt be concord to the firſt ſound." The ſubſtance of what is here alleged amounts to this; that by a proper diviſion of the concording intervals in ſuch as are leſs remote, the voice will move ſmoothly and gracefully from one ſound to another, and the hearer be prepared for a more exquiſite delight in arriving at the completion of the concord, whoſe extremes are the proper ſounds in which the ear finds its expected reſt and pleaſure.

DEGREES, *for the Uſe of*, in the conſtruction of the ſcale of muſic. See SCALE.

DEGREE, in *Univerſities*, denotes a quality conferred on the ſtudents, or members of them, as a teſtimony of the proficiency in the arts or faculties; and entitling them to certain privileges, precedencies, &c.

The degrees are much the ſame in the ſeveral univerſities: but the laws of them, and the diſcipline or exerciſe previous to their being obtained, differ. The degrees are, *bachelor*, *maſter*, and *doctor*; inſtead of the ſecond, in ſome foreign univerſities, they have *licentiate*.

In each faculty there are but two degrees, *viz. bachelor* and *doctor*, which were anciently called *bachelor* and *maſter*: nor do the arts admit of more than two, which ſtill retain the denomination of the ancient degrees, *viz. bachelor* and *maſter*. At Oxford, degrees of maſter and doctor are only conferred once a year, *viz.* on Monday after the ſeventh of July, when a ſolemn act is held for the purpoſe. See ACT.

The expences of a degree of doctor in any of the faculties in treats and ſet fees, uſually amount to 100*l.*, and thoſe of a maſter of arts to 20 or 30*l.*

The degree of bachelor is only conferred in Lent.

To take the degree of bachelor of arts, four years are required, and three more for maſter of arts. See BACHELOR.

At Cambridge, matters are nearly on the ſame footing, only the diſcipline is ſomewhat more ſevere, and the exerciſes more difficult. The commencement, which anſwers to the act of Oxford, is the Monday before the firſt Tueſday in July. The degrees of bachelor are taken up in Lent, beginning on Aſh-Wedneſday.

The degree of maſter of arts is not given till above three years after that of bachelor; during which time the candidate is obliged, three ſeveral times, to maintain two philoſophical queſtions in the public ſchools, and to anſwer the objections raiſed againſt him by a maſter of arts. He muſt alſo keep two acts in the bachelor's ſchool, and declaim one.

For the DEGREE *of Doctor*, ſee DOCTOR.

DEGREES conferred on muſical ſtudents in our univerſities. The title of *doctor* in muſic, peculiar to the univerſities of our own country, according to Anthony Wood, was firſt conferred in the reign of king Henry II.; but this is fixing it at an earlier period than that in which ſuch a title can be proved to have ſubſiſted at Oxford or Cambridge, or to have been conferred on the profeſſors of other ſciences. Spelman, a more nice and accurate ſifter of facts, believes that the appellation of doctor was not among the degrees granted to graduates in England, till the reign of king John, about 1207.

It is known that this title was created on the continent about the middle of the twelfth century, as more honourable than that of *magiſter*, or maſter, which was become too common. Its original ſignification implied not only learning and ſkill, but abilities to *teach*, according to the opinion of Ariſtotle, who ſays, that the moſt certain proof of knowledge in any ſcience is the being able to inſtruct others. John de Muris begins the ſecond part of his Treatiſe on Muſic with the following paſſage: "Princeps philoſophorum Ariſtoteles ait in principio mathematicæ ſuæ, omnino ſcientis ſignum eſt poſſe docere." Muſices Tract. MS. Bodl. 300.

The firſt degree of this kind which was conferred in a public ſchool or academy, was at Bologna, about the year 1130, where, according to Bayle, it was an honour inſtituted in favour of Irnerius, chancellor to the emperor Lotharius, who was created doctor of civil law. This ceremony ſoon after was adopted in other univerſities, and paſſed from the law to theology.

Peter Lombard is the firſt doctor in ſacred theology upon record in the univerſity of Paris; and John Hambois has been imagined by ſome to be the firſt muſician who was honoured with the title of doctor in England.

The preciſe time when this creation extended to the faculties of medicine and muſic does not appear; nor can the names be found of thoſe profeſſors in either to whom the title was firſt granted.

It has, however, been frequently remarked (Burney's Hiſt. Muſ. vol. ii.) that during the middle ages muſic was always ranked among the ſeven liberal arts, that it was included in the *trivium* and *quadrivium*, and that it was ſtudied by all thoſe who aſpired at reputation for learning throughout Europe. The *trivium* compriſed the three ſciences of grammar, rhetoric, and logic, which teach us how to reaſon with accuracy and preciſion; and the *quadrivium* comprehended arithmetic, muſic, geometry, and aſtronomy, as the four branches of the mathematics which ſilently contemplate whatever is capable of being numbered or meaſured. Now it is remarkable, that, in our univerſities, muſic is the only one of theſe ſeven ſciences that confers degrees on its ſtudents; and, in other countries, though theology, law, and medicine beſtow this honour, which are *not* of the ſeven, yet muſic, which *is*, can aſpire at no ſuch diſtinction.

However, it evidently appears that the muſic which was regarded as a ſcience by our forefathers, was merely ſpeculative, and ſuch as concerned harmonics, the ratio of muſical intervals, and philoſophy of ſound; and in this ſenſe muſical degrees are perhaps but ſeldom conferred in our univerſities according to the original ſpirit of the inſtitution. But the preſent ſtatutes, not wholly neglecting the gratification of the ear, are more favourable to practical muſic, and allow candidates for degrees to perform exerciſes, in which ſpecimens may be furniſhed of their ſkill in melody, harmony, and compoſition, where thoſe ſounds are arranged and combined which ſcience meaſures and fixes by calculation.

By the ſtatutes of the univerſity of Oxford, it is required of every proceeder to the degree of bachelor in muſic, that he employ ſeven years in the ſtudy or practice of that faculty, and at the end of that term, produce a teſtimonial of his having ſo done, under the hands of credible witneſſes; and that previous to the ſupplication of his grace towards this degree, he compoſe a ſong of five parts, and perform the ſame publicly in the muſic-ſchool, with vocal and inſtrumental muſic, firſt cauſing to be affixed on each of the doors of the great gates of the ſchools a programma, giving three days notice of the day and hour of each performance. Of a bachelor proceeding to the degree of doctor, it is required that he ſhall ſtudy five years after the taking his bachelor's degree, and produce the like proof of his having ſo done as

is requiſite in the caſe of a bachelor; and farther, ſhall compoſe a ſong in ſix or eight parts, and publicly perform the ſame "tum vocibus quam inſtrumentis etiam muſicis," on ſome day to be appointed for that purpoſe, previouſly notifying the day and hour of performance in the manner before preſcribed. Such exerciſe to be performed in the preſence of Dr. Heyther's profeſſor of muſic. This being done, the candidate ſhall ſupplicate his grace in the convocation-houſe, which being granted by both the Savilian profeſſors, or by ſome maſter of arts deputed by them for that purpoſe, he ſhall be preſented to his degree.

It is obſerved by the authors of the "Hiſtoire litteraire de la France," tom. vii. p. 142, and tom. ix. p. 200, that in the ſemi-barbarous ages, muſic was in ſuch high eſtimation, that no one could omit the ſtudy of it who cultivated letters. The learned Gerbert, who arrived at the pontificate by the title of Sylveſter II., and many other illuſtrious perſonages, regarded it as the ſecond branch of mathematics. But if muſic does no honour to the ſciences at preſent, it is little indebted to them for the diſtinction of being admitted into their company during ſo many ages, as ignorant artiſts of talents and ſenſibility have perhaps contributed more to her perfection, than all the ſublime reveries and profound calculations of men of ſcience.

The firſt qualification for the degree either of bachelor or doctor in muſic, was formerly the reading and expounding of certain books in Boethius, as the only writings whence knowledge in the principles of the ſcience could be acquired. (See the ſtatutes of the univerſity.) But the candidate for academical degrees is no longer put to this teſt; he is now to compoſe an exerciſe for voices and inſtruments in ſix or eight parts, which he is to ſubmit to the inſpection of the muſic profeſſor, and to have publicly performed in the muſic ſchool of the univerſity.

Wood, in his Faſti, has been able to produce no names of muſicians that have been enrolled among the graduates of the univerſity of Oxford before the ſixteenth century, though we are told of ſeveral at Cambridge of an earlier period. Whether Hambois was a member of this univerſity, or of Oxford, does not appear, nor indeed is it preciſely known at what time he received his diploma. In Hollinſhed's chronicle, vol. ii. p. 1355, there is an enumeration of the moſt eminent men of learning in the reign of Edward IV. among whom the author includes John Hamboys, "an excellent muſician," adding, that "for his notable cunning therein, he was made a doctor of muſic." But academical honours in the faculty of muſic may be traced up to the year 1463, when Henry Habengton was admitted to the degree of bachelor of muſic at Cambridge, and Thomas Saintwix, doctor in muſic, was made maſter of king's college in the ſame univerſity.

DEGUELIA, in *Botany*, Aublet Guian. 750. *t.* 300. Juſſ. 363, a ſhrub, three or four feet high, with long, twining branches, pinnate leaves, and ſmall white ſpicate-papilionaceous flowers, is known only by the deſcription and plate of Aublet, who found it near the banks of rivers in Guiana. Juſſieu ſuſpects it to belong to the genus *Geoffræa*.

DEHAM, a town of Arabia, in the country of Yemen; 28 miles W.N.W. of Sana.

DEH-Bouzour, in *Geography*, a town of Perſia, in the province of Irak; 80 miles N.N.W. of Iſpahan.

DEHCHAR, a town of Perſia, in the province of Kerman; 70 miles S.W. of Sirgian.

DEH-Couchek, a town of Perſia, in the province of Irak; 48 miles N.W. of Iſpahan.

DEHDANAH, a town of Perſia, in the province of Khoraſan; 60 miles N.E. of Herat.

DEHEWBARTH, one of the ſix principalities into which Wales was divided about the cloſe of the ſixth century; the other five were Gwynedd, Powys, Reynnuc, Eſylluc, and Morgannuc; but the moſt permanent diviſion of the Britiſh territories about this time was into three principalities or kingdoms; *viz.* Dehewbarth, Powyſland, and Gwynedd. Dehewbarth, now South-Wales, was the country of the brave Silures; and was anciently divided into the ſix diſtricts of Cairdigan, now Cardiganſhire, Dyvat, now Pembrokeſhire, Cairmarden, now Caermarthenſhire, Morgannuc, now Glamorganſhire, Guent, now Monmouthſhire, and Brecknock, or Brecknockſhire. The chief reſidence, or capital of the ancient princes of South-Wales, was Cairmarden, and ſometimes Dinevor caſtle.

DEHI-COUH, or Dehaka, a town of Perſia, in the province of Lariſtan; 9 miles W. of Lar.

DEHI-DOMDE, a town of Perſia, in the province of Farſiſtan; 100 miles S.E. of Schiras.

DEHI-GHERDOU, a town of Perſia, in the province of Farſiſtan; 100 miles N. of Schiras.

DEHI-KOURD, a town of Perſia, in the province of Lariſtan; 21 miles N.W. of Lar.

DEHISCENTIA, a ſplitting or ſeparation of parts, in *Vegetable Phyſiology*, is particularly applied to the opening of capſules, or dry ſeed-veſſels, when they arrive at maturity. The word is alſo uſed for the ſeaſon when this principally happens.

Moſt capſules are ſo conſtructed, that while juicy and verdant, they remain cloſed, but when dry, they either ſplit aſunder by the elaſticity of their valves, ſometimes, as in *Euphorbia* and its allies, with great force; or their thin ſides ſhrivel and ſhrink, thus forming apertures, as in the Poppy, the Lily, and with great regularity and beauty in ſome ſpecies of *Ariſtolochia*. By this contrivance the ſeeds are diſperſed in dry weather, which is moſt favourable to their ſucceſs. Some annual ſpecies of *Meſembryanthemum* have however been diſcovered in the ſandy deſerts of Africa, whoſe capſules expand, and ſcatter their ſeeds, in wet weather only, rain being of ſuch rare occurrence there, that they might otherwiſe lie too long expoſed, before they could meet with ſufficient moiſture to vegetate. See Sm. Introduction to Botany, 277. *t.* 14. *f.* 178.

DEHNE, in *Geography*, a town of Perſia, in the province of Khoraſan; 108 miles E. of Meſchid.

DEHORS, Fr. *without*, in *Law*, a word uſed in ancient pleading, when a thing is *without* the land, &c. or *out* of the point in queſtion. See Hors *de ſon fee*.

DEHTIEZ, in *Geography*, a town of Hungary; 15 miles N.W. of Leopoldſtadt.

DEICIDE, Deicida, from *Deus*, *God*, and *cædo*, *I kill*, a term only uſed by ſome writers in ſpeaking of the condemnation and execution of the Saviour of the world, by Pontius Pilate and the Jews.

Some have objected to the propriety of the term, ſince Chriſt ſuffered and died, not as God, but as man,

DEIDIER, Anthony, in *Biography*, a voluminous writer on almoſt every branch of medicine, was the ſon of a ſurgeon of Montpellier. In 1691 he was made doctor in medicine, and in 1697 profeſſor of chemiſtry. He was alſo honoured with the cordon of the order of St. Michael, and was admitted one of the foreign members of the royal ſociety of London. In 1732, being appointed phyſician to the galleys, he quitted Montpellier, and went to Marſeilles, where he died on the 3d of April 1746. Of his works the following have been

been moſt noticed: "Experiences ſur la Bile, et les cadavres des peſtiferes, faites par M.D.; accompagnees des Lettres, &c." Zurich, 1772. He was at Marſeilles while the plague raged there. He attributed the diſeaſe to a prevailing acid. He injected bile taken from perſons who had died of the plague into the veins of ſome dogs, which were almoſt immediately killed by the venom: A ſenſeleſs experiment, from which no uſeful reſult could be expected to follow. He tried inunctions with mercury in the diſeaſe; from which, he ſays, no benefit nor miſchief was found to accrue. "Chymie raiſonnee, ou l'outache de decouvrir la nature et la maniere d'agir des remedes chymiques les plus en uſage en medicine et en chirurgie." Lyon, 1715, 12mo. Theſe experiments were alſo fruitleſs; they ſhew, however, an active and inquiſitive turn of mind, which, properly directed, might have been productive of ſome profits. In his treatiſe on the venereal diſeaſe, he ſuppoſes the diſeaſe to be occaſioned by a particular ſpecies of inſect, which mercury had the power of deſtroying. He publiſhed three volumes of conſultations and obſervations, which may be read with advantage, the diſeaſes being generally correctly deſcribed, and the method of treating them ſuch as is now commonly practiſed. For the titles and accounts of the remainder of his works, ſee Haller's Bib. Med. Eloy. Dict. Hiſt.

DEJECTION, in *Aſtrology*, is applied to the planets, when in their detriment, as aſtrologers ſpeak, *i. e.* when they have loſt their force, or influence, as it is pretended, by reaſon of their being in oppoſition to ſome others, which check and counteract them.

Or, it is uſed when a planet is in a ſign oppoſite to that wherein it has its greateſt effect, of influence, which is called its exaltation. Thus the ſign Aries being the exaltation of the Sun, the ſign Libra is its dejection. See EXALTATION.

DEJECTION, in *Medicine*, from *dejicio, I throw off*, properly ſignifies the act of ejecting or evacuating the excrements. But it is alſo more commonly applied to the excrements themſelves, thus evacuated; in which ſenſe it is of the ſame import with *ſtool*.

An examination of the condition of the alvine excretions is highly important in the treatment of all acute, and many chronic, diſeaſes; inaſmuch as the ſenſible qualities of the excrement indicate, in a conſiderable degree, the various diſordered ſtates of the organs of digeſtion, and the alimentary canal, and more particularly of the liver. For, although, in many caſes, both of acute and chronic diſorder, theſe morbid conditions of the digeſtive organs are the effect of the general, or of ſome local derangement of health; yet they become, perhaps in all caſes, by a re-action on the conſtitution, the cauſes of a continuance of the original maladies, or of new complaints. It has lately been demonſtrated, that many diſeaſes of the ſyſtem at large either depend altogether upon the morbid ſtate of the chylopoietic viſcera, indicated by unnatural fœces, or are ſo connected with it, as to ceaſe when that morbid ſtate is removed by medicine. See CATHARTIC, and CHOREA.

The ancients did not fail to pay attention to the ſtools, as well as the other evacuations of the ſick; and they deduced their practical inferences, according to their humoral pathology, from the ſuppoſed crude or concocted ſtate of the fœces. But this hypotheſis ſeems to be leſs correctly applicable to the alvine, than to ſome other diſcharges; and the concoction of the excretions by ſtool appears to have only ſignified in general their approach to the natural or healthy appearance, and the term crude to have included all the various morbid appearances, which they exhibited. See CRUDITY and CONCOCTION.

In diſeaſes of the digeſtive organs and inteſtines themſelves, the nature of the dejections affords ſome of the diagnoſtic ſigns of the nature of the diſeaſes. In dyſentery, for example, in which the mucous coat of the inteſtines is inflamed, the paſſage conſtricted, and the fœcal matter detained, the ſtools conſiſt principally of the ſlime or mucus of the bowel, or, in more violent caſes, of blood only; and the fœcal matter, if any be diſcharged, is in the form of hard balls, or ſcybala: in the more advanced ſtages, when ulceration has taken place, pieces of coagulated lymph, like membranes, are diſcharged, with ſanious matter. In ſimple diarrhœa, the fœcal matter, though diluted with the ſerous effuſion from the exhalent veſſels of the canal, or mixed with portions of undigeſted aliment, paſſes off nevertheleſs, retaining moſt of its other natural qualities. When the ſecretion of bile, or its paſſage into the inteſtines, is interrupted in adults, as in jaundice, the ſtools are clayey, and pale, like whitiſh-brown paper. In children, when that ſecretion is ſtopped by the irritation of teething, their diet being chiefly of bread and milk, the fœces are white; and when digeſtion is diſordered, the biliary ſecretion going on, acid is generated in the ſtomach, which, mixing with the bile, gives the alvine diſcharges a green colour. Inſtances occaſionally occur, in which a fluid like coffee-grounds in colour and conſiſtence is vomited, and ſimilar matter, of a darker colour and of an offenſive ſmell, is diſcharged in great quantities *per anum*; ſometimes green bile is obſerved mixed with theſe diſcharges, ſometimes none. They conſiſt undoubtedly of blood ſlowly evacuated, ſometimes ariſing from the inner ſurface of the inteſtines, ſometimes from the liver, and generally occur in ſpirit-drinkers. This diſeaſe has been termed MELÆNA (μελαινα, black diſeaſe). On the examination of the bodies of perſons who have died of ſuch attack, the lining of the inteſtinal canal has been found highly inflamed, and apparently tending to mortification, through the whole extent, ſometimes with and at other times without any diſeaſe of the liver.

In many nervous and febrile diſorders of the conſtitution, as in chorea, St. Vitus's dance, in hyſteria, in typhus, and ſcarlatina, as ſhewn by Dr. Hamilton; and in ſome more local affections, as pointed out by Mr. Abernethy; the ſtools, by their unnatural colour, and fœtid odour, indicate diſorder in the chylopoietic organs; and eſpecially, as Mr. Abernethy maintains, in the liver and its ſecretion, the bile. Medical men, he obſerves, entertain various opinions reſpecting the colour of the fœces; but to him this property ſeems generally to depend on the kind and quantity of the bile. All the ſecretions, which are poured into the alimentary canal, except the bile, are colourleſs, or white; if, therefore, this fluid were wanting, the reſidue of the aliment would be of the colour, which might be expected to reſult from ſome of its undigeſted parts combined; and this is the caſe in jaundice, and ſometimes in children, during dentition, as before mentioned. The fœces, voided during a ſtate of diſorder of the digeſtive organs, are ſometimes partially coloured; which circumſtance cannot be well accounted for upon any other ſuppoſition, than that of an irregular ſecretion of the bile. Beſides, fluids ſecreted from the inteſtines do not uſually enter into combination with the fœcal matter, but appear diſtinctly when excreted. Thus we find mucus and jelly diſcharged from the bowels, unmixed with the fœces. And, laſtly, medicines which affect the liver, produce a very ſudden change in the colour of the fœces. Small doſes of mercury, without any alteration of diet, ſometimes change the ſtools immediately from a blackiſh to a light

a light yellow colour, which indicates a healthy but deficient ſecretion of bile. Healthy bile, in the human ſubject, is generally of a deep yellow brown colour; the brown ſeems to be the reſult of the yellow colour concentrated. Mr. Abernethy compares it to the colour of wetted rhubarb: for if a ſmall portion of either of theſe ſubſtances be put into a large quantity of water, it will dye it of a bright yellow colour; which is actually the colour of theſe ſubſtances, yet it is ſo concentrated in the maſs as to appear of a deep brown. The quantity of this fluid ſhould be ſuch as completely to dye the excrement of its peculiar colour. By attending, therefore, to the colour of the fœces, the kind and quantity of bile, which the liver excretes, may in general be aſcertained.

The colour of the alvine excretions in theſe diſordered ſtates of the viſcera, is various. Sometimes they appear to conſiſt of the reſidue of the food, untinged in the leaſt degree with bile. Sometimes they are of a light yellow colour, which denotes a very deficient quantity of healthy biliary ſecretion. They may alſo be of a deep olive, of a clay brown, and of a blackiſh brown; all of which ſhew a vitiated ſtate of the biliary ſecretion. Any kind of brown, which dilution will not convert into yellow, muſt be conſidered, according to Mr. Abernethy's principle, as unhealthy; ſince the colour of the healthy bile is a bright yellow, which by concentration appears brown.

The effects, which medicine or diet may have upon the colour of the fœces, ought, however, to be conſidered. When the food is coloured, and this colour is not altered by digeſtion, it will, of courſe, appear in the fœces; hence if it ſhould be thought deſirable to know accurately the ſtate of the biliary ſecretion, it would be right to reſtrict patients to a diet that is not likely to colour the fœces. In acute diſeaſes, however, as little or no food is taken, this conſideration is ſuperfluous. The green colouring matter of vegetables tinges the fœcal reſidue of the food. Steel is alſo known to influence the colour of the fœces, as well as the red varieties of cinchona, and ſeveral other drugs. It ſhould alſo be remarked, that the expoſure of fœces to air, after their expulſion, will in ſome inſtances cauſe a conſiderable alteration of their colour. In our endeavours, therefore, to aſcertain whether the liver is performing its office rightly, by obſerving the colour of the fœces, attention ſhould be paid to ſuch circumſtances, leſt we ſhould deceive ourſelves.

The reſidue of the alimentary matter, mixed with the bile, paſſes from the ſmall into the large inteſtines, and there undergoes a ſudden change; it acquires a peculiar fœtor, and becomes what we denominate fœces. This change is ſo ſudden, that it cannot be aſcribed to ſpontaneous chemical alterations, (which would be gradual,) but to ſome new animal agency. If the contents of the ſmall inteſtines at their termination, and of the large at their commencement, be examined, they will be found totally different even within a line of each other; the former being without fœtor, and the latter being in all reſpects what is denominated fœces. The fœces quickly ſuffer chemical decompoſition out of the body, although they often remain in the bowels, without undergoing the ſame kind of change. Their chemical decompoſition is attended with the ſudden formation of ammonia; yet if they be examined when recent, they are found to contain acids which ammonia would neutralize. The inference, therefore, naturally ariſes, that this agency of the large inteſtines may be deſigned, among other purpoſes, ſo to modify the reſidue of the alimentary matter, as to prevent it from undergoing thoſe various chemical changes, which might be ſtimulating to the containing organs, as well as injurious to the general health. In a perfectly healthy ſtate of the digeſtive organs, probably no chemical decompoſition, even of the fœces, takes place; yet ſuch changes happen in ſome degree, without apparently producing any injurious conſequences. To chemical changes we may probably attribute the extrication of inflammable air, and the various and unnatural odour of the fœcal matter, which is obſervable in diſordered ſtates of the digeſtive viſcera. Analogy would lead us to refer the changes, produced in the large inteſtines, to the effects of a ſecretion from their lining membrane, which ſecretion of courſe will be deranged by a diſordered and irritated ſtate of the organs, and a correſponding derangement of the fœcal proceſs muſt be expected to enſue. See Abernethy, Surgical Obſervations, vol. ii.

Dr. Hamilton, however, ſeems to be of opinion, that the fœces undergo a change, when long detained in the inteſtines, which this change of colour and ſmell indicates, and he attributes much to the ſtate of conſtipation or accumulation of fœces in the bowels, which this morbid condition of the dejections accompanies. Hence he conſiders dark and fœtid excretions from the bowels as indicating the neceſſity of purgative medicines; which experience has ſhewn to be ſalutary under ſuch circumſtances, whether in nervous, febrile, or other complaints. See Obſervations on Purgative Medicines.

The neceſſity of removing theſe morbid fœces by cathartics, which alſo ſtimulate the bowels, and the adjoining viſcera, the liver, and pancreas, is the inference likewiſe drawn by Mr. Abernethy, from his view of the ſubject.

The digeſtive organs are peculiarly liable to derangement in children, ſo that every diſeaſe in them, whether in the teeth, the lungs, or elſewhere, is accompanied with a diſcharge of unhealthy ſtools, and laxatives are therefore powerful auxiliaries in the cure of the majority of their complaints.

DEJECTORIA, denote purging medicines.

DEI FACIES *Promontorium*, in *Ancient Geography*, a promontory more commonly called from the Greek *Theoproſopon*, ſituated on the coaſt of Phœnicia, between Tripolis to the north, and Botrus or Botrys to the ſouth.

DEIFAN, in *Geography*, a town of Arabia, in the country of Yemen; 32 miles north of Sana.

DEIFICATION, in the *Pagan Theology*, the act, or ceremony, of deifying their emperors, *i. e.* of placing them among the gods, and decreeing divine honours to be rendered them. The deification is the ſame with *apotheoſis*; which ſee.

The deification of the emperors is the only inſtance in which they departed from their accuſtomed prudence and modeſty. The Aſiatic Greeks were the firſt inventors, and the ſucceſſors of Alexander the firſt objects of this ſervile and impious mode of adulation. It was eaſily transferred from the kings to the governors of Aſia; and the Roman magiſtrates very frequently were adored as provincial deities, with the pomp of altars and temples, of feſtivals and ſacrifices. (Mengault in vol. i. Acad. Inſcript.) It was natural that the emperors ſhould not refuſe what the proconſuls had accepted; and the divine honours, which both the one and the other received from the provinces, atteſted rather the deſpotiſm than the ſervitude of Rome. But the conquerors ſoon imitated the vanquiſhed nations in the arts of flattery; and the imperious ſpirit of the firſt Cæſar too eaſily conſented to aſſume, during his lifetime, a place among the tutelary deities of Rome. The milder temper of his ſucceſſor declined ſo dangerous an ambition, which was never afterwards revived, except by the madneſs of Ca-

ligula and Domitian. Auguſtus, indeed, permitted ſome of the provincial cities to erect temples to his honour, on condition that they ſhould aſſociate the worſhip of Rome with that of the ſovereign; he tolerated private ſuperſtition, of which he might be the object; but he contented himſelf with being revered by the ſenate and people in his human character, and wiſely left to his ſucceſſor the care of his public deification. A regular cuſtom was introduced, that on the deceaſe of every emperor, who had neither lived nor died like a tyrant, the ſenate by a ſolemn decree ſhould place him in the number of the gods; and the ceremonies of his apotheoſis were blended with thoſe of his funeral. This loyal, and, as it ſhould ſeem, injudicious profanation, ſo abhorrent to our ſtricter principles, was received with a very faint murmur (Cicero in Philippic. i. 6. Julian in Cæſaribus.) by the eaſy nature of polytheiſm; but it was received as an inſtitution, not of religion, but of policy. We ſhould diſgrace the virtues of the Antonines, by comparing them with the vices of Hercules or Jupiter. Hence the characters of Cæſar or Auguſtus were far ſuperior to thoſe of the popular deities. But it was the misfortune of the former to live in an enlightened age, and their actions were too faithfully recorded to admit of ſuch a mixture of fable and myſtery, as the devotion of the vulgar requires. As ſoon as their divinity was eſtabliſhed by law, it ſunk into oblivion, without contributing either to their own fame, or to the dignity of ſucceeding princes. Gibbon's Hiſt. vol. i.

DEIGGITSCH, in *Geography*, a river of Germany, which runs into the Kainach, about a mile ſouth-eaſt from Voitſberg.

DEI JUDICIUM, in *Antiquity*, a name given to the old Saxon trial by ordeal; becauſe they thought it an appeal to God, for the juſtice of a cauſe, and verily believed that the deciſion was according to the will and pleaſure of divine providence. See ORDEAL.

DEINCLINERS, or DEINCLINING *dials*, are ſuch as both decline, and incline or recline, at the ſame time.

Suppoſe, for inſtance, a plane to cut the prime vertical circle at an angle of 30 degrees, and the horizontal plane under an angle of 24 degrees, the elevation of the pole being 52 degrees; a dial, drawn on this plane, is called a *deincliner*. See DIAL.

DEINEK, in *Geography*, a town of European Turkey, in the province of Moldavia; 36 miles weſt of Birlet.

DE INJURIA *ſua propria, abſque tali cauſa*, in *Law*, are words uſed in replications, in actions of treſpaſs. (1 Lil. Abr. 427.) When one juſtifies by command or authority derived from another, or if a defendant juſtifies by authority at common law, as a conſtable by arreſt for breach of the peace; or if he juſtifies by act of parliament, &c.; the plaintiff may reply that he did it of *his own wrong, without any ſuch cauſe as the defendant has alleged*. Cro. Eliz. 539. 2 Salk. 628. See TRESPASS.

DEINSBURG, in *Geography*, a town of Germany in the duchy of Carinthia; 5 miles north of Ebernſtein.

DEINSE, DEINZE, or DEYNSE, a ſmall town of France, in the department of the Eſcaut, chief place of a canton in the diſtrict of Gand, with a population of 2958 individuals, nine miles ſouth-weſt of Gand, and 15 north-eaſt of Courtray. The canton has an extent of 85 kiliometres, 10 communes, and 17,158 inhabitants.

DEJOCES, in *Biography*, the firſt king of the Medes, raiſed to that honour from the rank of citizen, on account of his zeal in the adminiſtration of juſtice and equity among his countrymen. His influence as a private man was ſo great, that when he ceaſed to act, anarchy and confuſion ſeemed always and immediately to prevail: he was, in conſequence of this, choſen ſovereign about the year B. C. 709. He ſoon obtained all the honours attaching to that rank in life, and did not fail to magnify the importance of his ſituation; and to excite in the minds of his ſubjects an awe of his perſon, he would not ſuffer himſelf to be ſeen by any but thoſe of his immediate houſehold. He tranſacted all his buſineſs through the medium of ſervants and miniſters. By theſe means, and by employing a multitude of ſpies in all parts of his dominions, he eſtabliſhed a perfect deſpotiſm, which he adminiſtered with judgment, and with ſome degree of ſeverity. He reigned 53 years; and at his death was ſucceeded by his ſon Phraortes. Univer. Hiſt.

DEJOTARUS, firſt diſtinguiſhed as tetrarch of Galatia, and on account of the eminent ſervices which he performed in that ſtation, and of the figure which he made in the Mithridatic war, was afterwards appointed to the throne of the Leſſer Armenia by Pompey, which appointment was confirmed by the ſenate. He was highly reſpected by moſt of the principal people in Rome, and was of much ſervice in repreſſing many tumults which were excited in the empire. In the civil war between Pompey and Cæſar, he ſided with the former, and was on that account deprived of part of his territory, and became tributary to the victorious Cæſar. After his death, Dejotarus, by bribery, recovered his forfeited territories. He intended next to have joined Brutus, but the commander to whoſe care he truſted his troops went over to Antony, which was ſo far fortunate for him, that on the defeat of Brutus he was permitted to retain his kingdom. He arrived to an advanced age, and, towards the cloſe of life, was exceſſively devoted to the ſuperſtitions of the age and country in which he lived, and was governed almoſt entirely by omens and auguries. See BAYLE, who has given a very elaborate and learned article of this prince.

DEIPARA, Θεοτοκος. See MOTHER *of God*.

DEIRA, in *Ancient Geography*, one of the two kingdoms, into which the 7th kingdom of the heptarchy, or Northumberland, was divided; comprehending the country between the Humber and the Tyne, whoſe capital was York. The other of theſe two kingdoms was Bernicia, or the country between the Tyne and the Forth, whoſe capital was Bamburgh. Theſe two kingdoms were united by Oſwald about the middle of the 7th century, into the kingdom of Northumberland.

DEIR-ABULISE, in *Geography*, a town of Egypt; 45 miles ſouth-weſt of Cairo.

DEIRGEART LOUGH, often called *Lough Derg*, a very large ſheet of water in Ireland, into which the river Shannon expands, between the counties of Galway and Clare on one ſide, and Tipperary on the other. This lake is about 16 miles long, and from two to ſix in breadth, and contains ſome, though not many, iſlands.

DEIROUT, or DEIRÛT, a large and handſome town of Egypt, ſituated on the weſtern bank of the Nile, almoſt oppoſite to Foueh, and about 16 miles ſouth-eaſt of Roſetta.

DEIS, or DAIS, the chief table in a monaſtery. "Solus in refectorio prandebit ſupremus habens vaſtellum, priore prandente ad magnam menſam quam *deis* vulgariter appellamus."

It is thus called from a cloth called dais, with which the tables of kings were covered.

DEISM, the doctrine or belief of the Deiſts.

Deiſm, *Theiſm*, from Θεος, *God*, may properly be uſed to denote natural religion, as comprehending thoſe truths which have a real foundation in reaſon and nature; and in this ſenſe it is ſo far from being oppoſite to Chriſtianity, that it is one great deſign of the Goſpel to illuſtrate and enforce

enforce it. Thus ſome of the deiſtical writers have affected to uſe it; but deiſm more preciſely ſignifies that ſyſtem of religion, relating both to doctrine and practice, which every man is to diſcover for himſelf by the mere force of natural reaſon, independent of all revelation, and excluſive of it; and this religion Dr. Tindal, and others, pretend is ſo perfect, as to be incapable of receiving any addition or improvement, even from divine revelation.

It has not been, however, uncommon to boaſt of the perfection of this religion in conſequence of the aſſiſtance which it has received from revelation, though its advocates are neither ſufficiently humble nor candid to acknowledge it. Natural religion, with the clear views and extraordinary helps which it derives from the Scriptures of divine truth, is very different with regard to extent and evidence, from what it would have been without ſupernatural direction and aſſiſtance. It is not eaſy to determine what unaided reaſon might have done, and how far it might have diſcovered the principles and duties of religion; becauſe, in every period of time, its powers have been more or leſs aſſiſted by divine revelation, the benefits of which have been tranſmitted from one age to another. Under the diſpenſation of Chriſtianity, more eſpecially, men have been taught to reaſon juſtly concerning religious truth and duty by the aid of revelation, though they have not duly acknowledged their obligations. It therefore becomes thoſe who urge the perfection of natural religion as an argument againſt the neceſſity of divine revelation, to conſider to what this perfection is owing; and whether they are not indebted for it to thoſe extraordinary communications, of which they have availed themſelves, and which, being no farther neceſſary, they depretiate and diſcard. Some perſons, however, whilſt they have boaſted of the perfection of natural religion, have diſparaged Chriſtianity on account of the difficulties that embarraſs the inveſtigation of ſome of its doctrines and diſcoveries. It behoves ſuch perſons to conſider how far this kind of reaſoning may be urged againſt other ſyſtems both of religion and philoſophy, which they themſelves profeſs to admit. Are there not in *deiſm* itſelf, the moſt ſimple, as it is deemed, of all religious opinions, ſeveral difficulties, for which human reaſon can but ill account, which may therefore be not improperly ſtyled "articles of faith?" Such is the origin of evil under the government of an all-good and all-powerful God; ſuch is the reconciling of the preſcience of God, with the free-will of man, which, after much thought on the ſubject, Mr. Locke, (Letter to Mr. Molyneux, p. 509, vol. iii.) fairly confeſſes he could not do, though he acknowledges both; ſuch is alſo the creation of the world at any ſuppoſed time, or the eternal production of it from God, &c. &c. But becauſe of theſe difficulties, or any others that may occur in the ſyſtem of deiſm, no wiſe man will deny the *being* of God; or his *infinite wiſdom, goodneſs*, and *power*, which are proved by ſuch evidence as carries the cleareſt and ſtrongeſt conviction, and cannot be refuted without involving the mind in *far greater difficulties*, even in downright *abſurdities* and *impoſſibilities*. The only part, therefore, that can be taken is, to account in the beſt manner that our weak reaſon is able to do, for ſuch ſeeming objections; and when *that* fails, to acknowledge its weakneſs, and acquieſce under the certainty that our very imperfect knowledge or judgment cannot be the meaſure of the divine wiſdom, or the univerſal ſtandard of truth. So it is likewiſe with reſpect to the *Chriſtian religion*. Some *difficulties* occur in that revelation, which human reaſon can hardly clear; but as the truth of it ſtands upon evidence ſo ſtrong and convincing, that it cannot be denied without much *greater difficulties* than thoſe that attend the belief of it, we ought not to reject it upon ſuch objections, however mortifying they may be to our pride. *That* indeed would have all things made plain to us; but God has thought proper to proportion our knowledge to our *wants*, not to our *pride*. All that concerns our *duty* is clear; and as to other points either of natural or revealed religion, if he has left ſome obſcurities in them, is that any reaſonable cauſe of complaint? Not to rejoice in the benefit of what he has graciouſly allowed us to know, from a preſumptuous diſguſt at our incapacity of knowing more, is as abſurd as it would be to refuſe to *walk*, becauſe we cannot *fly*. From the arrogant ignorance of metaphyſical reaſonings, aiming at matters above our knowledge, aroſe all the ſpeculative impiety, and many of the worſt ſuperſtitions, of the old Heathen world, before the Goſpel was preached to bring men back again to the primitive faith; and from the ſame ſource have ſince flowed ſome of the greateſt corruptions of the evangelical truth, and the moſt inveterate prejudices againſt it; an effect juſt as natural as for our eyes to grow weak and even blind, by being ſtrained to look at objects too diſtant, or not made for them to ſee. If the *external* evidence of our religion be convincingly ſtrong, and there is no *internal* proof of its falſehood, but much to ſupport and confirm its truth; then ſurely no difficulties ought to prevent our giving a full aſſent and belief to it. It is our duty indeed to endeavour to find the beſt ſolutions we can to them; but where no ſatisfactory ones are to be found, it is no leſs our duty to acquieſce with humility, and believe that to be right which we know is above us, and belonging to a wiſdom ſuperior to ours. In the preſent compariſon of deiſm with Chriſtianity, and in contraſting the one againſt the other, with a view to the perfection of either, we have been led to mention the difficulties that attend both the one and the other; but the difficulties to which we refer, as peculiar to Chriſtianity, are ſuch as attend the belief of the Goſpel in ſome of its pure and eſſential doctrines, plainly and evidently delivered; which, being made known to us by a *revelation* ſupported by *proofs* that our reaſon *ought to admit*, and not being ſuch things as it could *certainly know to be falſe*, muſt be received by it as *objects of faith*, though they are ſuch as it could not have diſcovered by any natural means, and ſuch as are difficult to be conceived, or ſatisfactorily explained, by its limited powers. If the *glorious light of the Goſpel* be ſometimes overcaſt with clouds of doubt, ſo is the light of our *reaſon* too. But ſhall we deprive ourſelves of the advantage of *either*, becauſe thoſe clouds cannot perhaps be entirely removed, while we remain in this mortal life? Shall we obſtinately and frowardly ſhut our eyes againſt "that day-ſpring from on high that hath viſited us," becauſe we are not as yet able to bear the full blaze of his beams? Shall man preſume that his weak and narrow underſtanding is ſufficient to guide him *into all truth*, without any need of *revelation* or *faith?* Shall he complain that "the ways of God are not like his ways, and paſt his finding out?" True philoſophy, as well as true Chriſtianity, would teach us a wiſer and more modeſt part. It would teach us to be content within thoſe bounds which God has aſſigned to us, "caſting down imaginations, and every high thing that exalteth itſelf againſt the knowledge of God, and bringing into captivity every thought to the obedience of Chriſt." Lyttelton on the Converſion of St. Paul.

DEISTS, a claſs of people known alſo under the denomination of *Free-thinkers*, whoſe diſtinguiſhing character it is, not to profeſs any particular form, or ſyſtem, of religion; but only to acknowledge the exiſtence of a God, and to follow the light and law of nature, rejecting revelation, and oppoſing Chriſtianity.

This name ſeems to have been firſt aſſumed, as the denomination of a party, about the middle of the ſixteenth century,

tury, by ſome gentlemen in France and Italy, who were deſirous of thus diſguiſing their oppoſition to Chriſtianity by a more honourable appellation than that of atheiſts. Viret, an eminent reformer, mentions certain perſons in his epiſtle dedicatory, prefixed to the ſecond tome of his "Inſtruction Chretienne," publiſhed in 1563, who called themſelves by a new name, that of Deiſts. Theſe, he tells us, profeſſed to believe in God, but ſhewed no regard to Jeſus Chriſt, and conſidered the doctrines of the apoſtles and evangeliſts as fables, and dreams. He adds, that they laughed at all religion, though they outwardly conformed to the religion of thoſe with whom they lived, or whom they wiſhed to pleaſe, or feared to offend. Some, he obſerves, profeſſed to believe the immortality of the ſoul; others denied both this doctrine and that of providence. Many of them were conſidered as perſons of acute and ſubtil genius, and took pains in diſſeminating their notions. See Bayle's Dict. art. VIRET. vol. v. or Leland's View of the Deiſtical Writers, vol. i. p. 2.

The Deiſts hold, that, conſidering the multiplicity of religions, the numerous pretences to revelation, and the precarious arguments generally advanced in proof thereof, the beſt and ſureſt way is, to return to the ſimplicity of nature, and the belief of one God; which is the only truth agreed to by all nations.

They complain that the freedom of thinking and reaſoning is oppreſſed under the yoke of religion; and that the minds of men are ridden, and tyrannized, by the neceſſity impoſed on them of believing inconceivable myſteries; and contend, that nothing ſhould be required to be aſſented to, or believed, but what their reaſon clearly conceives. See DEISM.

The diſtinguiſhing character of modern Deiſts is, that they reject all revealed religion, and diſcard all pretences to it, as the effects of impoſture and enthuſiaſm. They profeſs a regard for natural religion, though they are far from being agreed in their notions concerning it. They are claſſed by ſome of their own writers into mortal and immortal Deiſts: the latter acknowledging a future ſtate, and the former denying it, or repreſenting it as very uncertain. Oracles of Reaſon, p. 99.

Dr. Clarke diſtinguiſhes four ſorts of Deiſts. 1. Thoſe who pretend to believe the exiſtence of an eternal, infinite, independent, intelligent Being, who made the world, without concerning himſelf in the government of it. 2. Thoſe who believe the being and natural providence of God, but deny the difference of actions, as morally good or evil, reſolving it into the arbitrary conſtitution of human laws; and therefore they ſuppoſe that God takes no notice of them. With reſpect to both theſe claſſes, he obſerves that their opinion can conſiſtently terminate in nothing but downright atheiſm. 3. Thoſe who having right apprehenſions concerning the nature, attributes, and all-governing providence of God, ſeem alſo to have ſome notion of his moral perfections, though they conſider them as tranſcendent, and ſuch in nature and degree, that we can form no true judgment, nor argue with any certainty concerning them: but they deny the immortality of human ſouls, alleging that men periſh at death, and that the preſent life is the whole of human exiſtence. 4. Thoſe who believe the exiſtence, perfections, and providence of God, the obligations of natural religion, and a ſtate of future retribution, on the evidence of the light of nature, without a divine revelation: ſuch as theſe, he ſays, are the only true Deiſts, but their principles, he apprehends, ſhould lead them to embrace Chriſtianity; and therefore he concludes, that there is now no conſiſtent ſcheme of Deiſm in the world. Evidence on Nat. and Rev. Religion, p. 12, 27.

The firſt Deiſtical writer of any that appeared in this country, was Herbert, baron of Cherbury. He lived and wrote in the 17th century. His book "De Veritate" was firſt publiſhed at Paris in 1624. This together with his book "De Cauſis Errorum," and his Treatiſe "De Religione Laïci," were afterwardes publiſhed in London. His celebrated work "De Religione Gentilium," was publiſhed at Amſterdam in 1663, in 4to, and in 1700 in 8vo. and an Engliſh tranſlation of it was publiſhed at London in 1705.

As he was one of the firſt that formed Deiſm into a ſyſtem, and aſſerted the ſufficiency, univerſality, and abſolute perfection of natural religion, with a view to diſcard all extraordinary revelation, as uſeleſs and needleſs, we ſhall ſubjoin the five fundamental articles of this univerſal religion. They are theſe: 1. That there is one ſupreme God. 2. That he is chiefly to be worſhipped. 3. That piety and virtue are the principal part of his worſhip. 4. That we muſt repent of our ſins; and if we do ſo, God will pardon them. 5. That there are rewards for good men, and puniſhments for bad men, both here and hereafter. Our own and the preceding age has produced a number of advocates in the ſame cauſe; and however they may have differed among themſelves, they have been agreed in their attempts of invalidating the evidence and authority of divine revelation. We might mention Hobbes, Blount, Toland, Collins, Woolſton, Tindal, Morgan, Chubb, lord Bolingbroke, Hume, &c. Some have alſo added lord Shafteſbury to the number.

But the friends of Chriſtianity have no reaſon to regret the free and unreſerved diſcuſſion which their religion has undergone. Objections have been ſtated and urged in their full force, and as fully anſwered; argument and raillery have been repelled; and the controverſy between Chriſtians and Deiſts has called forth a great number of excellent writers, who have illuſtrated both the doctrines and evidence of Chriſtianity in a manner that will ever reflect honour on their names, and be of laſting ſervice to the cauſe of genuine religion, and the beſt intereſts of mankind.

The number of Deiſts is ſaid to be daily increaſing: in England many men of ſpeculation and letters are ſaid to incline that way; and the like is obſerved in ſome of our neighbour nations, where freedom of ſpeaking, writing, and thinking, is indulged. Not that unreſtrained liberty in this reſpect can ever injure Chriſtianity, or ſerve the cauſe of Deiſm: truth neither needs nor ſeeks diſguiſe; but where freedom is allowed, men's ſentiments, on the ſubject of religion, are more generally known.

DEITY, GODHEAD, a common appellation given to God; and alſo by the poets to the heathen gods and goddeſſes.

DEIVIRILE, a term in the ſchool theology, ſignifying ſomething divine and human at the ſame time. See THEANDRIC.

The word is a compound of *Deus*, God, and *virilis*, of *vir*, man.

DEIZABAD, in *Geography* a town of Perſia in the province of Irak; 90 miles N. of Iſpahan.

DELAGOA BAY, a bay on the eaſt coaſt of Africa, ſituated in S. lat. 26°, E. long. 32°; and frequently viſited by veſſels employed in the ſouthern whale fiſhery. One of the chief rivers which enters the bay is the Mafumo; and the natives on the northern and ſouthern banks follow diſtinct cuſtoms, the men on the former wearing ſingular helmets of ſtraw. On the ſouthern ſide are 14 chiefs, ſubject to a king called Capellah, whoſe dominions extend about 200 miles inland, and about 100 on the ſea-ſhore, computed by the natives in days' journies of 20 miles each. Cattle and poultry are abundant, and may be purchaſed at a very cheap rate; the favourite articles being blue linens, old cloaths, braſs rings, copper wire, large glaſs beads, tobacco, pipes, &c.; the fiſh are numerous and excellent; and turtle is taken in

Deer iſland. The ſoil is a rich black mould, ſown with rice or maize in December or January; the dry ſeaſon laſting from April till October. There are many fruit-trees and uſeful plants, particularly the ſugar-cane; but no horſes, aſſes, nor buffaloes. The wild animals are the tiger, (panther), rhinoceros, antelope, hare, rabbit, wild hog, with Guinea hens, partridges, quails, wild geeſe, ducks, and ſome ſmall ſinging birds. The natives are Kuffees, that is, pagans, of a bright black colour, tall and ſtout, who go nearly naked, and are tattooed. They are good-humoured and harmleſs, and fond of excurſions on the river; there being what is called a king of the water, only yielding in power to Capellah. Like the reſt of Africa, the country is not populous; and Mr. White in his "Journal of a Voyage from Madras," 1800, 4to. ſuppoſes, that the inhabitants around this large bay may be from ſix to ten thouſand.

DE LA FOND, in *Biography*, a ſhallow conceited author of a treatiſe on muſic, publiſhed in 1725, octavo, under the title of "A new Syſtem of Muſic," in which he pretended to entirely new invent the art, furniſh it with new technica, and ſhorten its ſtudy three-fourths of the time uſually beſtowed on it, and alſo to teach a new and eaſier method than any yet known of figuring and playing thorough baſe, or, as he affectedly calls it, compound baſe.

DELAIRE, one of the claimants to the formula of accompanying the muſical ſcale of eight notes aſcending, and eight deſcending, commonly called by the French, *La regle de l'octave*, which ſee.

DELAKUS, in *Geography*, a ſmall town of Abyſſinia, ſituated on the top of a hill near the river Nile, W. of the lake of Dembea, in N. lat. 11° 44′. E. long. 37° 2′. It extends from N. E. to N. N. E. and is more conſiderable in appearance than the generality of the ſmall towns or villages in Abyſſinia, becauſe it is inhabited by Mahometans only, a trading, frugal, intelligent, and induſtrious people. It gives name to a ford of the river, which is paſſable from the end of October to the middle of May.

DE LA MARCH, a weſtern water of Illinois river, in the N. W. territory of America; 30 yards wide, and navigable eight or nine miles.

DELAMATTENOOS, an Indian tribe, in alliance with the Delawares.

DELANY, PATRICK, in *Biography*, a clergyman of conſiderable celebrity in Ireland, was born about the year 1686. It is not known where or under whom he received the early part of his education; but he finiſhed his ſtudies at Trinity college, Dublin. Here he became diſtinguiſhed for learning, and was elected fellow of his college. He obtained numerous pupils, and by their progreſs Mr Delany gained a high reputation. He was the friend and aſſociate of Dr. Swift, and joined him and Dr. Sheridan in a variety of poetical effuſions, in which, however, he indulged only in the hours of relaxation from his ſtudies. He cultivated the talents of a preacher, and became very popular. About the year 1724 he was involved in a diſpute with the provoſt of the college, and was obliged ſo far to ſubmit himſelf as to acknowledge he had acted with impropriety. This offence created him other enemies, and prevented him from riſing in the church. His political principles, alſo, as a tory were obſtacles to any important preferment. About the year 1727 Delany, who had already taken his degree as Dr., was preſented, by the univerſity of Dublin, to a ſmall living worth about 100*l. per ann.*: and alſo was appointed chancellor of Chriſt-church, which produced a ſimilar income. He was afterwards appointed prebend of St. Patrick's cathedral; but he had previouſly relinquiſhed the advantages and emoluments ariſing from his fellowſhip, ſo that his income was ſtill very limited. In 1729 he commenced the publication of a periodical paper, called "The Tribune," which was a work of merit, but not ſufficiently adapted to the taſte of the public to become popular or long-lived. In 1731 Dr. Delany came to London with introductory letters to Dr. Gibſon, biſhop of London: he ſubmitted to his lordſhip's judgment a theological work, entitled "Revelation examined with Candour," &c. This he afterwards publiſhed, with the approbation of the worthy prelate. It was ſo highly eſteemed at the time that it ſoon paſſed through three editions. It conſiſts of a variety of diſſertations on ſubjects, deemed at that period of conſiderable importance, but which have ſince, or at leaſt many of them, been very little attended to. During our author's abſence from Dublin he married an Iriſh widow lady of conſiderable fortune, by which he was enabled to indulge his natural generoſity, and to live in a ſtyle of hoſpitality, to which his former narrow means were wholly unequal. This fortune, however, in after-life, was the occaſion of much trouble, and expenſive law and chancery ſuits, which, though they terminated in favour of the doctor's fortune and fame, which had been virulently attacked, muſt for ſeveral years have been the ſource of great uneaſineſs. In the Biographia Britannica is a long and intereſting account of the diſpute drawn from authentic legal ſources. In 1738 Dr. Delany gave to the world one of the beſt, if not the very beſt, of his productions; it was entitled "Reflections upon Polygamy, and the Encouragement given to that Practice in the Old Teſtament." The object of the author was to point out the diſorders and miſchiefs which the practice of polygamy muſt introduce into ſociety: the arguments have generally been admitted to be ſtrong, and his reaſoning very concluſive. There have, however, we apprehend, been very few in this country, at any times, who have been advocates for the contrary opinion, and therefore the ſubject was of leſs practical importance than was ſuppoſed by the doctor and his adherents. Dr. Delany's next publication was "An hiſtorical Account of the Life and Reign of David, King of Iſrael," which, by the candid and judicious, was conſidered as too much of an eulogy on a character, which, in ſome reſpects, is expoſed to the ſeverity of animadverſion. (See DAVID.) Dr. Delany, having loſt his wife, married a ſecond time a lady of great taſte and ſkill in painting, and other ingenious arts. To this lady Dr. Kippis has devoted a ſeparate article; we may therefore in this place obſerve that Mrs. Delany excelled in embroidery and ſhell-work, and at the age of 74 ſhe invented a new and beautiful mode of exerciſing her ingenuity by the conſtruction of a Flora of a moſt ſingular kind, formed by applying coloured papers together. It conſiſted of nearly 1000 plants executed with unparalleled preciſion and truth. In the year 1744 Dr. Delany publiſhed a volume of "Sermons on the ſocial Duties;" and in another edition were added "Sermons on the oppoſite Vices." In the ſame year he was preſented with the deanery of Down, chiefly through the recommendation of the whigs, who had formerly ſet themſelves againſt his promotion in the church. In 1754 he publiſhed "Obſervations upon Lord Orrery's Remarks on the Life and Writings of Dr. Jonathan Swift, containing ſeveral ſingular Anecdotes relating to the Character and Conduct of that great Genius, and the moſt deſervedly celebrated Stella." The chief object of this work was to vindicate the dean from ſome miſrepreſentations contained in the noble lord's remarks, in which the doctor has been very ſucceſsful: he has alſo afforded a clearer view of the real character of Dr. Swift than had been given in any other publication. Our author alſo publiſhed another volume of ſermons, of which thoſe on practical ſubjects, are of real and ſterling merit. In 1763 he publiſhed the third volume of his "Revelation examined with Candour:" and in 1766 another

another volume of diſcourſes and diſſertations made their appearance. This was the laſt work publiſhed by Dr. Delany: we have not, however, enumerated all his publications; many ſingle ſermons and ſmall tracts do not appear to command ſeparate notice. The doctor died at Bath, in the month of May 1768, in the 83d year of his age. As a writer he poſſeſſed reſpectable talents, which he exerciſed in the cauſe of virtue and true religion. His piety and benevolence were conſpicuous; but the warmth of his temper was ſometimes accompanied with a certain portion of irritability and impetuoſity. Few excelled him in charity, and hoſpitality. His income which, during the laſt twenty years of his life, was 3000*l. per ann.*, ſunk under the exerciſe of theſe virtues, and he left little behind him but his books and furniture. He is ſaid to have been a very abſent man, in proof of which the following anecdote, among others, has been told of him. Being at his own deſire appointed to preach before the king, and not knowing the uſual etiquette of the buſineſs, he entered the royal chapel after ſervice was commenced; not knowing the place appropriated to the preacher, he crouded into the deſk by the reader. The veſturer in the midſt of his devotions went and pulled him by the ſleeve, but the doctor chagrined at being interrupted during the ſolemnity of prayer, reſiſted the intruder, who in vain begged him to come out; and ſaid, "There was no text:" the doctor ſaid he had a text, and it was ſome time before he could be brought to underſtand that the text muſt be written out for the cloſets. Biog. Brit.

DELARAM, in *Geography*, a town of Perſia, in the province of Segiſtan; 90 miles N. E. of Zareng.

DELAS, a river of Wales, in the county of Brecknock, which runs into the Yrvon, five miles S. W. of Bealth.

DELAS, or *Silla*, *Diala*, in *Ancient Geography*, a river of Aſia, in Perſia, to the left of the Tigris, into which it diſcharges itſelf, after having watered the towns of Apollonia, Aſtargeda, &c. in flowing from its ſource in mount Zagrus.

DE LA WAR, a town of America, in the ſtate of Virginia, and King William's county, ſituated on the broad peninſula formed by the confluence of the Pamunky and Mattapony. The united ſtream here aſſumes the name of York-river. The town lies 20 miles N. by W. of Williamſburg.

DELAWARE, one of the United States of N. America, ſituated between 38° 29′ 30″, and 39° 54′ N. latitude, and between 75° and 75° 48′ W. long., being 92 miles in length and 24 miles in breadth, and containing 2000 ſquare miles, or 1,200,000 acres. This ſtate is bounded E. by the river and bay of the ſame name, and the Atlantic ocean; on the S. by a line from Fenewick's iſland, in N. lat. 38° 29′ 30″, drawn weſt till it interſects what is commonly called the *tangent* line, dividing it from the ſtate of Maryland; on the W. by the ſaid tangent line, paſſing northward up the peninſula, till it touches the weſtern part of the territorial circle; and thence on the N. by the ſaid circle, deſcribed with a radius of 12 miles about the town of Newcaſtle, which divides this ſtate from Pennſylvania. It derived its name from Lord De La War, who was inſtrumental in eſtabliſhing the firſt ſettlement of Virginia. The Delaware ſtate is divided into three counties, viz. Newcaſtle, Kent, and Suſſex, whoſe chief towns are Wilmington, Newcaſtle, Dover, and Lewes. Dover is the ſeat of government. The number of inhabitants is 64,273, of whom 6153 are ſlaves. The eaſtern ſide of the ſtate is indented with numerous creeks, or rivers, which generally have a ſhort courſe, ſoft banks, many ſhoals, and are ſkirted with very extenſive marſhes. In the ſouthern and weſtern parts of this ſtate, ſpring the head-waters of Pocomoke, Wicomico, Nanticoke, Choptank, Cheſter, Saſſafras, and Bohemia rivers, all of which fall into Cheſapeak bay, and ſome are navigable for 20 or 30 miles into the country by veſſels of 50 or 60 tons. Excepting the upper part of the county of Newcaſtle, this ſtate is, generally ſpeaking, low and level. It abounds at particular ſeaſons of the year with ſtagnant water, which renders it unfit for the purpoſes of agriculture, and injurious to the health of its inhabitants. The ſpine, or higheſt ridge of the peninſula, runs through the ſtate of Delaware, inclining to the eaſtern or Delaware ſide. It is deſignated in Suſſex, Kent, and part of Newcaſtle, counties by a remarkable chain of ſwamps, from which the waters deſcend on each ſide, paſſing on the E. to the Delaware, and on the W. to the Cheſapeak. Notwithſtanding the ſwamps already mentioned, Delaware is an agricultural ſtate; including a fertile tract of country, which yields a variety of uſeful productions. Along the Delaware, and from eight or ten miles into the interior country, the ſoil is generally a rich clay. Thence to the ſwamps above mentioned, it is light, ſandy, and of an inferior quality. About Chriſtiana the heights are lofty; ſome of the hills of Brandywine are rough and ſtony; but with theſe and ſome few other exceptions, the lower country forms almoſt one extended plain. In the county of Newcaſtle the ſoil is a ſtrong clay; in Kent it has a conſiderable mixture of ſand; and in Suſſex the ſand predominates. Wheat of the beſt quality is cultivated in this ſtate, and it is much valued and ſought for, not only through the States of the Union, but in foreign markets. Beſides wheat, which yields the beſt ſuperfine flower, this ſtate generally produces plentiful crops of Indian corn, barley, rye, oats, flax, buckwheat, and potatoes, and various kinds of fruit in great perfection. It abounds in natural and artificial meadows containing a large variety of graſſes. Hemp, cotton, and ſilk, duly attended, would, without doubt, flouriſh here very well. The county of Suſſex has excellent grazing lands. From hence are alſo exported large quantities of lumber, obtained chiefly from an extenſive ſwamp, called the Indian river or Cypreſs ſwamp, lying partly in this ſtate, and partly in the ſtate of Maryland. This moraſs extends ſix miles from E. to W., and nearly twelve from N. to S., including an area of nearly 50,000 acres of land. It contains a great variety of plants, trees, wild beaſts, birds, and reptiles. Almoſt the whole of the foreign exports of Delaware are from Wilmington; the trade from this ſtate to Philadelphia is very conſiderable, being the principal ſource whence that city draws its ſtaple commodity. No leſs than 265,000 barrels of flour, 300,090 buſhels of wheat, 170,000 buſhels of Indian corn, beſide barley, oats, flax-ſeed, paper, ſlit iron, ſnuff, ſalted proviſions, &c. &c. to a very conſiderable amount, are annually ſent from the waters of the Delaware ſtate; of which the Chriſtiana is much the moſt productive, and probably much more ſo than any other creek or river of like magnitude in the Union; 245,000 barrels of flour, and other articles to the amount of 80,000 dollars, or more, being exported from this creek; of which to the value of 550,000 dollars are manufactured on its northern bank, within two or three miles of the navigation. Among other branches of induſtry exerciſed in or near Wilmington, are a cotton manufactory, and a bolting-cloth manufactory, both of which promiſe to be of laſting benefit to the country. In the county of Newcaſtle are ſeveral fulling mills, two ſnuff mills, a ſlitting mill, four paper mills, and 60 mills for grinding grain, all of which are turned by water; and this neighbourhood admits ſtill of greater improvements. The legiſlature in the January ſeſſion 1796 paſſed an act to create a fund for the eſtabliſhment of ſchools throughout the ſtate. The manufacture of flour is carried unto great perfection in this

ſtate; numerous mills are erected for this purpoſe; and thoſe of Brandywine ſtream, three miles from the creek on which they ſtand, half a mile from Wilmington, and 27 from Philadelphia, are moſt extolled, as capable of grinding annually 400 000 buſhels, though, from collateral circumſtances, their uſual yearly produce does not amount to more than from 290 to 300,000 buſhels. Theſe mills employ about 200 perſons; and they are ſo conveniently ſituated with regard to navigation, that a veſſel carrying 1000 buſhels of wheat may be laid along-ſide any of theſe mills, and the water adjoining ſome of them is ſufficiently deep to admit veſſels of twice the above ſize. By means of well contrived machinery the veſſels are loaded and unloaded with ſurprizing expedition. Beſides wheat and flour, this ſtate exports lumber, and various other articles. The amount of exports for the year ending September 30, 1791, was 119,878 dollars 93 cents; in 1792, 133,972 dollars 27 cents.; in 1794, 207,985 dollars 33 cents.; and in 1801, 440,504 dollars.

In the ſtate of Delaware, there is a variety of religious denominations; of Preſbyterians there are 24 churches; of Epiſcopalians, 14; of Baptiſts, 7; and of Methodiſts, a conſiderable number, particularly in the two lower counties of Kent and Suſſex. At Wilmington there is a Swediſh church, one of the oldeſt in the United States.

Of minerals there are few in this ſtate, except iron. Wheat and lumber are its ſtaple commodities. We have already mentioned ſeveral other articles of its produce and manufacture.

Settlements were made in Delaware by the Dutch about the year 1623, and by the Swedes about the year 1627. Their ſettlements were comprehended in the grant to the duke of York; and William Penn united them to his government by purchaſe. They were afterwards ſeparated, in ſome meaſure, from Pennſylvania, and denominated, the "Three Lower Counties." They had their own aſſemblies; but the governor of Pennſylvania uſed to attend, as he did in his own proper government. At the late revolution, the three counties were erected into a ſovereign ſtate, and have eſtabliſhed a republican conſtitution. Morſe.

DELAWARE *County*, a county of Pennſylvania, S.W. of Philadelphia county, on the Delaware river; about 21 miles long, and 15 broad, containing 115,200 acres, and ſubdivided into 21 townſhips, the chief of which is Cheſter. The number of inhabitants is 12,809. The lands bordering on the Delaware are low, and afford excellent meadow and paſturage; and are guarded from inundations by mounds of earth or dykes, which are ſometimes broken down by extraordinary freſhes in the river, to the great damage and ſubſequent expence of the proprietors. Great numbers of cattle are brought hither from the weſtern parts of Virginia, and N. Carolina, to be fattened for ſupplying the Philadelphia market.

DELAWARE, a county in New-York, on the head-waters of Delaware river, containing 21,700 inhabitants.

DELAWARE, a townſhip in Wayne county, Pennſylvania, including 381 inhabitants.

DELAWARE *Bay* and *River*. The bay is 60 miles long, from the cape to the entrance of the river, at Bombay Hook; occupies a ſpace of about 630,000 acres; and is in ſome parts ſo wide, that a ſhip, in the middle of it, cannot be ſeen from the land. It opens into the Atlantic N.W. and S.E. between cape Henlopen on the right, and cape May on the left. Theſe capes are 18 or 20 miles apart. Delaware river was called Chihohocki by the aboriginals, and in an old Nuremberg map is named Zuydt river. It riſes by two principal branches in the ſtate of New York; the northernmoſt of which, called the Mohawk's or Cookquago branch, riſes in lake Utſayanthe, lat. 42° 25′, and takes a S.W. courſe, and turning ſouth-eaſterly, croſſes the Pennſylvania line in lat. 42°; and about 7 miles from thence, it receives the Popachton branch from the N.E., which riſes in the Kaat's-Kill mountains. Thence it runs ſouthwardly, until it touches the N.W. corner of New Jerſey, in lat. 41° 24′; and then paſſes off to ſea through Delaware bay; having N. Jerſey E. and Pennſylvania and Delaware W. The bay and river are navigable from the ſea to the great or lower falls at Trenton, 155 miles; and are accommodated with buoys and piers for the direction and ſafety of ſhips. A 74 gun ſhip may go up to Philadelphia, 120 miles by the ſhip channel from the ſea. The diſtance acroſs the land, in a S.E. courſe to N. Jerſey coaſt, is but 60 miles. Sloops go 35 miles above Philadelphia to Trenton falls; boats, that carry 8 or 9 tons, 100 miles farther; and Indian canoes 150 miles, except ſeveral ſmall falls or portages. It is in contemplation to connect the waters of Cheſapeak bay with thoſe of Delaware river by 4 different canals, *viz.* Elk river with Chriſtiana creek; Broad creek, another branch, with Red-lion creek; Bohemia, a third branch of the Elk, with Apoquinemy creek; and Cheſter river with Duck creek. Morſe.

DELAWARE, a ſmall river of Eaſt Florida.

DELAWARE, a townſhip in the county of Suffolk, Upper Canada, lying on the E. ſide of the river Thames, in the plains above the Delaware village of Indians.

DELAWARES, an Indian nation, formerly numerous and powerful, who poſſeſſed part of Pennſylvania, New Jerſey, and New York. This name was given them by the Europeans; for they call themſelves Lennilenape, that is, Indian men; or Woapannackky, which ſignifies, a people living towards the riſing ſun. They now reſide about halfway between lake Erie and Ohio river. They are an ingenious and intelligent people; and, like the Six Nations, are celebrated for their courage, peaceable diſpoſition, and powerful alliances. Almoſt all the neighbouring nations are in league with them, eſpecially the Mahikun, Shawanees, Cherokees, Twichtwees, Wawiachtanos, Kickapees, Moſhkos, Tuckachſhas, Chippeways, Ottawas, Putiwoatamies, and Kaſkakias. The Delawares, who were hoſtile, made peace with the United States in 1795, and ceded ſome lands. The United States, on their part, have engaged to pay them in goods to the value of 1000 dollars a year for ever. Formerly the Delawares could furniſh 600 warriors; but their number has been lately conſiderably decreaſed by war. Morſe.

DELBRUCK, a ſmall town of the kingdom of Weſtphalia. It formerly belonged to the biſhopric of Paderborn; and is ſituated 12 miles W. of Paderborn.

DEL CREDERE, *Commiſſion of*, in *Commerce*, an undertaking by an inſurance-broker, for an additional premium, to inſure his principal againſt the contingency of the failure of the under-writer. 1 Term Rep. 112.

DELDEN, in *Geography*, a ſmall town of the kingdom of Holland, in the department of Overyſſel.

DELEBIO, a ſmall town of the canton of the Griſons, in the Helvetic republic, ſituated in the Veltlin, in the Squadra de Morbegno, near the caſtle of Fuentes, remarkable for the abbey of Aqua Fredda, and a chapel built on the field where Philip Maria, duke of Milan, defeated the Venetians in 1434. Dictionnaire de la Suiſſe.

DELECITO, a town of Naples, in the province of Capitanata; 10 miles S.S.E. of Troja.

DELEGATES, certain perſons delegated, or appointed by the king's commiſſion, under the great ſeal, to ſit upon

an appeal to the king in the court of chancery. See COURT *of Delegates*.

For delegates in academical cauſes; ſee *Univerſity* COURT.

DELEGATION, a commiſſion extraordinary given a judge to take cognizance of and determine ſome cauſe, which ordinarily does not come before him.

In the civil law, delegation alſo denotes a ſort of ſurrender, whereby a perſon ſubſtitutes another debtor in his place. See Ulpian, l. 11. ff. *de novationibus & delegationibus*.

This delegation differs from transferring, or tranſlation, becauſe three perſons intervene in a delegation, *viz.* the creditor, the debtor, and a third, who himſelf is indebted to the debtor, and on whom the debtor transfers the obligation he was under to pay the creditor, delegating him, as it were, for that purpoſe. But, in a ſimple transfer, it is enough the transferrer and the transferree be preſent.

DE'LE'MONT, or DELSBERG, and *Delſperg*, in *Geography*, a ſmall town of France, in the department of the Upper Rhine, chief place of a diſtrict of the ſame name, ſituated on the river Byrſe, with a population of 904 individuals. It has a ſubprefect, a court of juſtice, and a regiſter office. Its canton has an extent of 307½ kiliometres, 32 communes, and 10,118 inhabitants. The whole diſtrict comprizes 5 cantons, 107 communes, 35,779 inhabitants, and a territorial extent of 920 kiliometres. The country is mountainous, and produces very little.

Till the year 1793 Délémont belonged to the biſhopric of Baſle. The prince biſhop had a palace here, and the canons of Moutiers ſome very elegant houſes. Near Délémont are fine quarries of white free-ſtone, reſembling marble, a mineral ſpring, and other natural curioſities, but chiefly petrifications. Herbin Statiſtique de la France. Dictionnaire de la Suiſſe.

DELETERIOUS (from δηλεω, *noceo, I hurt*), a term ſometimes uſed among naturaliſts for ſuch things as are of a pernicious and poiſonous nature. See POISON.

DELF, a quarry, or mine, where ſtone or coal is dug. From the Saxon word *delfan*, to delve or dig.

DELF *of Coal*, denotes coal lying in veins under ground, before it is dug up.

DELF, or *Delve of Coals*, is alſo a certain quantity, dug out of a mine or pit. See COAL.

DELF is alſo uſed in *Heraldry* for one of the abatements of honour; being a ſquare in the middle of the eſcutcheon.

A delf tenne was anciently due to him who receded from his own challenge, or any way departed from his parole, or word. If there be two or more delfs in an eſcutcheon, it is then no longer an abatement: ſo alſo, if it be of metal, or charged upon; it then becomes a charge of perfect bearing.

DELF, or *Delft-ware*, Fr. *Fayence*, a kind of pottery of baked earth, covered with an enamel, or white glazing, which gives it the appearance and neatneſs of porcelain. The baſis of this pottery is clay; and the kinds of clay chiefly uſed are the blue and green, with an addition of marle or ſand, in order to leſſen the contraction of the clay, to render it leſs compact, and to afford a better ground for the enamel. Red clay is alſo added, which, on account of its ferruginous matter, binds and gives a greater ſolidity. The proportions of theſe ingredients vary in different works, according to the different qualities of the earths employed. Three parts of blue clay, two of red clay, and five parts of marle, form the compoſition uſed in ſeveral manufactories. Veſſels formed of theſe materials muſt be dried very gently, to avoid cracking. They are then to be placed in a furnace to receive a ſlight baking, and they are laſtly to be covered with an enamel or glazing, which is done by putting upon the veſſels thus prepared, the enamel, which has been ground very fine, and diluted with water. The glazing, which is nothing but white enamel, ought to be ſo opake as not to ſhew the ware under it. The enamels for delf-ware are compoſed of ſand or flints, vitrifying ſalts, calx of lead, and calx of tin. The vitrification of ſand is effected by ſomewhat leſs than an equal part of alkaline ſalt, or twice its weight of calx of lead, and one part of calx of tin, which is deſigned for giving a white opake colour to the maſs, is to be added to three or four parts of all the other ingredients taken together. M. D'Antic recommends for the white enamel, uſed in glazing, a mixture of a hundred pounds of calx of lead, with about a ſeventh part of that quantity of calx of tin, for common delf, or a fourth part of calx of tin for the fineſt delf; a hundred, or a hundred and ten pounds of fine ſand; and about twenty or thirty pounds of ſea-ſalt or ſalt of glaſs. To make this enamel, lead and tin are calcined together with a ſtrong fire, or the ſand is alſo to be made into a frit with the ſalt or aſhes. The whole, being well mixed and ground together, is placed under the furnace, where it is melted and vitrified during the baking of the ware. Then it is to be ground in a mill, and applied as above directed. Dict. of Chem. Eng. edit. 1777. See ENAMEL, GLAZING, and PORCELAIN.

DELFACE, FRANCIS, in *Biography*, a learned French monk, was born at Montet in Auvergne, in the year 1637. He entered upon the monaſtic life at Clermont, in 1656, where he recommended himſelf to the notice and reſpect of his ſuperiors, as well by his ſteady application, as by his talents. He was fixed on, at the inſtigation of the celebrated Arnaud, to give a new edition of the works of St. Auguſtine. To this work he applied himſelf with all diligence, and had made conſiderable preparation for the publication, when an anonymous tract, that expoſed church abuſes, came out, and was imputed to him. For this he was unjuſtly baniſhed, having, it is believed, had no concern in the offence for which he ſuffered puniſhment. The place of his exile was Lower Bretagne, where he was unable to proceed on his great work. He was ſhortly after his baniſhment called upon to preach at Breſt, on ſome public occaſion, when the veſſel in which he took his paſſage was wrecked, and he was among the number of thoſe that were drowned. This happened in October 1676, in the thirty-ninth year of his age. He was author of ſeveral works which are not intereſting to the Engliſh reader. His hiſtorical eulogy, entitled, "The Epitaph of Caſimir, King of Poland, who, after having abdicated his Crown, retired into France, and became Abbot of St. Germain de Pres," is a work of conſiderable merit. Moreri.

DELFINO, in *Geography*, a town of European Turkey, and capital of Lower Albania, where the pacha reſides; 356 miles W. of Conſtantinople, and 60 S.S.W. of Edeſſa. N. lat. 40° 4′. E. long. 21° 15′.

DELFT, or VAN DELPHUS, WILLIAM JAMES, in *Biography*, an excellent painter and engraver, was the ſon of William Delft, and a near relation (grandſon, according to Pilkington) of Michael Miravelt, and born at Delft in 1619. He drew and painted portraits with excellent taſte; and having been inſtructed by Miravelt, acquired a ſimilar mode of deſign and colouring, and ſucceſsfully imitated him in the management of his pencil, ſo that he is ſaid to have equalled Miravelt in force and delicacy. However, he is more generally known as an engraver; and his beſt prints are highly finiſhed: ſome of them are executed in a bold, powerful, open ſtyle, which produces a fine effect. Such

was his portrait of Hugo Grotius, dated 1652; and others in a neat and much more finiſhed manner, as we find, ſays Strutt, in the admirable portrait of Michael Miravelt, from a picture of Vandyck. He uſually ſigned his name at length, and ſometimes ſubſtituted the letters G. V. D., or a cypher compoſed of a G and a D. It does not appear that he was ever in England; and yet he engraved ſeveral Engliſh portraits, as Charles I. of England, Henrietta Maria, his queen, George Villars, duke of Buckingham, &c. and ſtyles himſelf the king's engraver. He died in 1661, Pilkington and Strutt.

DELFT, in Latin *Delphi*, in *Geography*, a conſiderable and handſome town of the kingdom of Holland, in the department of the Maeſe, or Meuſe, on the river Schie between Rotterdam and Leyden, 4 miles S. of the Hague, 6 miles N.W. of Rotterdam, and 9 miles S. of Leyden. N. lat. 51° 53′. It has 25,000 inhabitants, is nearly two miles in circumference, and defended againſt inundations by three dams or dikes. The principal ſtreets have ſpacious canals planted on each ſide with trees. The public buildings, particularly the town-houſe or guild-hall, are very magnificent. The arſenal, before the late revolutions, was conſidered as one of the beſt furniſhed in Holland. In the principal church is the noble tomb of prince William I. of Orange, founder of the former Batavian republic, who was baſely aſſaſſinated in 1584; and in another church a marble monument erected to the memory of admiral Tromp.

Delft owes its origin to Godfrey the Hunchback, duke of Lower Lorraine, who built a caſtle here in 1071, but it is chiefly remarkable for its manufacture of earthen ware, or pottery, made of baked earth covered with an enamel or white glazing which gives it the appearance and neatneſs of porcelain. This earthen ware is known in commerce by the name of *Delft ware*.

DELFTLAND, was formerly that portion or diſtrict of the department of the Maeſe, in Holland, in which the towns of Delft and Delftſhaven are ſituated.

DELFTSHAVEN, or the port of Delft, a ſmall neat town of the kingdom of Holland, in the department of the Maeſe, on the mouth of the river Maeſe, 6 miles S. by E. of Delft, with which it is connected by a handſome canal. It is in fact the harbour of Delft.

DELFZYL, a ſmall town of the kingdom of Holland, in the department of Groeningen, with a caſtle near the mouth of the river Eems at its confluence with the Fivel, or Damſter Diep, 3 miles N. of Dam, 18 miles N.E. of Groeningen, and 12 S.W. of Emden. N. lat. 53°. 18′. E. long. 6° 20′.

DELGADO, CAPE, a cape on the eaſt coaſt of Africa, in the Indian ſea. S. lat. 10° 5′. E. long. 40°.—Alſo, a cape on the eaſt coaſt of Africa, in the Indian ſea. N. lat. 9° 45′. E. long. 50°. 15′.

DELGOVITIA, in *Ancient Geography*, a place of Britain, marked in Antoninus's Itinerary, iter I., 20 miles from York, belonging to the Brigantes. This ſtation is generally placed by antiquarians at Wighton, or at Godmanham, a village about half a mile from it.

DELHI, or DEHLI, one of the eleven ſoubahs, or provinces, into which Acbar, during his long reign in the 11th century, divided Hindooſtan Proper; to which four more were afterwards added. It was formerly a kingdom or empire of conſiderable extent, containing ſeveral provinces or circars, and many cities and towns; but having been the ſeat of continual wars for more than 50 years, and encroached upon by numerous invaders, it is now reduced into a wretched ſtate, and its boundaries have been fluctuating and precarious, as well as very limited. The country is almoſt depopulated, and moſt of the lands are lying waſte; the wretched inhabitants not daring to provide more than the bare means of ſubſiſtence, for fear of attracting the notice of thoſe whoſe trade is pillage. Nothing but the natural fertility of the ſoil, which produces wheat, rice, millet, ſugar, indigo, pulſe, and fruits of various kinds, and the mildneſs of the climate, more temperate even than that of the neighbouring province of Agra, could have kept up any degree of population; and rendered the ſovereignty of it, at this day, worth contending for. A tract of country, which poſſeſſes every advantage that can be derived from nature, contains the moſt miſerable of inhabitants; ſuch is the dire effect of the ambition of their ſuperiors, and ſo dearly do mankind pay for it; who, miſcalculating their powers, think they can govern as much as they can conquer. The only territory remaining to the tribe of Timur or Tamerlane is a ſmall diſtrict round Delhi, together with the city itſelf (now no longer a capital), expoſed to repeated depredations, maſſacres, and famines, by the conteſts of invaders. The province has now 8 circars, ſubdivided into 232 pergunnahs. Its revenue is ſaid to be 601,615,555 dams, reckoning 320 dams equal to 1*l.* ſterling. It is moſtly in the poſſeſſion of Sindia.

DELHI, or *Dehli*, the chief town of the fore-mentioned province, was once a celebrated city, the capital of Muſſulman ſovereignty in Hindooſtan, and in more early times, the ſeat of Hindoo dominion over northern India. We firſt hear of it, as the capital of Hindooſtan, about the year 1200; and it is ſaid to have been founded by Delu about 300 years before our era, and, as Mr. Rennell thinks, ſhould properly be written "Dehly;" the Ayen Acbaree ſays, that its ancient name (in Sanſcrit) was "Inderput," or "Indraput," the houſe of Indra. As Canouge declined, Delhi roſe in reputation; and it continued the unrivalled metropolis of Hindooſtan, till the year 1398, when Timur, or Tamerlane, turned his arms towards Hindooſtan; in October he croſſed the Indus; and ſoon after his army proceeded in different diviſions to Delhi, which ſubmitted, without what may be properly termed a battle. On the 16th of December in the ſame year, it is ſaid, that this mercileſs conqueror entered the city, erected the great ſtandard of the Tartarian empire immediately on its walls; and the uſurper, ſeated on the throne of India, in all the pride of conqueſt, received the proſtrate homage of the nobility of both nations. In conſequence of ſome reſiſtance reluctantly made by the inhabitants to the wanton ravages of their conquerors, Delhi, and all the wonderful monuments of art contained in it, were devoted to be pillaged; and on the 13th of January, this great city was deſtroyed. Delhi, however, recovered part of its former ſplendour under the dynaſty of ſuceeding kings, and was ſtill conſidered as the imperial city of Hindooſtan until the reign of Acbar, or Akbar, who, commencing his reign in 1556, and fixing his reſidence at Agra, where he died in 1605, completed the ruin which time and neglect had united to ſpread through the wide circumference, and amid the deſolated towns of Delhi. In 1647, Shah-Jehan, grandſon of Acbar, removed the ſeat of his empire from Agra to Delhi, calling it "Shahjehanabad," or "Jehannabad;" where on the banks of the river Chun he built a noble caſtle and palace, with gardens and other conveniences, which coſt above 50 lacks of rupees, or 625,000*l.* At this time the yearly revenue of Delhi amounted to 100 krores of dams, or (reckoning each dam at the 40th part of a rupee, and the rupee as 2*s.* 6*d.* ſterling) 3,125,000*l.* Aurungzebe, the third ſon of Shah-Jehan, took poſſeſſion of the throne in 1659; and during his reign the revenues of the province of Delhi amounted to 1,221,950,137 dams. Delhi

continued

continued to increaſe in ſplendour and importance, until it was entered in 1738-9 by Nadir Shah, the uſurper of the Perſian throne, who demanded 30 millions ſterling, by way of ranſom. Tumults, maſſacres, and famine were the reſult; 100,000 of the inhabitants were ſlaughtered, and 62 millions of plunder were ſaid to be collected. It was again plundered and depopulated by Ahmed Abdalla in 1756, 1759, and 1760; although during the time of Aurungzebe, it was ſuppoſed to contain two millions of ſouls. Abdalla on this occaſion became emperor of Delhi; and if his inclinations had led him to eſtabliſh himſelf in Hindooſtan, it is probable that he might have begun a new dynaſty of emperors in his own perſon. Shah-Aulum, the lineal deſcendant of the houſe of Timur, aſpired to poſſeſs the capital city of his anceſtors, and with this view put himſelf into the hands of the Mahrattas, who promiſed to ſeat him on the throne of Delhi. Thus deluded, he left Allahabad, where he reſided under the protection of the Engliſh, to whom he owed all that he poſſeſſed, and went to Delhi, where he remained a kind of ſtate-priſoner. The private diſtreſſes of this prince, for it would be almoſt mockery to call him the great Mogul, or emperor, were ſo great, that in 1784 his ſon was deputed to ſolicit aſſiſtance from the Engliſh. Since the peace of 1782, Madajee Sindia, a Mahratta chief, and the poſſeſſor of the principal part of Malwa, has taken the lead at Delhi, and taken poſſeſſion of ſeveral places, with a view to extend his conqueſts on the ſide of Agimere, and to eſtabliſh a conſiderable ſtate or kingdom.

Delhi is not ſo well built as Agra. It is not eaſy to aſcertain its extent, which was ſaid to contain, as we have above mentioned, two millions of inhabitants. Bernier, a reſpectable and credible writer, who penned his account in 1663, only four years after the acceſſion of Aurungzebe, does not warrant ſo high a calculation of its inhabitants; and it is well known that, under his reign, both the empire and capital were greatly augmented. Bernier eſtimated the circumference of Delhi at 3 leagues only, reckoning what was within the fortifications, beſides which he deſcribes ſeveral ſuburbs, but altogether, no extraordinary extent for a capital city in India. He deſcribes Agra as being conſiderably larger. After the plunders and maſſacres which it has undergone, ſince the decline and downfall of the Mogul empire, it muſt be ſuppoſed to have been reduced very low; and accordingly, it is ſpoken of by late travellers as a city of moderate extent; and even for an Indian city, very ill built. Claud Boudier found the latitude of Delhi to be 28° 37′, and its longitude 77° 40′. The account from which we ſhall make the following extracts is the lateſt we have ſeen, and we have no reaſon to queſtion its accuracy. It is extracted from a journal of obſervations made during an official tour through the Dowab and the adjacent diſtricts, by lieutenant W. Franklin, in company with captain Reynolds of the Bombay eſtabliſhment, appointed by the Bengal government to ſurvey that part of the country in the year 1793. (Aſiatic Reſearches, vol. iv. p. 417, &c.) The extent of the ruins of old Delhi cannot, as this writer ſuppoſes, be leſs than a circumference of 20 miles. The environs to the N.W. are crowded with the remains of ſpacious gardens and country-houſes of the nobility, which were formerly ſupplied with abundance of water by means of the noble canal dug by Ali Mirdan Khan, and which formerly extended from above Paniput quite down to Delhi, where it joined the Jumna; fertilizing in its courſe a tract of more than 90 miles in length, and beſtowing affluence on thoſe who lived within its extent. The new city of Shah-Jehanabad, built by Shah-Jehan, A.D. 1631-2, lies on the weſtern bank of the Jumna, in N. lat. 28° 36′. The city is about 7 miles in circumference and is ſurrounded on three ſides by a wall of brick and ſtone; a parapet runs along the whole, with loop-holes for muſquetry; but no cannon are planted on the ramparts. The city has 7 gates, *viz.* Lahore-gate, Ajmere-gate, Turkoman-gate, Delhi-gate, Moor-gate, Cabul-gate, and Caſhmere-gate; all of which are built of ſtone, and have handſome arched entrances of ſtone, where the guards of the city keep watch. Near the Ajmere gate is a "Madriſſa," or college, erected by the nephew of Nizam-ul-Moolluch; it is built of red ſtone, and ſituated at the centre of a ſpacious quadrangle, with a ſtone fountain. At the upper end of the area is a handſome moſque built of red ſtone, inlaid with white marble. The apartments for the ſtudents are on the ſides of the ſquare, divided into ſeparate chambers, which are ſmall but commodious. The tomb of Ghazi, its founder, is in the corner of the ſquare, ſurrounded by a ſhrine of white marble, pierced with lattice-work. The college is now ſhut up, and deſtitute of inhabitants. In the neighbourhood of the Cabul-gate is a garden, in which are two tombs, one of the wife of the emperor Mahommed Shah, and another of the daughter of Aurungzebe. On a riſing ground near this garden, whence there is a fine view of Shah-Jehanabad, are two broken columns of brown granate, 8 feet high, and 2½ feet broad, on which are inſcriptions in an ancient character.

Within the city of New Delhi are the remains of many ſplendid palaces, belonging to the great Omrahs of the empire; all of which are ſurrounded with high walls, and occupy a conſiderable ſpace of ground. Their entrances are through lofty arched gate-ways of brick and ſtone, at the top of which are the galleries for muſic; before each is a ſpacious court-yard for the elephants, horſes, and attendants of the viſitors. Each palace has likewiſe a "Mahal," or ſeraglio, adjoining, which is ſeparated from the "Dewan-Khana," by a partition-wall, and communicates by means of private paſſages. All of them had gardens with capacious ſtone-reſervoirs, and fountains in the centre; an ample terrace extended round the whole of each palace; and within the walls were houſes and apartments for ſervants and followers of every deſcription, beſides ſtabling for horſes and other accommodations. Each palace was likewiſe provided with a handſome ſet of baths, ſome of which were furniſhed with beautiful rooms, paved and lined with white marble, and conſiſting of five diſtinct apartments, into which light is admitted by glazed windows at the top of the domes.

Shah Jehànabad is alſo adorned with many fine moſques, ſeveral of which are ſtill in perfect repair and beauty. One of thoſe that are moſt worthy of notice is the "Jama Muſjed," or great cathedral, ſituated about a quarter of a mile from the royal palace, the aſcent of which, as it is ſituated on a rocky eminence, is by a flight of 35 ſtone ſteps, through a handſome gate-way of red ſtone. The doors of this gate-way are covered throughout with plates of wrought braſs, imagined by Mr. Bernier to be copper. The terrace on which the moſque is ſituated, is a ſquare of about 1400 yards of red ſtone; in the centre is a fountain lined with marble, for the purpoſe of performing the neceſſary ablutions previous to prayer. An arched colonnade of red ſtone ſurrounds the whole terrace, which is adorned with octagon pavilions at convenient diſtances, accommodated with ſeats. The moſque is of an oblong form, 261 feet long, ſurrounded at the top, with three magnificent domes of white marble, interſected by black ſtripes, and flanked by two minarets of black marble and red ſtone alternately, riſing to the height of 130 feet. Each of theſe minarets has three projecting galleries of white marble; and their ſummits are crowned with light octagon pavilions of the ſame. The whole front is faced with large ſlabs of beautiful white marble; and along the cornice are 10 compartments, 4 feet long, and 2½ broad,

inlaid with inſcriptions in black marble, in the "Nuſki," character, which are ſaid to contain great part, if not the whole, of the Koran. The inſide of the moſque is paved with flags of white marble, decorated with a black border. The walls and roof are lined with plain white marble; and the "nimber," or pulpit, is of marble, having an aſcent of four ſteps and balluſtraded. The aſcent to the minarets is by a winding ſtair-caſe of 130 ſteps of red ſtone; and at the top is a noble and extenſive view. The domes are crowned with culliſes, richly gilt; and preſenting a glittering appearance at a diſtance. This moſque was begun by Shah Jehan, in the 4th year of his reign, and completed in the tenth; the expences of its erection amounted to 10 lacks of rupees; and it is in every reſpect worthy of being the grand cathedral of the empire of Hindooſtan. Beſides the moſque above deſcribed, there are in the city and its environs above 40 others, of inferior ſize and of the ſame faſhion.

The modern city of Shah Jehanabad is rebuilt, and contains many good houſes, chiefly of brick. The ſtreets are in general narrow; but there were formerly two very noble ſtreets, one in a direction N. and S., and another lying E. and W.; the former having handſome houſes on each ſide of the way, and merchants' ſhops well furniſhed with the richeſt articles of all kinds, and provided with water by means of an aqueduct of red ſtone, conſtructed by Shah Jehan. The bazars in Delhi are at preſent but indifferently furniſhed, and the population of the city has been of late years much reduced. Cotton cloths are ſtill manufactured, and the inhabitants export indigo. Their chief imports are by means of the northern caravans, which arrive once a-year, and bring with them from Cabul and Caſhmere ſhawls, fruit, and horſes. There is alſo a manufacture at Delhi for beedree hooka bottoms. The cultivation about the city is principally on the banks of the Jumna, where it is very good; the vicinity produces corn and rice, millet and indigo. The limes are very large and fine. Precious ſtones are likewiſe to be had at Delhi, of very good quality; particularly the large red and black cornelians. The city is divided into 36 mohauls or quarters, each of which is named either after the particular Omrah who reſided there, or from ſome local circumſtances relative to the place. The modern city of Shah Jehanabad appears to have been built upon two rocky eminences; the one where the "Jama Musjid" is ſituated, named "Jujula Pahar," and the other the quarter of the oil-ſellers, called "Bejula Pahar;" both of theſe eminences afford a commanding view of the remainder of the city. From the vaſt quantity of buildings, found in the environs of Delhi for upwards of 20 miles in extent, as well as from their grandeur and ſtyle of architecture, we may infer that this had once been a rich, flouriſhing, and populous city. The palace of the royal family of Timur was erected by the emperor Shah Jehan, when he finiſhed the new city; it is ſituated on the weſtern bank of the Jumna, and ſurrounded on three ſides by a wall of red ſtone. Its circumference is about a mile, and comprehends ſeveral public buildings, particularly two halls of audience, one called "Dewaun Aum," for people of all deſcriptions, and the other, or "Dewaun Khaſs," for the nobility. The latter was formerly adorned with exceſſive magnificence; but it has in later times been much deſpoiled by invaders. It is about 150 feet in length, by 40 in breadth, and ſtill poſſeſſes many remains of beauty and ſplendour which excite admiration. Around its interior, in the cornice, are the following lines, engraved in letters of gold upon a white marble ground; "If there be a paradiſe upon earth, this is it:—'tis this, 'tis this." The royal baths, built by Shah Jehan, are ſituated to the northward of the Dewaun Khaſs, and conſiſt of three very large apartments ſurmounted by white marble domes, and admirably finiſhed within. The light is admitted from the roof by windows of party-coloured glaſſes. In the "Shah Baug," or royal gardens, is a very large octagon room, which looks towards the river Jumna.

The "Gentur Munter," or obſervatory, in the vicinity of Delhi, was built in the third year of the reign of Mohammed Shah, by the rajah Jeyſing, who was aſſiſted by many perſons celebrated for their knowledge in aſtronomy from Perſia, India, and Europe; it has been ſince plundered by the Jeits under Juwaher Sing. The royal gardens of Shalimar, began by the emperor Shah Jehan in the 4th year of his reign, and finiſhed in the thirteenth, were laid out with admirable taſte, and coſt the enormous ſum of a million ſterling; but they have ſince been laid waſte, and the greateſt part of the coſtly materials have been removed. Here are found among other buildings the apartments of the Haram, encloſed by high walls; ſome of theſe apartments are conſtructed with red ſtone, and others with brick faced with fine chunam, and decorated with paintings of flowers of various patterns. All of them have winding paſſages, which communicate with each other, and the adjoining gardens by private doors. The extent of the gardens is not above a mile in circumference, encompaſſed by a high brick wall, deſtroyed in many parts of it; and the extremities are flanked with octagon pavilions of red ſtone. They ſtill abound with old trees of a very large ſize. The proſpect to the ſouthward of Shalimar towards Delhi, as far as the eye can reach, is covered with the remains of extenſive gardens, pavilions, moſques, and burying places, all deſolate and in ruins. The environs of this once magnificent and celebrated city appear now nothing more than a ſhapeleſs heap of ruins; and the country round about is equally forlorn.

Delhi, a town of America, in the county of Delaware, and ſtate of New York, containing 820 inhabitants.

DELIA, Δηλια, in *Antiquity*, a quinquennial feſtival in the iſland of Delos, inſtituted by Theſeus when, upon his return from Crete, he placed in the temple the ſtatue of Venus, given him by Ariadne.

Delia, feaſts celebrated by the Athenians, in honour of Apollo, ſurnamed *Deliús*.

The principal ceremony in this feaſt was an embaſſy, or rather a pilgrimage, to Apollo of Delos, performed every five years by a certain number of citizens, deputed for that purpoſe, and called *Deliaſtæ*, Δηλιασται, or *Theori*, Θεωροι, *q. d.* the *ſeers*, and the firſt perſon of the embaſſy, or deputation, *Architheorus*, Αρχιθεωρος. To him were added four more of the family of the *Ceryci*, prieſts deſcended from Mercury, who reſided all the year at Delos, to aſſiſt in the temple. The whole deputation ſet out in five veſſels, carrying with them every thing neceſſary for the feaſt, and the ſacrifices.

The Deliaſts, who went abroad, were crowned with laurel. At their arrival, they immediately offered a ſacrifice to Apollo: and, after the ſacrifice, a number of young maids danced round the altar, a dance called in Greek γερανος, wherein, by their various motions and directions, they repreſented the turnings and windings of a labyrinth. When the Deliaſts returned to Athens, the people went out to meet them, and received them with all the joy and acclamation imaginable. They never laid aſide their crown till their commiſſion was fully completed; and then they conſecrated it to ſome god in his temple.

The whole time of their going and returning, with all the ceremonies of their embaſſy, was called the Delia; during which time no criminal might be executed, which was a peculiar privilege of this feaſt, not allowed to any other, not even thoſe of Jupiter. Thus, Plutarch obſerves, that it was a day conſecrated to Jupiter, when Phocion was made to take

take the poiſon to which he was condemned; whereas they waited thirty days to give it to Socrates, by reaſon of the Delia.

According to Thucydides, the Delia were firſt inſtituted in the ſixth year of the Peloponneſian war, againſt the Athenians, who had extirpated the iſle of Delos, removed all the tombs out of it, and ordained that nobody ſhould either be born or die in it; but that all the ſick people ſhould be removed into a little iſland called Rhenia; though the Ionians, and the neighbouring iſlanders of Ionia, had long before that time held a ſort of Delia; that is, feaſts and games, like thoſe which the Athenians celebrated afterwards.

DELIAC, Deliacus, among the *Ancients*, denoted a poulterer, or a perſon who ſold fowls, fatted capons, &c.

The traders in this way were called Deliaci; the people of the iſle of Delos firſt practiſed this occupation. They alſo ſold eggs, as appears from Cicero, in his Academic Queſtions, lib. iv. Pliny, lib. x. cap. 30. and Columella, lib. viii. cap. 8. likewiſe mention the Deliaci.

DELIACAL Problem, *Problema Deliacum*, a famous problem among the ancients, concerning the duplication of the cube. See Duplication *of the Cube*.

DELIAN Games, games eſtabliſhed at Delos, anterior to the Olympic games, concerning which Homer is ſilent. Thucydides (lib. iii. cap. 104.) tells us, that in very remote antiquity, there were "Games of bodily exerciſe, and of muſic, in which cities exhibited their reſpective choruſes;" and, in teſtimony of this, he quotes the following verſes from Homer's hymn to Apollo:

"To thee, O Phœbus, moſt the Delian iſle
Gives cordial joy, excites the pleaſing ſmile;
When gay Ionians flock around thy fane;
Men, women, children, a reſplendent train,
Whoſe flowing garments ſweep the ſacred pile,
Whoſe grateful concourſe gladdens all the iſle,
Where champions fight, where dancers beat the ground,
Where chearful muſic echoes all around,
Thy feaſt to honour and thy praiſe to ſound."

"That there was alſo," continues Thucydides, "a muſical game, to which artiſts reſorted to make trials of ſkill, Homer fully ſhews in other verſes to be found in the ſame hymn: for having ſung the Delian chorus of females, he cloſes their praiſe with theſe lines, in which he makes ſome mention of himſelf;

"Hail! great Apollo, radiant god of day!
Hail! Cynthia, goddeſs of the lunar ſway!
Henceforth on me propitious ſmile! and you,
Ye blooming beauties of the iſle, adieu!
When future gueſts ſhall reach your happy ſhore,
And refug'd here from toils, lament no more;
When ſocial talk the mind unbending chears,
And this demand ſhall greet your friendly ears—
Who was the bard, e'er landed on your coaſt,
That ſung the ſweeteſt, and that pleaſed you moſt?—
With voice united, all ye blooming fair,
Join in your anſwer, and for me declare;
Say—the blind bard the ſweeteſt notes may boaſt,
He lives at Chios and he pleaſ'd us moſt."

Smith's Thucydides.

We cannot help pointing out another circumſtance in this hymn, which is really curious, as it implies the cultivation of a talent for imitation, at a time when ſimplicity and original genius ſeem moſt likely to have ſubſiſted, pure and untainted, by ludicrous ſimilitudes.

Homer, in verſe 162, deſcribing the employment of the Delian prieſteſſes, or nuns of the order of ſaint Apollo of Delos, tells us, that they were great adepts in the art of mimicry; and that part of the entertainment which they afforded to the numerous people of different nations, who formed their congregation, was, as the poet expreſſes it, from their being ſkilled to imitate the voices and the pulſation, (Κρεμβαλιαζειν, ſtrepitum,) or meaſure, of all nations; and ſo exactly was their ſong adapted, that every man would think he himſelf was ſinging. By the expreſſion παντων ἀνθρωπων φωνας, literally, the voices of all men, is hardly meant that theſe ladies were in poſſeſſion of the talent of *taking off* individuals, like ſome of our comedians. Φωνας ſeems only to imply national melody, or at moſt national dialects, and inflexions of ſpeech; and κρεμβαλιασυς, national rhythm, which, in all probability, was the moſt ſtriking characteriſtic in thoſe early ages of muſic.

Homer ſeems to ſketch out the order of the performance in theſe old pagan conſervatorios, v. 158; firſt they ſung a hymn in praiſe of Apollo; then another in praiſe of Latona and Diana; then they deſcended to the celebration of human heroes and heroines of ancient times; and it ſeems to have been in this part of their performance that they exerted their mimetic powers, and charmed the nations. (Θελγεσι δε φυλ' ἀνθρωπων.)

DELIAS, Δηλιας, in *Antiquity*, the name of the ſhip in which the Delian proceſſion was annually made by the Athenians. See Delia.

DELIBACHES, formed of the Turkiſh *deli*, ſignifying mad, and denoting *mad-headed*, or Deles, in the *Military Language* of the Ottoman empire, are a corps of volunteers on horſeback in the ſervice of the pachas. Theſe ſoldiers are brave, determined, enterpriſing, and ever ready to execute the orders of their maſter in the expeditions which he commands, and in the extortions which he directs. They follow him in war, perform the office of light troops, and fight without order and without diſcipline; they ſtop and bring back to battle the runaways, and frequently precipitate themſelves into the enemy's ranks, with a boldneſs which aſtoniſhes, and which ſometimes determines the victory in their favour. When a pacha is diſgraced, or when, from any motive, he diſmiſſes his delibaches, as they are without pay, and without reſources, they then commit the moſt terrible robberies; they ſpread themſelves over the fields, the villages, and even the towns; they rob indiſcriminately, lay all under contribution, and ſtop and plunder the caravans, till they are called into the ſervice of ſome other pacha, or till ſome impoſing force has put them to flight and diſperſed them.

DELIBAMENTA, in *Antiquity*, a libation offered to the infernal gods, which was always poured downwards; hence this act was expreſſed by the word *defundere*.

DELIBERATION is a voluntary operation of the mind that is employed about what we are to do or to forbear. Every man knows, ſays Dr. Reid, (Eſſays on the active Powers of Man, p. 82.) that it is in his power to deliberate or not to deliberate about any part of his conduct; to deliberate for a longer or ſhorter time, more careleſsly or more ſeriouſly; and when he has reaſon to ſuſpect that his affection may bias his judgment, he may either honeſtly uſe the beſt means in his power to form an impartial judgment, or he may yield to his bias, and only ſeek arguments to juſtify what his inclination leads him to do. In all theſe points, he determines, he wills, the right or the wrong. The general rules of deliberation ſeem, in the abſtract, perfectly evident, and form a kind of axioms in morals. They are ſuch as theſe. We ought not to deliberate in caſes that are perfectly clear. No man deliberates whether he ought to

chuſe happineſs or miſery. No honeſt man deliberates whether he ſhall ſteal his neighbour's property. When the caſe is not clear, when it is of importance, and when there is time for deliberation, we ought to deliberate with more or leſs care, in proportion to the importance of the action. In deliberation we ought to weigh things in an even balance, and to allow to every conſideration the weight, which, in ſober judgment, we think it ought to have, and no more. This is to deliberate impartially. Our deliberation ſhould be brought to an iſſue in due time, ſo that we may not loſe the opportunity of acting while we deliberate. It is not eaſy, however, to obſerve theſe ſelf-evident rules of deliberation. Our appetites, affections, and paſſions oppoſe all deliberation, but that which is employed in finding the means of their gratification, and under the influence of theſe, we may counteract and tranſgreſs thoſe maxims which reaſon approves. What is commonly called a fault of ignorance, is always owing to the want of due deliberation. The natural conſequence of deliberation with regard to any part of our conduct, is a determination how we ſhall act. When the opportunity is preſent, the determination to act is immediately followed by the action; or otherwiſe, when it is at a diſtance. In this latter caſe, the third operation of the mind called voluntary, (the firſt being ATTENTION, which ſee,) occurs, *viz.* a fixed purpoſe or reſolution, with regard to our future conduct; and ſuch a fixed purpoſe to do, ſome time hence, ſomething which we believe ſhall then be in our power, is ſtrictly and properly a determination of will, no leſs than a determination to do it inſtantly. Every definition of volition agrees to it. See VOLITION.

DELIBERATIVE, is applied to that kind, or branch, of *Rhetoric* employed in proving a thing, or convincing an aſſembly thereof, in order to oblige them to put it in execution. The deliberative kind was much in vogue among the Greeks and Romans, when the orators harangued the people.

The deliberative orations conſtitute one of the three kinds into which the ancients divided all orations; the other two are the *demonſtrative* and *judicial*. The ſcope of the deliberative was to adviſe or to diſſuade; and this kind of oration was employed in matters of public concern, agitated in the ſenate, or before the aſſemblies of the people. The ſubjects belonging to this kind of oration are taken from the nature and circumſtances of the thing itſelf under conſideration. Diſcourſes of the reaſoning kind muſt have been almoſt coëval with men's intercourſe with one another; as they no ſooner began to engage in mutual converſation, than they deliberated upon their common intereſt, and offered their advice to each other. The early practice of this mode of diſcourſe appears from ſacred writ, where we find, that when Moſes was ordered upon an embaſſy into Egypt, he would have excuſed himſelf for want of eloquence. (Exod. iv. 10.) And Homer (Il. β. 87.) repreſents the Greeks at the ſiege of Troy, as flocking like a ſwarm of bees to hear their generals harangue them. Nor is this ſpecies of oratory leſs conſpicuous for its uſefulneſs to mankind, than for its antiquity; being highly beneficial in councils, camps, or any ſocieties of men. Diſcourſes of the deliberative kind comprehend things public or private, ſacred or civil; and their chief end is either profit or intereſt; and as nothing is truly profitable that is not in ſome reſpect or other good, what is good and beneficial, as well as juſt and honourable, is the end here propoſed. The principal heads of this kind of deliberative diſcourſes, deducible from the nature and properties of the ſubject under conſideration, are ſuch as follow. *Pleaſure* often affords a cogent argument in ſuch diſcourſes, and it furniſhes an argument that has great influence on mankind in general. Quintilian, however, obſerves that pleaſure ought not to be propoſed as a fit motive of action in ſerious diſcourſes abſtractedly conſidered, and unleſs it is deſigned to recommend ſomething that is uſeful. Thus Cicero (Pro Archia, c. 7.) recommends ſtudy from the pleaſure which attends it: "If pleaſure only," ſays he, "was propoſed by theſe ſtudies," (referring to the purſuit of polite literature,) "you would think them an entertainment becoming a man of ſenſe, and a gentleman. For other purſuits neither agree with all times, all ages, nor all places; but theſe ſtudies improve youth, delight old age, adorn proſperity, afford a refuge and comfort in adverſity, divert us at home, are no hindrance abroad, ſleep, travel, and retire with us in the country." *Profit* or advantage, when it reſpects things truly valuable, is alſo a very juſt and laudable motive. *Honour* will ſupply another argument, that will have great influence in inſpiring generous minds with ardour. Virgil (Æn. l. ii. v. 289.) has very beautifully deſcribed Hector's ghoſt appearing to Æneas, in the night when Troy was taken, and adviſing him to depart, from this motive of honour:

"O goddeſs-born, eſcape by timely flight
The flames and horrors of this fatal night.
The foes already have poſſeſs'd the wall,
Troy nods from high, and totters to her fall.
Enough is paid to Priam's royal name;
More than enough to duty and to fame.
If by a mortal's hand my father's throne
Could be defended, 'twas by mine alone."

It is poſſible, however, that the expediency of undertaking any thing which, in itſelf conſidered, appears beneficial, may be queſtionable; and in this caſe the circumſtances that attend it will afford proper arguments for engaging in it. Accordingly, one of theſe is the *poſſibility* of ſucceeding. Thus, Hannibal endeavoured to convince king Antiochus, that it was poſſible for him to conquer the Romans, if he made Italy the ſeat of the war; by obſerving to him, not only that the Gauls had formerly deſtroyed their city, but that he had himſelf defeated them in every battle he fought with them in that country. (Juſtin, lib. xxxi. c. 5.) Moreover, an argument founded on *probability* will be ſtill more likely to prevail. Hence Cicero, after the fatal battle at Pharſalia, diſſuades thoſe of Pompey's party, with whom he was engaged, from continuing the war any longer againſt Cæſar; becauſe it was highly improbable after ſuch a defeat, by which their main ſtrength was broken, that they ſhould be able to ſtand their ground, or meet with better ſucceſs than they had before. (Ad. Fam. lib. vii. ep. 3.) When the poſſibility and probability of an event fail in ſupplying ſufficient motives for the proſecution of it, and a view of real or apprehended difficulties diſcourages, it may be neceſſary to recur to another argument deduced from the *facility* of accompliſhing the propoſed object. By this argument Cicero (Philipp. iv. c. 5.) encourages the Roman citizens in oppoſing Mark Antony (who, upon the death of Cæſar, had aſſumed an arbitrary power) by repreſenting to them, that his circumſtances were then deſperate, and that he might eaſily be vanquiſhed. Again the plea of *neceſſity* will give new force to the motive urged in favour of any undertaking; and therefore Cicero joins this argument with the former, to prevail with the Roman citizens to oppoſe Antony, by telling them, that "the conſideration before them was not in what circumſtances they ſhould live; but whether they ſhould live at all, or die with ignominy and diſgrace." To theſe heads may be added the conſideration of the *event*, which in ſome caſes carries great weight with it.

Cicero, in his oration for the Manilian law, uſes three of the arguments above ſtated; reaſoning from the topics of neceſſity,

the bottom of the veſſel, the particles of hot water which come firſt in contact with it, are cooled, and are rendered ſpecifically heavier, in conſequence of which they remain in their place, and no motion will take place within the water; hence the ice is not melted nearly ſo readily as in the former ſituation. Now count Rumford contends that it is by means of the above-mentioned motion only that heat is propagated through fluids, and not otherwiſe. This concluſion was no ſooner publiſhed to the ſcientific world, than it was oppoſed in an able manner by very ſkilful philoſophers. See Dalton's paper. Nich. Journ. vol. iv. p. 75. Traill's paper, ibid. for 1805, p. 133: and Murray's paper, ibid. vol. i. From theſe papers we ſhall make the following abridged extracts, which ſeem neceſſary for the elucidation of the ſubject; and in the firſt place we ſhall ſtate Mr. Murray's experiments.

Into a glaſs cylindrical veſſel water was poured, till it covered the bulb of a thermometer; its temperature was 46°, which was likewiſe the temperature of the air of the room. One ounce of olive oil, heated to 140°, was poured on a ſmall piece of cord, ſuſpended on the ſurface of the water, and the cord was ſlowly withdrawn. Any motion of the water was thus avoided. In the courſe of a minute the thermometer began to riſe ſlowly; in five minutes from the commencement of the experiment, it had riſen 4°, in ten minutes $6\frac{1}{2}$°, in fifteen minutes 8°. It then became ſtationary, and continued ſo for ſeven minutes, before it began to fall. Its deſcent was ſlow. This experiment was repeated with a hot metallic ball (inſtead of oil) immerſed in the water above the thermometer, and it was attended with a ſimilar effect.

From theſe reſults the concluſion might ſeem juſt, that the fluid muſt poſſeſs a conducting power. Yet this is rendered doubtful by the circumſtance, that in all experiments of this kind, a quantity of caloric muſt be conveyed by the ſides of the veſſel. In order to avoid this ſource of error, Mr. Murray employed a veſſel of ice. But water could not be uſed in this caſe, becauſe that fluid expands from 40° to 32°; therefore oil and mercury were uſed.

A quantity of almond oil was poured into the ice veſſel, ſo as to cover the bulb of the thermometer a quarter of an inch. A ſmall cylindrical iron cup, two inches in diameter, and having a flat bottom, capable of holding two ounces by meaſure, was ſuſpended ſo as merely to touch the ſurface of the oil, and was filled with boiling water. At the beginning of the experiment, the thermometer ſtood at 32°. In a minute and a half it had riſen to $32\frac{3}{4}$°, in three minutes to $34\frac{1}{2}$°, in five minutes to $36\frac{1}{4}$°, in ſeven minutes to $37\frac{1}{2}$°. At this point it became ſtationary, having riſen $5\frac{1}{2}$° in ſeven minutes. The temperature of the water in the cup had in this time fallen to 96°. The thermometer, after remaining ſtationary at $37\frac{1}{2}$° for ſix minutes, began to fall, and it continued to deſcend at the rate nearly of a degree in a minute and a half, till it returned to 32°. The experiment was repeated with this variation, *viz.* that the thermometer was placed lower, ſo that half an inch of oil ſtood over its bulb. It was alſo repeated with mercury inſtead of oil. But in both caſes the reſults were ſimilar to that of the firſt experiment.

"This riſe," Mr. Murray ſays, "it appears to me impoſſible to aſcribe to any other cauſe than to a power in the fluid to conduct caloric. Thus it is evident, that the ſides of the veſſel could not convey to the fluid in contact with the bulb of the thermometer any part of the caloric it received. Ice, in common with any other ſolid, may, at temperatures below its melting point, conduct caloric; but as it cannot poſſibly exiſt with a temperature above 32°, it cannot communicate any temperature above that to a fluid in contact with it, and conſequently it could not contribute in the above experiment to raiſe the thermometer above that temperature. Caloric does not radiate through tranſparent fluids; and it cannot even be ſuppoſed capable of paſſing by radiation through an opaque fluid as mercury.

If it be proved that oil and mercury are capable of conducting caloric, it will be admitted as ſufficiently probable, that other fluids may have a ſimilar power. Of theſe two, mercury, it is probable from theſe experiments, is the beſt conductor, as the riſe of the thermometer took place in it much more rapidly than in the oil."

Dr. Traill's experiments for aſcertaining the conducting powers of divers fluids, were performed in the following manner.

A cylindrical veſſel was turned out of wood, having its ſides half an inch thick, its height four inches and its diameter two. It has a moveable wooden top or cover, perforated with a hole in its centre, a little more than an inch in diameter, into which an iron cylinder, of one inch in diameter, could be eaſily introduced. This cylinder is ſupported by a ſlight flanch, or ſhoulder-piece, and can be taken up by means of a ſtring attached to its top. When the iron bar is in its place, its flat lower extremity is half an inch diſtant from the bulb of a delicate mercurial thermometer, which is fixed by wax in a hole perforating the cylinder near its bottom. This thermometer is bent to a right angle, ſo that its bulb and part of its ſtem lie in the axis of the wooden cylinder. This ſhape was preferred, becauſe the ſtem could be little affected by the caloric tranſmitted by the ſides of the veſſel, till after the bulb was acted on by the caloric of the iron bar.

A variety of experiments was performed with this apparatus in the following manner: The temperature of the room being ſteadily 67°, Fahren. therm.; during the trials, a kettle of water was kept boiling over the fire. Its temperature was between 211° and 212°, and in this the cylinder of iron was ſuffered to remain, at each experiment, for fifteen minutes. The liquid to be examined, and all the apparatus (but the iron bar) were at each experiment aſcertained to be at 67°. The liquid was poured into the wooden veſſel, till it could riſe $\frac{1}{10}$ of an inch on the ſide of the iron cylinder when in its place. The wooden top was put on, and the iron was drawn out of the kettle of boiling water by means of the attached ſtring, and inſtantly let down through the hole of the cover. The time the thermometer took to riſe through 3° (*viz.* from 67° to 70°) was accurately marked by means of a ſtop-watch, and the reſults of the experiments on ſeveral fluids, are exhibited in the following table.

ſliding the point up or down in the groove in the blade of the ſquare, it will be brought to cover the object; he then marks the point *m*, and finds another in the ſame manner; when points are thus found, it will be eaſy to connect them by lines, and thus complete the outline; the point at *m* ſhould be fixed to a ſpring, the tendency of which is to throw it off the paper, a braſs button ſhould be fixed on the end of the point, by preſſing which it will prick the paper; an inſtrument of this kind was contrived by Mr. James Peacock, who publiſhed an account of it in the Philoſ. Tranſactions. The frame of this machine will alſo explain the manner in which the two foregoing inſtruments may be ſupported.

Figs. 2, and 3, are repreſentations of a delineator deſcribed in the Philoſophical Journal, vol. i. by Mr. R. L. Edgeworth, who aſcribes the invention to Miſs Maria Edgeworth; the machine is exceedingly ſimple, conſiſting of three mahogany boards; *a b d, fig.* 2, joined together by hinges, which are connected with a common drawing board, *e f g*, to *fig.* 3, by ſcrewing the board *a* to the drawing board, and by putting one end of the paper under the board *a*, it will be fixed down; *k* is the ſight, capable of being elevated or depreſſed as occaſion requires: in uſing the inſtrument the obſerver looks through the ſight, the boards being laid out flat as in *fig.* 2, and directs the point of the index *l m*, to interſect the object he wiſhes to delineate; he then doubles up the machine as in *fig.* 3, bringing the index upon the paper, but taking care not to move the index with reſpect to itſelf; he then marks the place where the point of the index lies, and makes another obſervation; having thus obtained ſeveral points, he proceeds to draw the lines and finiſh the outline.

The camera obſcura is frequently uſed as a delineator, for a deſcription of which ſee that article; though the ſize which this inſtrument muſt have to anſwer the purpoſe effectually, is an objection to it, which, however, applies to all the machines we have hitherto deſcribed. The optigraph, invented by the celebrated Ramſden, ſhewn in *figs.* 4 and 5, poſſeſſes ſeveral advantages over the other machines, as it is portable, and the obſerver views whatever he is going to draw through a teleſcope, enabling him to delineate more minute objects than can be correctly done by any other method. Since the deceaſe of this great artiſt, Mr. Thomas Jones, of Mount-ſtreet, Berkeley-ſquare, London, a pupil of his, has improved the conſtruction of the inſtrument, particularly in adapting the means whereby the drawing made by the machine may be enlarged or diminiſhed, without removing the inſtrument to a greater diſtance from the object; a drawing and deſcription of this inſtrument are to be found in the Philoſophical Magazine, vol. xxviiii. p. 67. *Fig.* 4, is a perſpective view of this inſtrument, A repreſents the drawing board, on the outſide frame of which is fixed the pillar of the inſtrument B, C is a tube (ſliding in the pillar), on the top of which is fixed, by means of a ſcrew *c*, the frame D; at the end of this frame is a plain mirror E, beneath which is ſuſpended by a univerſal joint, the teleſcope F, of which G is the eye tube. H are ſliding tubes, capable of being ſhortened or lengthened in the ſame proportion as the inſide ſpeculum *c*, *fig.* 5, which is fixed to any place by the clamp ſcrew E. The pencil L, of which *h* is the handle, ſlides perfectly eaſy, without ſhake, in the tubes H: the pencil is ſo contrived as to have all the freedom of a pen when held in the hand for uſe.

Fig. 5, repreſents a ſection of the teleſcope, being the principal part of the invention. The rays from an object coming to the plane mirror E, are reflected into the teleſcope, paſſing through the object glaſs *b*, and entering the ſpeculum *a* are reflected through the eye-glaſs *d*, to the eye at *e*; *f* is a piece of parallel glaſs, with a ſmall dot on its centre, exactly in the focus of the eye-glaſs *d*.

Mode of uſing the Optigraph.

Fix the drawing board to the table (by a clamp which is packed in the box), ſo that the ſurface of the mirror E is nearly parallel to the object; then take hold of the handle *h*, and hold the pencil on that part of the paper where you would wiſh the centre of your drawing, or any part thereof, to be. Then place your eye at the eye tube G, and with your left hand alter the inclination of the mirror E, until the ſmall dot deſcribed at *f*, in *fig.* 5, is on ſome particular part of the object that you wiſh to begin with, adjuſting the teleſcope to diſtinct viſion by the milled head P. Then by moving your hand (having the pencil), you paſs the dot ſeen in the field of the teleſcope over the object, the pencil marking it at the ſame time on the paper.

To make your drawing larger, pull out the tube of the pillar C, *fig.* 4, and fix it with the ſcrew *e*; then pull out the ſliding tubes H, till the pencil is within half an inch of the paper (in the middle of the board) and proceed as before. This inſtrument will pack in a box 14 inches long, 3 deep, and 6 inches wide.

The next delineator we ſhall deſcribe is the camera lucida, invented by Mr. W. H. Wollaſton, and for which he took out a patent in 1806; for portability this exceeds all other inſtruments for the ſame purpoſe. It is repreſented in *fig.* 6, which only explains the ſtand or ſupport for the inſtrument; its principle is explained by *fig.* 7; *a b d e*, is a ſection of a glaſs priſm.

The priſm when in uſe is fixed with the ſide *a b* towards the objects to be delineated, and the eye at the angle *e*; the rays from the objects enter at the ſide *a b*, and falling upon *b* are reflected by it to *d e*, and from thence to the eye at *e*, entering it in a direction perpendicular to what they came to the priſm; in this manner a picture of whatever is before the ſide *a b* is repreſented upon the ſurface *e d*; now to tranſfer this picture to paper, the eye is ſo placed at *e*, that one half of the pupil is employed in viewing the reflected objects, while the other half ſees (by direct viſion clear of the ſide *e d* of the priſm) the paper placed on a table beneath the priſm at *f g*; now a pencil or pen may be traced over this paper, and will appear to the eye as though it was traced over the reflected image. This priſm is mounted in a braſs caſe, leaving open ſuch places as are neceſſary as ſeen in *fig.* 6; a pin *h* is fixed to the caſe of the priſm, and paſſes through a piece of braſs jointed to a tube, *i*. This tube ſlides up and down within another, *k*, which is fixed by a joint to a clamp, *l*, ſcrewed to the table whereon the paper is laid. By ſliding out the tube, *i*, the priſm may be ſet at any height from the table and the ſeveral joints; it may be put in any poſition, ſo as to throw the image upon the proper part of the paper. As the principle of the inſtrument depends upon ſeeing the reflected images of the objects, and the direct viſion of the pencil at the ſame time, the leaſt motion of the eye, at *e*, *fig.* 7, would cauſe it to ſee either the reflected image in the ſurface *d e* alone, or ſee only the pencil and paper at *f g*; to prevent this, a piece of braſs plate, *n*, *fig.* 6, is fixed on by a ſcrew, round which it turns as a centre; it has a ſmall hole through it which can be adjuſted by moving the braſs, to ſee the reflected image and the pencil both at once, ſo that a drawing may be made; but if the pencil ſhould not appear diſtinct enough, the braſs muſt be moved outwards from the priſm; this will enlarge the aperture for direct viſion, and diminiſh that of reflection; on the contrary, if the reflected image ſhould not appear diſtinct enough, the braſs ſight ſhould be moved towards the priſm.

Thoſe perſons whoſe ſight is not quite perfect, will not

ſee both a diſtant and a near object (when brought into one field) with the ſame diſtinctneſs; to remedy this, two lenſes, *r s*, *fig.* 3, are fixed by joints beneath the priſm, the lens *r*, is convex, and muſt be interpoſed between the eye and the pencil, as in the figure, for thoſe perſons who can ſee diſtant objects more diſtinctly than near ones; on the contrary, near ſighted people who cannot ſee diſtant objects diſtinctly, muſt have a concave lens, *s*, turned up before the ſide, *a b*, of the priſm, and, *r*, turned down out of the way.

The priſm being brought ſo near the eye, may be very ſmall; *fig.* 7, is the ſection of it at the full ſize, and the whole inſtrument packs in a box 2 inches wide, 8 long, and half an inch thick, outſide meaſure.

DELINQUENT, a perſon who has committed ſome fault, or offence.

It is the buſineſs of a magiſtrate to be ſevere in puniſhing delinquents.

DELIQUESCENCE, in *Chemiſtry*, is the ſpontaneous liquefaction of any ſaline ſubſtance, by means of the moiſture which it attracts from the air.

DELIQUIATED Potash, is applied generally to the ſub-carbonate of potaſh or ſalt of tartar, when run into a liquid by expoſure to a damp air.

DELIRIUM, in *Medicine*, an alienation of mind connected with fever.

This is the ſenſe in which delirium is commonly underſtood; but by ſome writers, as Hoffman, Sauvages, &c. delirium is the term employed to denote the whole claſs of mental derangements, including the different forms of mania, melancholy, febrile delirium, and ſo forth.

Etymologiſts have derived the term delirium from *de* and *lira*, *i. e.* departing from the right way; *lira* ſignifying a ſtraight furrow carried through a field. Others have preferred a derivation from ληρος, *leræ*, or *liræ*, trifles, or abſurdities. Van Swieten, ad Aph. 700.

Boerhaave defines delirium, "the production of ideas not correſponding with external cauſes, but with an internal diſpoſition of the brain, attended with an erroneous judgment, the reſult of theſe ideas." Aph. 700. Dr. Darwin expreſſes the ſame notion in other terms. "The ideas in delirium conſiſt of thoſe excited by the ſenſation of pleaſure or pain, which precedes them, and the trains of other ideas aſſociated with theſe; and not of thoſe excited by external irritations, or by voluntary exertion." Zoonomia, vol. ii. claſs ii. ord. i. gen. 7. Both theſe definitions point out the diſtinguiſhing character of febrile delirium; namely, that it originates from a certain phyſical condition of the brain: but they are perhaps both, in ſome degree, incorrect, in excluding external impreſſions from among the cauſes of the delirious ideas. It is true, indeed, that the internal ſenſations, and eſpecially thoſe ariſing from the peculiar condition of the circulation in the brain, or of the brain itſelf, are the primary cauſes of delirium; and, accordingly, delirium firſt occurs between ſleeping and waking, eſpecially in the dark; under which circumſtances external impreſſions on the ſenſes are in a conſiderable degree excluded. In this early period, or incipient degree of delirium, when the full opportunity is afforded by the patient awaking completely, and by the return of light, for the operation of external impreſſions, ſince the power of judgment ſtill remains, the morbid aſſociations are corrected, and delirium ceaſes; until the ſenſes are again deprived of their acuteneſs and activity by an imperfect ſleep. But when the morbid condition of the brain is much increaſed, by the increaſe of the febrile diſeaſe, the faculty of judgment is diminiſhed, and the powers of aſſociation and imagination are morbidly increaſed, inſomuch that the external impreſſions on the ſenſes, when they are attended to by the mind, become alſo the cauſes of a train of delirious ideas. Hence the room, in which the patient lies, is not known to him, but is conceived to be a church or a priſon, &c. according to the aſſociations, which particular impreſſions at different times excite; the perſons about him are not known, or viewed partly in their true character, and partly in a fictitious one, as morbid aſſociations are connected with correct impreſſions of their perſons, in an incongruous manner.

Delirium, then, may be conſidered as a ſort of waking dream, in which the faculties of aſſociation and imagination are morbidly excited, in conſequence of a peculiar condition of the brain and nervous ſyſtem, connected with fever.

The nature of delirium may be illuſtrated, therefore, by comparing it with our common dreams; and its various degrees may be traced, from the unpleaſant or frightful dreams occaſioned by a loaded ſtomach, or a ſlight ephemeral feveriſhneſs, up to the moſt violent frenzy, accompanying inflammation of the brain. In our ordinary dreams, when the acceſs of external impreſſions is prevented, the ſenſes being, as it were, ſhut up, and the powers of judgment and volition ſuſpended, the internal ſenſations, with their aſſociations, alone excite the train of ideas. This train runs on, upon the principle of aſſociation alone, from ſcene to ſcene, and from ſubject to ſubject, connecting thus the moſt incongruous aſſemblage of ideas; which, if uttered aloud, would be as apparently unconnected as thoſe of the moſt delirious perſon; but which, under this ſuſpenſion of external ſenſe and volition, excite no ſurpriſe to the dreamer, by their extreme incongruity, becauſe no compariſon is made, no act of judgment is exerted. As the faculty of aſſociation is the leading principle in carrying on theſe trains of our ſleeping ideas, their continuance is endleſs; and in like manner there is a perpetual flow of ideas in delirium, continuing with more rapidity under the increaſed excitement of the brain and nervous ſyſtem. The facility, with which various trains of ideas are aſſociated, in dreams, with particular corporeal ſenſations, may be illuſtrated by the experience of almoſt every individual. Mr. Stewart, in his "Philoſophy of Natural Hiſtory," relates, that he was diſtreſſed by a dream, in which he ſuppoſed himſelf hung up by the throat, upon hooks, in the infernal regions, and ſurrounded by all the ſuppoſed tortures, aſſociated with that idea; and, on waking, he found himſelf ſuffering under the irritation of a ſore throat, the pain of which had excited this ſingular train of ideas. In the ſame way an oppreſſion about the præcordia, ariſing from a loaded ſtomach, or an uneaſy poſture, during ſleep, excites the ideas of thoſe horrible figures, ſitting or lying on the breaſt of the dreamer, which perſons attacked with *incubus*, or night-mare, are ſaid to experience. And again, when the ſleep is leſs complete, and the ſenſes, as of hearing, touch, and ſmell, are more open to impreſſion, noiſes, and other irritations, imperfectly and indiſtinctly perceived, mingle, nevertheleſs, with our dreams, and become the cauſes of different trains of aſſociation. See Dreams.

When a ſlight febrile action is induced, as from a common cold; from an over doſe of ſome ſtimulant, as wine, or ſpirits; or from ſome narcotic medicine, ſuch as opium; a ſtate of the brain and nervous ſyſtem is produced, which greatly increaſes this diſpoſition to aſſociate various trains of ideas, with the ſenſations and irritations of the different parts of the body; and the dreams are inceſſant and various. If the ſenſations are pleaſurable, the dreams are agreeable; if, on the contrary, as is generally the caſe, the ſenſations approach to pain, the aſſociated ideas are of a diſagreeable nature, and imaginary objects of terror and danger are brought before the mind.

If

If the febrile condition is more completely eſtabliſhed, the ſenſations of the body become more generally painful, the whole nervous ſyſtem is in a diſturbed ſtate, and the brain itſelf is particularly excited; ſo that the mind is engroſſed, as it were, by the internal ſenſations, which, in this ſenſitive condition of the brain, make the greater impreſſion, and thoſe of external objects excite little of its attention; or, when they are perceived, combine with the others to produce the delirious dreams of the patient.

As the excitement ſtill farther increaſes, he utters his dreams aloud, and his words, of courſe, are characterized by all the incongruity of the ideas, which they repreſent. When the excitement proceeds to a ſtill higher pitch, and eſpecially when it amounts to inflammation of the brain, the train of delirious ideas becomes ſtill more rapid and incongruous, it calls the paſſions forth, and is combined with great reſtleſſneſs of the muſcles, and impatience of reſtraint; which conſtitute frenzy, and with certain other ſymptoms mark the exiſtence of phrenitis.

The delirium, when arrived at this degree, (the *delirium ferox* of writers) is evidently the conſequence of an increaſed action of the arteries of the brain, and therefore of an increaſed quantity and impetus of the blood in that organ. The appearances of external inflammation teach us, that the ſenſorial functions of every part are increaſed by an increaſed quantity and impetus of the blood, which circulates through it. Hence the pain, the acute ſenſibility, of a common boil or whitlow. And that ſuch is the condition of the brain, where there is violent delirium, we have evidence both from the accompanying ſymptoms, and from examinations after death. The ſymptoms accompanying violent delirium, are generally redneſs of the countenance, pain in the head, ſtrong arterial pulſations, a ferrety redneſs of the eyes, which are acutely ſenſible to light, &c.; and on diſſection, a redneſs has been obſerved in different parts of the brain, and in its membranes, on which coagulable lymph has been poured out, adheſions formed, pus collected, and ſo forth. Various degrees of this delirium, then, are connected with more or leſs of a morbid determination of blood to the brain.

A delirium, however, occurs under other circumſtances of the brain, which is different in its character, and is called a low delirium, *delirium mite*. This is generally conſidered by writers as the reſult of a circulation through the brain too languid to ſupport its functions. The ideas flow leſs rapidly than in the acute delirium; and the patient lies on his back, muttering to himſelf, and altogether inattentive to what is paſſing around him; in ſhort in a ſtate approaching rather to ſtupor, than to active thought. From this he can at firſt be rouſed for a few moments, and be made ſenſible to external impreſſions, even to queſtions put to him; but he ſpeedily relapſes into inattention; and, as the diſordered ſtate or atony of the brain is increaſed, this degenerates into complete ſtupor; he becomes inſenſible to all the calls of nature, ſo that he feels not even the thirſt, which parches his throat, and the urine and fæces are evacuated unconſciouſly. If the diſeaſe ſtill proceeds, *ſubſultus tendinum*, tremors, convulſions, and death enſue.

With this ſpecies of delirium, the concomitant ſymptoms mark a deficiency of nervous energy, and of the impetus of the circulation. It occurs in the laſt ſtages of low fevers, ſometimes in the cold ſtage at the commencement. (Cullen.) The pulſe is ſmall and feeble, the countenance pale and ſunk, the general ſtrength much impaired, and giddineſs is ſometimes obſerved, on aſſuming the erect poſture. The pain of the head is dull and heavy, not acute, as in the former ſpecies of delirium. And, it may be added, that the former ſpecies is ſometimes converted into this, when the ſtrength of the patient is greatly ſunk. It muſt be obſerved, however, that the brain and nervous ſyſtem are affected, in fevers, in a way not altogether to be accounted for, from the ſtate of the circulation; as there is often, from the commencement, a remarkable proſtration of the animal powers.

Delirium of either ſpecies, when exiſting in any conſiderable degree, affords an unfavourable prognoſis, as to the event of the fever: but the exiſtence of the low delirium is conſidered as leſs unfavourable than that of the acute. For although both imply a morbid derangement of the functions of one of the moſt important organs of life; yet the atonic ſtate, if we may uſe the term, is leſs liable to occaſion irremediable injury to the brain, and is more eaſily removed, than the ſtate of high excitement, which accompanies the violent delirium.

The occurrence of delirium may be often anticipated from an obſervation of the other ſymptoms. When the head-ache is very acute, when there is great reſtleſſneſs and indiſpoſition to ſleep, when the eyes are acutely ſenſible to light, or other ſymptoms of a particular determination of blood to the head are preſent, delirium may be expected to follow. Huxham has remarked, on the ſame principle, that a ſtrong pulſation of the carotid arteries, in the advanced ſtage of fever, although the pulſe at the wriſt may be ſmall, nay even ſlow, "is a certain ſign of an impending delirium, and generally proceeds from ſome conſiderable obſtruction in the brain." (Eſſay on Fevers, p. 94.) Many ſymptoms of impending delirium are enumerated by Hippocrates, in his book on prognoſtics, ſome of which, however, ſeem to be fanciful, and others to apply rather to inſanity than to febrile delirium.

As delirium is of two ſpecies, and connected with two oppoſite conditions of the ſenſorium, it is obvious that the remedies by which it muſt be combated, muſt be varied according to its nature, and the concomitant ſymptoms. When it is of the acute ſpecies, and evidently connected with an increaſed action in the brain, the indication will be to diminiſh the arterial action, and thus to leſſen the quantity and impetus of the blood, ſent to that organ. This indication may be accompliſhed by the local abſtraction of blood from the head; as by the application of leeches, or the cupping-glaſſes, to the temples or neck; by ſhaving the head, and reducing its temperature, by waſhing with cold water, or water and vinegar; or by applying a bliſtering plaſter over the ſcalp, or on the neck. And where there is, at the ſame time, a great general increaſe of the arterial action, theſe operations may be aided by whatever tends to diminiſh the general fever. Hence the general affuſion of cold water, the uſe of the ſhower-bath, or waſhing the whole ſurface by means of a ſponge, is often extremely efficacious in removing delirium. At the ſame time, the general antiphlogiſtic regimen, the free uſe of diluent drinks, laxative medicines, and cool air, ſhould be enjoined; and every ſource of irritation whatever, ſuch as ſtrong light, noiſes, converſation of viſitors, motion or exertion of the body, &c., ſhould be ſtudiouſly avoided. In this ſtate of excitement of the brain and nervous ſyſtem, circumſtances which ordinarily have little or no influence, irritate to a pernicious degree. Hence if the bowels are loaded, the removal of the irritating fæces by a laxative will ſometimes remove the delirium; and the abſtraction of other irritations diſtant from the brain, will often have a ſimilar beneficial effect.

In the low delirium, occurring in fevers with great debility, where the heat of the ſkin is not increaſed, and there are no marks of active determination to the head, a different plan of treatment is required. The patient muſt be ſupported by the frequent adminiſtration of cordial medicines, of which wine is perhaps the beſt. Where there is much watching

and

and reſtleſsneſs, an opiate will often contribute greatly to correct the delirium, by inducing ſleep, and ſoothing the nervous ſyſtem, which it renders leſs ſenſible to the little irritations of the febrile ſtate. Small quantities of liquid nutriment ſhould be frequently adminiſtered, in aid of the ſupport afforded by the cordials. If the ſtrength ſinks rapidly, the more powerful ſtimulants of alcohol, æther, and the volatile medicines will be requiſite. See Gregory Conſpectus Medicinæ Theoret. Van Swieten. ad Aph. 700 et ſeq. Cullen, Firſt Lines, 45.

DELITZSCH, anciently Deliz, *Delitium*, in *Geography*, a ſmall town of Saxony, in the circle of Leipzig, on the river Löber; 12 miles N. of Leipzig, on the road to Deſſau; was built in the tenth century by the Vandals, and has a royal palace and garden. It contains 3000 inhabitants, and is remarkable for its manufacture of worſted ſtockings, and a printing preſs, which has been eſtabliſhed here above 120 years. The town is encircled by double rows of lime and willow trees, which afford very pleaſant walks.

DELIVER, *To*, to give freedom, or to releaſe any one from confinement, captivity, or bondage, to relieve the mind oppreſſed with care, anxiety, or trouble, or to ſurrender or give up any place or property. It is alſo uſed for utterance, as to ſpeak, or deliver a diſcourſe. In midwifery it means to bring a child into the world.

DELIVERANCE, in *Law*, a term uſed when a criminal is brought to trial, and the clerk in court aſks him whether he is guilty, or not guilty, to which he replies not guilty, and puts himſelf on God and his country; and the clerk wiſhes him "a good deliverance."

Deliverance, *a writ of ſecond*, a judicial writ, iſſuing out of the original record, allowed by the ſtatute of Weſtm. 2. c. 2. to the plaintiff, who is reſtrained by it, when non-ſuited, from ſuing out any freſh replevin, ſo called becauſe he has the ſame diſtreſs again delivered to him, on giving the like ſecurity as before. If the plaintiff be a ſecond time non-ſuit, or if the defendant has judgment upon verdict or demurrer in the firſt replevin, he ſhall have a writ of "return irreplevisable;" after which no writ of ſecond deliverance ſhall be allowed. (2 Inſt. 340.) But in caſe of a diſtreſs for rent arrere, the writ of ſecond deliverance is in effect taken away by ſtatute 17 Car. II. c. 7., which directs another proceſs. 1 Vent. 64.

Deliverance, *Cape*, in *Geography*, a cape on the coaſt of New Guinea, in the Eaſt Indian ocean. S. lat. 11° 30'. E. long. 157° 50'.

DELIVERY, in *Midwifery*, the act of parturition, or of bringing into the world a full grown fœtus. See Labour.

Delivery, in *Law*, is an eſſential requiſite of a valid deed, which is done by the party himſelf, or his attorney, lawfully authoriſed, and expreſſed in the atteſtation. This delivery is either abſolute, *i. e.* to the party or granter himſelf; or conditional to a third perſon to hold, till ſome conditions be performed on the part of the granter. See Deed.

Delivery, in *Oratory*. See Pronunciation.

DELIUM, or Delion, in *Ancient Geography*, a town of Greece, in Bœotia, ſituated on the ſea-coaſt, on the frontiers of the territory of Tanagra and Attica, N. of the mouth of the Aſopus. It had a temple dedicated to Apollo. In the time of Pauſanias it had two ſtatues, one of Diana, and another of Latona.

DELIUS, Christopher Traugott, in *Biography*, was born at Wallhauſen in Thuringia. Being of a noble and wealthy family, he was brought up for the army, in which he ſerved a long time. He afterwards applied himſelf with much diligence to the ſciences, embraced the Catholic religion, and obtained a place in the eſtabliſhment of the Hungarian mines, where he roſe to the poſt of profeſſor in the academy of mines at Chemnitz. Having ſuſtained this character with much reputation he was at length invited to Vienna, where he was employed in the department of the mines and the mint. He died at Florence in January 1779. in the fifty-firſt year of his age As an author he bears a very reſpectable character. His works are, "A Diſſertation on the Origin of Mountains, and of the different kinds of Veins found in them; alſo of the mineralization of Metals, and particularly of Gold." "An Introduction to the art of Mining, both in theory and practice, together with a treatiſe on the principles of the economy of Mines." The latter was tranſlated into French, by the order and at the expence of the king of France.

DELKENHEIM, or Telkenheim, in *Geography*, a ſmall town of the grand duchy of Heſſe Darmſtadt, in Germany, ſituated in the diſtrict of Epſtein.

DELKIRAS, a town of Aſiatic Turkey, in the province of Natolia; 40 miles W. of Tocat.

DELLAMCOTTA, a fortreſs of Aſia, in the country of Bootan, which commands the principal paſs over the ſouthernmoſt ridge of the Bootan mountains, that riſe nearly 1½ mile perpendicular above the plains of Bengal, in a horizontal diſtance of only 15 miles. This fort was taken by ſtorm in 1773, by a detachment under the command of capt. John Jones; the fame of which exploit made the Thebetians ſue for peace. It is 50 miles diſtant from Taſſaſudon, and 175 N. from Moorſhedabad.

DELLE, a ſmall town of France, in the department of the Upper Rhine, chief place of a canton, in the diſtrict of Befort, with a population of 810 individuals, 6 miles N. W. of Porentruy. The canton has an extent of 192½ kiliometres, 27 communes, and 8952 inhabitants.

Delle, *Cape*, a cape of Africa, in the Mediterranean, on the coaſt of Algiers. N. lat. 37° 15'. E. long. 4° 13'.

DELLYS, or Teddeles, a ſea-port of Africa, in the country of Algiers; 15 leagues E. of Algiers.

DELME, a ſmall town of France, in the department of the Meurthe, chief place of a canton, in the diſtrict of Chateau-Salins. It has only 374 inhabitants. Its canton has a population of 5215 individuals, diſperſed in 22 communes, upon a territorial extent of 127 kiliometres and a half. —Alſo, a ſmall river of Germany, in the county of Delmenhorſt.

DELMENHORST, a town of Germany, in the duchy of Holſtein Oldenburg, chief place of the county of the ſame name, ſituated on the river Delme not far from the Weſer, 9 miles S. W. of Bremen, and 21 miles S.E. of Oldenburg. N. lat. 53° 10'. E. long. 8° 11'. This county and Oldenburg belonged to Denmark till the year 1773, when both were exchanged againſt the duchy of Holſtein.

DELMONT, Deodato, in *Biography*, an hiſtorical painter, was born at St. Tron in 1581, of a good family, who gave him a liberal education, and placed him with Rubens to learn deſign and colouring. Being the intimate friend, as well as diſciple of this illuſtrious painter, he accompanied him to Italy, and at Rome ſo diligently and ſo ſucceſsfully proſecuted his ſtudies in painting, ſtatuary, and architecture, that he obtained the reputation of being an excellent painter and architect. At the court of Newburgh, where he was employed for a long time, he was ennobled in token of his merit. Several excellent paintings of this maſter are preſerved in the churches and convents of Italy; and at Antwerp there are three capital performances; *viz.* the Transfiguration in the church of Notredame, Chriſt carrying his croſs in the Jeſuits' church, and the Adoration of the Magi, in a cloiſter. In all his ſubjects the compoſition is elevated,

elevated, the deſign correct, and the colouring and pencilling excellent. The praiſe of Rubens is of itſelf ſufficient to immortalize this artiſt, who died in 1634. Pilkington.

DELOS, in *Ancient Geography*, an iſland of the Ægean ſea, or Grecian Archipelago, ſituated nearly in the centre of the *Cyclades* (which ſee) and placed by Pliny, (l. iv. c. 12.) at the diſtance of 15 miles from Myconus, 18 from Naxos, and 50 from Icaria. But theſe diſtances are undoubtedly erroneous, as Myconus is diſtant from Delos only 3 miles, and Naxos 40. This iſland was known to the ancients by the names of Cynethos or Cynthos, Aſteria, Pelaſgia, Chlamydias, Lagia, Pyrpilis, Scythias, Mydia, and Ortygia, It was named Ortygia and Lagia, from two Greek words, *ortyx* and *lagos*, the former ſignifying a quail, and the latter a hare, the iſland formerly abounding with both theſe animals. The name Delos is derived by the Etymologiſts from a Greek verb ſignifying to *appear*, but they differ as to the reaſon of its being appropriated to this iſland. Pliny, after Ariſtotle, pretends that the name was given to this iſland, becauſe it roſe unexpectedly out of the ſea, and appeared floating on the water. Some ſay that it was called Delos or manifeſtation, becauſe it was the birth-place of Apollo, the ſymbol of the ſun, and becauſe the beams of this luminary enlighten the whole earth. The poets pretend that this iſland was named Delos, becauſe Latona, being delivered of Apollo and Diana, ſhowed herſelf firſt here, not having dared to appear before, for fear of Juno. The fable reports that it floated at the mercy of the winds; but Herodotus examined it with attention, and denies the fact. Some fabulous writers ſay that it was fixed by the voice of Neptune, and others pretend that it was raiſed by a blow of his trident from the bottom of the ſea, in order to accommodate Latona, the miſtreſs of Jupiter, with a place for the birth of her children, when ſhe was perſecuted by Juno. Strabo repreſents it as an iſland of ſmall extent; and, according to Pliny, it was not more than 5 miles in compaſs; but Tournefort aſſigns it a circuit of 7 or 8 miles. The native deities, Apollo and Diana, had three very magnificent temples erected for them in this iſland. That of Apollo was, according to Strabo, (lib. x.) begun by Eryſiapthus, the ſon of Cecrops, who is ſaid to have poſſeſſed this iſland 1558 years B.C.; but it was afterwards much enlarged and embelliſhed at the general charge of all the Grecian ſtates. But Plutarch ſays, that it was one of the moſt ſtately buildings in the univerſe, and deſcribes its altar, as deſerving a place among the ſeven wonders of the world. The inſcription in this temple, as Ariſtotle informs us, (Ethic. l. i. c. 9.) was as follows: "Of all things the moſt beautiful is juſtice; the moſt uſeful is health; and the moſt agreeable is the poſſeſſion of the beloved object." The trunk of the famous ſtatue of Apollo, mentioned by Strabo and Pliny, has been for ages an object of admiration to travellers; its ſize was gigantic, though cut out of a ſingle block of marble, the ſhoulders being ſix feet broad, and the thighs nine feet round. Round the temple of Apollo were magnificent porticoes, built at the charge of various princes, as appears from the ſtill legible inſcriptions. To this temple the neighbouring iſlands ſent yearly a company of virgins to celebrate with dancing the feſtival of Apollo, and his ſiſter Diana, and to make offerings in the name of their reſpective cities.

Delos was held in ſuch reverence by moſt nations, that even the Perſians, after having laid waſte the other iſlands, and every where deſtroyed the temples of the gods, ſpared Delos; and Datis, the Perſian admiral, forbore to anchor in that harbour. This iſland was celebrated both by the poets and hiſtorians of antiquity: the poets, it is ſaid, by Callimachus, preſented in this place the firſt tribute of their ſervices; for the favour of Apollo could not be obtained any where elſe. Pieces of muſic and poetry were diſtributed at the games celebrated here in honour of Apollo. See DELIAN *Games*. The Athenians made an annual proceſſion to the iſland of Delos. The author of this ceremony was Theſeus, who being ſent with other Athenian youths into Crete (ſee CRETE,) to be devoured by the Minotaur, made a vow to Apollo, that if he granted them a ſafe return, they ſhould make a ſolemn voyage to his temple in Delos every year. We learn from Strabo and Callimachus, that this iſland was watered by the river Inapus. Pliny calls it a ſpring, and adds, that its waters ſwelled and abated at the ſame time with thoſe of the Nile, as if there had been a communication between the Nile and the Inapus. The iſland has now no river, but one of the nobleſt ſprings in the whole Archipelago, being twelve paces in diameter, and encloſed partly by rocks, and partly by a wall. This iſland was anciently governed by kings; for Virgil mentions a king named Anius, who reigned here in the time of the Trojan war. He was both king and high-prieſt of Apollo, and entertained Æneas with great kindneſs. This prince was deſcended from Cadmus, and had by his wife Dorippe three daughters, who are feigned by the poets to have derived from Bacchus the power of changing whatever they touched into wine, wheat-ſeed, or oil; alluding to the great quantity of wine, wheat, and oil, which accrued to their father from the offerings made to Apollo. Joſhua, it is ſaid, in the 15th century before Chriſt, having driven the Phœnicians from the land of Canaan, they paſſed into the iſlands of the Ægean ſea, and eſtabliſhed themſelves in theſe iſlands, and particularly in that of Delos. Thucydides ſays, that theſe people, blended with the Carians, practiſed piracy. The Athenians, who afterwards made themſelves maſters of Delos, were commanded by an oracle, as Herodotus informs us, (lib. i. c. 64). to purify the iſland, which he did by cauſing all the dead bodies to be taken up, and removed from all places within the proſpect of the temple. In the 6th year of the Peloponneſian war, the Athenians, by the advice of an oracle, purified it anew, by carrying all the dead bodies to the iſland of Rhenæa, where they were interred. Having then cleared it from ſepulchres, in order to preſerve it from pollution, they publiſhed an edict, enacting that for the future no perſon ſhould be ſuffered to die, nor any woman to be brought to bed in the iſland; but when death or parturition approached, they ſhould be carried over into Rhenæa. In memory of this purification, the Athenians inſtituted a ſolemn feaſt, which was celebrated every fifth year, (ſee DELIA;) people aſſembling on that occaſion to Delos from the neighbouring iſlands, and all parts of Greece. A few years after, the Athenians, to complete the purification of the iſland, expelled all the ancient inhabitants, whom they pretended to be polluted, on account of a crime committed by them in former times, but not mentioned by our hiſtorians. The Athenians were driven out by Mithridates the Great, who plundered the rich temple of Apollo, and obliged the Delians to take part with him. Mithridates, in his turn, loſt it to the Romans, who granted many privileges to the inhabitants, and exempted them from all kinds of tribute and taxes. The lands are now ſo covered with ruins and rubbiſh, as to admit of no ſort of culture; yet the inhabitants of Myconi hold it, by paying ten crowns land-tax to the grand Signior.

The oracle of Apollo, in Delos, was one of the moſt famous oracles in the world, not only for its antiquity, but for the richneſs of the ſacred preſents dedicated to the god, and the numbers of perſons that reſorted hither from all parts for advice; in which reſpect it ſurpaſſed not only all the oracles of other gods, but thoſe of Apollo himſelf, that of Delphi alone excepted. Some writers ſay, that the iſland had the

name

name of Delos, from the clear and ſimple terms in which the anſwers were here given by the oracle, contrary to the ambiguity obſerved in other places; but it was conſulted only while Apollo made Delos his ſummer reſidence, for his winter abode was at Patara, a city of Lycia. The preſents offered by the votaries to Apollo, were laid in the altar already mentioned, which altar, as ſome ſay, was erected by Apollo himſelf, when he was only four years old, and formed of the horns of goats, killed by Diana, on mount Cynthus. It was preſerved pure from blood and every kind of pollution, as offenſive to Apollo. The whole iſland was an aſylum, which extended to all living creatures, dogs excepted, which were not ſuffered to be brought on ſhore, and therefore it abounded with hares.

Delos, the capital of the iſland of the ſame name. It occupied, as its magnificent ruins evince, that ſpacious plain which reaches from one coaſt to the other, and extends eaſtward as far as the Iſthmus. It was the richeſt city in the Archipelago, eſpecially after the deſtruction of Corinth; merchants being allured hither from all parts, by the immunities they enjoyed, and by its convenient ſituation between Europe and Aſia. Strabo calls it one of the moſt frequented emporiums of the world; and Pliny tells us, that all the commodities of Europe and Aſia were ſold, purchaſed, or exchanged there. It contained many noble and ſtately buildings; *viz.* the temples of Apollo, Diana, and Latona, and alſo thoſe of Neptune and Hercules; the porticoes of Philip of Macedon, and of Dionyſius Eutyches: a gymnaſium, an oval baſon, about 48 toiſes in diameter, made at an immenſe expence, for teaching the inhabitants to ſwim, and for the exhibition of ſea-fights; and a magnificent theatre of white marble, 250 feet in diameter; and a citadel.

Delos, or Deli, in *Geography*, an iſland of the Grecian Archipelago, formerly famous, as we have ſeen in the preceding article, is now little more than a deſert rock, covered with ruins and uninhabited. Under the plural name Deli, are comprehended two iſlands, *viz.* Little Delos, 7 miles in compaſs, and Great Delos, which is included within a circuit of 18 miles, known to the ancients by the name of Rhenæa, which at ſome diſtance ſeems to be joined to Delos. It is now the refuge of pirates. Every where, ſays Olivier, ſchiſtous or granitical, it exhibits no trace of a volcano, and nothing that can explain, by the laws of phyſics, the wonders which the Greeks have tranſmitted to us reſpecting it; near it is mount *Cynthus*; which ſee.

DELPHI, or Delphos, now called *Caſtri*, the capital of Phocis, in Greece, ſituated in a valley towards the S.W. of the foot of one of the brows of mount Parnaſſus, ſo famous in antiquity and ſacred to the Muſes and Apollo; and anciently much celebrated for its temple and oracle of Apollo. It was alſo called *Pytho*, particularly by the poets; deriving this name, as ſome have ſaid, from the ſerpent Python, which Apollo killed in this place. Pauſanias, however, ſays that this name Pytho was given to the city of Delphos, by Pythis, ſon of Delphus, and grandſon of Lycorus. The Greek hiſtorians give to this city the name of Delphos, which ſome ſuppoſe to have been ſo called from αδελφοι, brethren, becauſe Apollo and his brother Bacchus were both worſhipped there; and others, with greater probability, derive the name from δελφος, ſingle, or ſolitary, referring to the retired ſituation of the city among the mountains. Delphos was only 7 ſtadia in circuit, and the rocks that encompaſſed it formed its natural fortifications. One of the ſummits of Parnaſſus covered it on the north; another craggy rock, called "Cirphis," defended it on the ſouth. Juſtin queries, which was moſt worthy of admiration, the fortification of the place, or the majeſty of the god, who here delivered his oracles. "Incertum, utrum loci, an majeſtas dei plus hic admirationis habeat." This city was built in the form of a kind of amphitheatre, and was divided into three parts, one riſing, as it were, above the other. Strabo places Delphos in the middle of Greece, and ſome of the ancients conceiving it to be in the middle of the world, called it the navel of the earth; the poets pretending that Jupiter, in order to aſcertain the middle of the earth, let fly two eagles; or according to Pindar, two crows, the one from the eaſt and the other from the weſt, and that they met in this place. It had, however, ſo convenient a harbour, and was ſo well ſituated, being rather in the heart of Greece than of the world, that it became in time the place where the Grecian ſtates aſſembled, and where the court of the Amphictyons ſat. At preſent the town of Caſtri does not conſiſt of above 200 houſes, and thoſe very ill built. It ſtands between Salene and Livadia, about 10 miles diſtant from the latter, on the ſouth ſide of mount Parnaſſus. The temple of Apollo occupied, according to Pauſanias, a large ſpace, and many ſtreets met here. The firſt diſcovery of the oracle, which laid the foundation of the extraordinary veneration in which this place was held, and of the riches accumulated in the temple, is ſaid to have been as follows: it was occaſioned by ſome goats which were feeding on mount Parnaſſus, near a deep and large cavern, with a narrow entrance. Theſe goats having been obſerved by the goat-herd, called Coretas by Plutarch, to friſk, and leap after a ſtrange manner, and to utter unuſual ſounds immediately upon their approach to the mouth of the cavern, he had the curioſity to view it, and found himſelf ſeized with the like fit of madneſs, ſkipping, dancing, and foretelling things to come. At the news of this diſcovery, multitudes flocked thither, many of whom were poſſeſſed with ſuch phrenetic enthuſiaſm, that they threw themſelves headlong into the opening of the cavern; inſomuch, that it was neceſſary to iſſue an edict, forbidding all perſons to approach the cavern. This ſurpriſing place was treated with ſingular veneration, and ſoon covered with a kind of chapel, which Pauſanias tells us was originally made of laurel boughs, and reſembled a large hut. This, if we may credit the Phocian tradition, was ſurrounded by one of wax, and raiſed up by the bees. After this a third was built of ſolid copper, ſaid to have been the workmanſhip of Vulcan. This laſt was deſtroyed, as ſome ſay, by an earthquake, or, according to others, by a fire, which melted the copper; and then a ſumptuous temple, altogether of ſtone, was erected by Trophimus and Agamedes, two excellent architects. This edifice was deſtroyed by fire in the 58th Olympiad, 548 years B. C. The Amphictyons propoſed to be at the charge of building another; but the Alcmeonides, a rich family of Athens, came to Delphos, obtained the honour of executing the building, and made it more magnificent than they had at firſt propoſed. The riches of this temple, amaſſed by the donations of thoſe who frequented it and conſulted the oracle, expoſed it to various depredations. At length the Gauls, under the conduct of Brennus, came hither for the ſame purpoſe, about 278 years B. C.; but they were repulſed with great ſlaughter. Laſt of all, Nero robbed it of 500 of the moſt precious ſtatues.

It has not been aſcertained at what time this oracle was founded. It is certain, however, that Apollo was not the firſt who was conſulted here. Æſchylus, in his tragedy of the Eumenides, ſays, Terra was the firſt who iſſued oracles at Delphi: after her Themis, then Phœbe, another daughter of Terra, and, as it is ſaid, mother of Latona, and grandmother to Apollo. Pauſanias ſays, that before Themis, Terra and Neptune had delivered oracles in this place, and ſome ſay that Saturn had alſo been conſulted here. At length the oracle of Apollo became eſtabliſhed

and permanent; and ſuch was its reputation, and ſuch were the multitudes from all parts that came to conſult it, that the riches which were thus brought into the temple and city became ſo conſiderable as to be compared with thoſe of the Perſian kings. About the time when this oracle was firſt diſcovered, the whole myſtery requiſite for obtaining the prophetic gift was to approach the cavern and inhale the vapour that iſſued from it; and then the god inſpired all perſons indifferently; but at length ſeveral enthuſiaſts, in the exceſs of their fury, having thrown themſelves headlong into the cavern, it was thought expedient to contrive a prevention of this accident, which frequently occurred. Accordingly, they placed over the hole, whence the vapour iſſued, a machine which they called "a tripod," becauſe it had three feet, and commiſſioned a woman to ſeat herſelf in this ſort of chair, where ſhe might imbibe the vapour without danger, becauſe the three feet of the machine ſtood firmly upon the rock. This prieſteſs was named "Pythia," from the ſerpent Python, ſlain by Apollo, or from the Greek πυθεσθαι, ſignifying to inquire, becauſe people came to Delphi to conſult this deity. The females firſt employed were virgins ſelected with great precaution; but the only qualification neceſſary was to be able to ſpeak and repeat what the god dictated. The cuſtom of chooſing young virgins continued for a long time, till one of them, who was extremely beautiful, was diſhonoured by a young Theſſalian. An expreſs law was then enacted, that none ſhould be choſen but women above 50 years old. At firſt there was only one prieſteſs; but afterwards, there were two or three. The oracles were not delivered every day; but ſacrifices were in ſome caſes preſented for a long time, and even for a whole year; and it was once a year in the month βοσιον, which anſwered to the beginning of ſpring, that Apollo inſpired the prieſteſs. Except on this day, ſhe was forbidden, under pain of death, to go into the ſanctuary to conſult Apollo. Alexander, before his expedition into Aſia, came to Delphi on one of thoſe days when the ſanctuary was ſhut, and intreated the prieſteſs to mount the tripod, which ſhe ſteadily refuſed, alleging the law which forbade her. The prince, naturally impetuous, became impatient, and drew the prieſteſs by force from her cell, and whilſt he was conducting her to the ſanctuary, ſhe took occaſion to exclaim, "My ſon, thou art invincible." As ſoon as theſe words were pronounced, Alexander cried out that he was ſatisfied, and would have no other oracle. Great preparations were made for giving myſteriouſneſs to the oracle, and for commanding the reſpect that was paid to it. Among other circumſtances relating to the ſacrifices that were offered, we may obſerve that the prieſteſs herſelf faſted three days, and before ſhe aſcended the tripod, ſhe bathed herſelf in the fountain of Caſtalia. She drank water from that fountain, and chewed laurel-leaves gathered near it. She was then led into the ſanctuary by the prieſts, who placed her upon the tripod. As ſoon as ſhe began to be agitated by the divine exhalation, her hair ſtood on end, her aſpect became wild and ghaſtly, her mouth began to foam, and her whole body was ſuddenly ſeized with violent tremblings. In this condition ſhe attempted to eſcape from the prophets, who detained her by force, while her ſhrieks and howlings made the whole temple to reſound, and filled the by-ſtanders with a ſacred horror. At length, unable to reſiſt the impulſe of the god, ſhe ſurrendered herſelf to him, and at certain intervals uttered from the bottom of her ſtomach, or rather from her belly, according to the expreſſion εγγαστριμυθος, ſome unconnected words, which the prophets ranged in order, and put in form of verſe, giving them a connection which they had not when they were delivered by the prieſteſs. The oracle being pronounced, ſhe was taken off the tripod, and conducted back to her cell, where ſhe continued ſeveral days to recover herſelf from her conflict. Lucan tells us, (Pharſal. lib. v.) that ſpeedy death was frequently the conſequence of her enthuſiaſm. The oracles pronounced by the prieſteſs were generally delivered to the poets who attended on the occaſion, and who put them into wretched verſe, which gave occaſion to the raillery, that Apollo the prince of the muſes was the worſt of poets. Sometimes the prieſteſs herſelf pronounced her oracles in verſe; but in later times they contented themſelves with delivering them in proſe; and this Plutarch reckons to have been one cauſe of the declenſion of the oracle. The general characteriſtic of this as well as other oracles was obſcurity and ambiguity; ſo that the ſame anſwer might be differently interpreted and applied; though it has been ſaid that the anſwers of this oracle were more plain and determinate than thoſe of ſome others. Theſe, however, were on many occaſions equivocal. Thus, when Crœſus was about to invade the Medes, he conſulted this oracle upon the ſucceſs of the war, and received for anſwer, that by paſſing the river Halys, he would win a great empire. But he was left to conjecture, or to determine by the event, whether this empire was his own or that of his enemies. Such was alſo the ſame oracle's anſwer to Pyrrhus,

"Aio te, Æacida, Romanos vincere poſſe."

Under the cover of ſuch ambiguities, the god eluded all difficulties, and was never in the wrong. The prieſts and prieſteſſes, to whoſe conduct the reſponſes of the oracle were committed, were frequently guilty of fraud and impoſture. Many inſtances might be mentioned; the Delphic prieſteſs was not ſuperior to corruption. Hence ſhe perſuaded the Lacedæmonians to aſſiſt the people of Athens in the expulſion of the 30 tyrants. Hence alſo ſhe cauſed Demaratus to be diveſted of the royal dignity to make way for Cleomenes; and ſupported the impoſtor Lyſander, when he endeavoured to change the ſucceſſion to the throne of Sparta. It is not improbable, that Themiſtocles, who well knew the importance of acting againſt the Perſians by ſea, inſpired the god with the anſwer he gave, "to defend themſelves with walls of wood." Demoſthenes, convinced that the oracles were frequently ſuggeſted by paſſion or intereſt, and ſuſpecting, with reaſon, that Philip had inſtructed them to ſpeak in his favour, boldly declared, that the Pythia *philippized*, and bad the Athenians and Thebans remember, that Pericles and Epaminondas, inſtead of liſtening to, and amuſing themſelves with, the frivolous anſwers of the oracle, thoſe idle bugbears of the baſe and cowardly, conſulted only reaſon in the choice and execution of their meaſures. See ORACLE.

DELPHIN, in *Literary Hiſtory*. See DAUPHINS.

DELPHINIA, in *Antiquity*, feaſts which the inhabitants of Egina celebrated in honour of Apollo, ſurnamed Delphinius, ſo called, as it is pretended, becauſe he aſſumed the form of a dolphin to conduct Caſtalius and his colony from the iſle of Crete to the *Sinus Criſſæus Delphinium*, one of the courts of judicature of the Athenians; ſo called from the proximity of the place, where they held their aſſemblies, to the temple of Apollo Delphinius.

DELPHINIUM, in *Botany*, (Δελφινιον of the ancient Greeks, "becauſe," ſays Dioſcorides, "the ſlender ſegments of its leaves reſemble dolphins;" a reſemblance rather to be found, according to the vulgar idea of that fiſh, between the curvature of its body and the horned nectary of the flower; and Dodonæus ſuggeſts, on good authority, that the paſſage is ſo to be underſtood.) Linn. Gen. 274. Schreb. 367. Willd. Sp. Pl. v. 2. 1226. Juſſ. 234. Gærtn. t. 65. Claſs and

and order, *Polyandria Trigynia*. Nat. Ord. *Ranunculaceæ*, Juſſ. *Multiſiliquæ*, Linn. Larkſpur.

Gen. Ch. *Cal.* none, unleſs we, with Juſſieu, take the petals for ſuch. *Cor.* Petals five, unequal, placed in a circle, of which the upper one is extended at the baſe into a long, ſtraight, blunt, tubular ſpur: the two lateral ones are broadeſt, and the two lowermoſt leaſt of all. Nectary of two leaves, combined or diſtinct; its fore part ſurrounded by the petals; its tubular ſpur encloſed in that of the uppermoſt petal. *Stam.* Filaments numerous, 15—30, ſmall, awl-ſhaped, dilated at the baſe, aſcending towards the upper petal. Anthers erect, roundiſh, two-lobed, ſmall. *Piſt.* Germens three or one, ovate-oblong. Styles ſhort. Stigmas obtuſe, reflexed. *Peric.* Capſules equal in number to the germens, cylindrical, ſtraight, of one valve and one cell, burſting longitudinally along their inner edge. *Seeds* ſeveral, roundiſh, angular.

Eſſ. Ch. Calyx none. Petals five; the upper one ſpurred. Nectary cloven, with a poſterior ſpur.

The lower leaves are digitate or palmate; the upper ſometimes undivided. Flowers looſely ſpiked or panicled, terminal, various in colour, but never yellow. Juſſ.

Nine ſpecies of Larkſpur are enumerated in the 14th edition of Linn. Syſt. Veg. publiſhed by Murray, fourteen in Willdenow.

* *Capſules ſolitary.*

D. *Conſolida*, Sm. Fl. Brit. 577. Engl. Bot. t. 1839; "Capſule ſolitary. Nectary of one leaf. Stem ſubdivided;" is one of the annual ſpecies, abundant in the open fields of Cambridgeſhire, &c. and known in gardens by the name of Branching Larkſpur. Its Latin denomination aroſe from a miſtaken opinion of its healing or conſolidating virtues. The reverſe would be nearer the truth, its juices being, like thoſe of many kinds of *Ranunculus*, *Anemone*, and *Clematis*, ſo acrid as more or leſs to bliſter the ſkin. The flowers, naturally of a brilliant though deep blue, and forming with alum a blue pigment, are occaſionally white, pink, or elegantly variegated with pink and blue. D. *Ajacis*; "Capſule ſolitary. Nectary of one leaf. Stem ſimple;" is the more common Garden Larkſpur, ſo frequently double and ſo various in colour. Upon what foundation Linnæus and others have taken this for the hyacinth of the poets does not appear. The late profeſſor Martyn, and his ſon, the learned editor of Miller, contend, with great probability, that *Lilium Martagon* was the plant intended, on account of the letter-like marks on its petals, and profeſſor Heyne aſſents to this opinion. See Hyacinthus, Lilium, and Scilla. D. *aconiti*; Linn. Mant. 77. Vahl. Symb. v. 1. t. 13; "Capſule ſolitary. Nectary of one leaf, with four teeth in front. Ultimate branches ſingle-flowered." A very remarkable ſpecies on account of its minute petals and large nectary, found by Tournefort and Forſkall in the Levant, was referred by the latter to *Aconitum*.

** *Capſules Three to each Flower.*

Of this ſection the moſt remarkable are, D. *grandiflorum*, Mill. Ic. t. 250. f. 1.; Nectary two-leaved, with an undivided lip. Leaves in numerous linear acute ſegments. Root perennial. Flowers very large, of a rich deep blue. Capſules hoary. A native of Siberia, one of the fineſt of its genus. D. *elatum*, the common Bee Larkſpur, and D. *exaltatum*, the brilliant American Larkſpur, are both hardy perennials, frequent in our gardens, which may be made to bloſſom twice in one ſeaſon if cut down cloſe to the root after their firſt flowering. D. *Staphiſagria*, Staveſacre, Woodv. Med. Bot. t. 154, a native of the South of Europe, though a flower of great beauty, is chiefly known for its ſeeds as a vulgar remedy to expel lice. It is a biennial, rather difficult of culture.

Delphinium, in *Gardening*, compriſes plants of the herbaceous, flowery, hardy, annual, and perennial kinds; of which the ſpecies moſtly cultivated are the upright larkſpur (D. *ajacis*), the great flowered bee lark-ſpur (D. *grandiflorum*), and the tall bee lark-ſpur (D. *elatum*): Of which the firſt is annual, and has the ſtalks eighteen inches and more in height, ſeldom branched; the leaves are finely divided, commonly by threes, on broad petioles; the ſegments are linear, quite entire, and channelled above; the ſpikes of flowers erect, denſe, and of different colours.

There are varieties with ſingle and double blue flowers; with ſingle and double purple flowers; with ſingle and double ſilver-coloured flowers; with ſingle and double violet-coloured flowers; with ſingle and double aſh-coloured flowers; with ſingle and double ſtriped flowers; large rocket lark-ſpur, and dwarf or rocket lark-ſpur.

The ſecond ſort has a perennial root, which puts out two or three branching ſtalks every ſpring, riſing about a foot and a half high; the leaves are ſmooth and of a light green colour above, and hoary beneath, compoſed of many narrow ſegments, which terminate in ſeveral acute points; the flowers come out towards the upper part of the ſtalks ſingly, each on a long naked peduncle, are large, and of a fine azure colour. They appear in June and July, and the plant is a native of Siberia.

The laſt ſort riſes to the height of from five to ſix feet; the root is perennial; the leaves ſlightly villoſe, becoming ſmooth by age, half-five-lobed, petioled; lobes acute, often half-three-lobed, ſharply ſerrate. The ſpikes of flowers very long and handſome, of a deep blue colour, with a wrinkled ſpur. It is a native of Switzerland, &c. flowering from June to September.

Method of Culture.—Theſe plants, in all the ſorts and varieties, are propagated by ſowing the ſeeds in the early ſpring, as in February, March, and the following month, or in the autumn, immediately after the ſeeds become ripe, in the clumps, borders, or other places where the plants are to remain, as they do not ſucceed ſo perfectly by tranſplanting, in patches of eight or ten in a place, covering the ſeed into the depth of nearly half an inch, the mould being previouſly rendered fine.

Where the annual ſort and varieties are cultivated for a large ſhow, the ſeed may be ſown thinly in drills on beds four feet broad, at a foot diſtance, covering it into the above depth. They are ſometimes ſown in other forms, for the purpoſe of appearance.

The autumn ſowings of theſe ſeeds ſhould be marked, by placing ſmall ſticks in the places, to prevent their being diſturbed by the ſpring digging of the ground.

The only culture the plants in general require after they appear, is that of thinning them in a proper manner, according to circumſtances, and keeping them free from weeds. And in the perennial ſorts, removing the ſtems in the autumn.

Theſe plants afford much ornament and variety in the different compartments of pleaſure-grounds, and they ſucceed in moſt ſoils and ſituations, being of hardy growth.

Delphinium, in *Ancient Geography*, a maritime town of the iſle of Chios, ſituated eaſtward, and towards the middle of the iſland. It was taken by Callicratides, commander of the Lacedæmonians towards the ſecond year of the 93d olympiad, 407 years B. C.

DELPHINUS, the *Dolphin*, in *Aſtronomy*, a conſtella-

tion of the northern hemiſphere; whoſe ſtars, according to Ptolemy, are 10; according to Tycho, as many; according to Hevelius, 14; and, according to Mr. Flamſteed, 18.

Delphinus, in *Zoology*, the laſt genus of the cetaceous or fiſh-formed tribe of mammalia, the character of which conſiſts ſimply in having teeth in each jaw. By this means, it is at once diſtinguiſhed from the whale tribe, which have no teeth in either jaw, from the monodon, which have them only in the upper jaw, and the phyſeter, in which they occur only in the lower one. Theſe are the four genera of cetaceous animals. The ſpecies of the delphinus genus, four in number, are defined as follows.

Phocæna. Body ſub-conic, back broad, ſnout bluntiſh. Linn. Fn. Suec. *Turſio*, Pliny. *Meerſchwein oder tunin*, Mart. *Niſer ou le marſouin*, Egede. Porpoiſe, or Porpeſſe.

The upper part of the body in this kind is blueiſh black, and the lower white; the head obtuſe, with ſmall eyes and teeth (the latter of which are acute), and the vent ſomewhat bilobate. The porpeſſe inhabits the European ſeas, and not unfrequently in warm ſeaſons aſcends the entrance of large rivers, in purſuit of the ſhoals of fiſhes, which are proceeding in their migratory courſe from the ſea to the freſh waters. The porpeſſe lives chiefly on the ſmaller kinds of fiſh, and is obſerved, when in queſt of food, to turn up the ſand and mud at the bottom of the water like the hog: it is often ſeen, likewiſe, darting and tumbling over in the water like the dolphin, and this uneaſineſs of the animal, in the opinion of ſome, is to be regarded as the preſage of ſtormy weather.

Porpeſſes are obſerved to aſſemble occaſionally in vaſt numbers, and to purſue ſhoals of herrings, mackarel, and other fiſh, which they drive into the bays and cloſe receſſes, and prey upon with great voracity. This animal is remarkably fat, and being covered immediately under the ſkin with a very thick coat of lard, affords an abundance of oil. The porpeſſe was once conſidered as a ſumptuous article of food in this country, and was oftentimes introduced to the tables of the Engliſh nobility, even ſo lately as the reign of queen Elizabeth. It was eaten with a ſauce compoſed of the crumbs of fine bread with ſugar and vinegar. In the preſent day, the porpeſſe is an object of capture only for the ſake of its oil.

Delphinus. Body oblong, roundiſh; ſnout narrow and ſharp. Artedi. *Delphinus*, Pliny. *Porcus marinus*, Sibbald. *Delphin*, Crantz. Dolphin.

The dolphin bears a great reſemblance to the porpeſſe, but has a ſnout more elongated and acute, and the ſhape of the body throughout is rather more ſlender; and it alſo grows to a much larger ſize, the porpeſſe ſeldom exceeding three or four feet, and the dolphin meaſuring in common eight or ten feet; the colour is rather ſimilar in both. The dolphin is found in the Mediterranean and Indian ſeas, and ſeems to be generally confounded by navigators with the former. It preys on various kinds of fiſh, and is ſaid to be ſometimes ſeen attacking and wounding even the larger kinds of whales. The ſeamen conſider its appearance as the prelude of an approaching ſtorm.

The celebrity which the dolphin obtained among the ancients, from its ſuppoſed attachment towards the human race, is ſufficiently known. "The dolphin," ſays Pliny, "is friendly to man, and pleaſed with muſic. He does not fly from the ſight of mankind, but of his own accord meets their ſhips, gamboling before them, and accompanying their courſe, as if through a ſpirit of emulation, and always outſtripping them, even when ſailing with the moſt favourable wind." The voice of the dolphin, according to the ſame writer, is a ſound reſembling a human groan. Theſe and other particulars related by poets and hiſtorians of antiquity, have excited ſentiments of veneration in vulgar minds towards this uncouth inhabitant of the waters: as poetic allegories, thoſe tales are not diſpleaſing; but as matters of fact are altogether diſcountenanced by the obſervations of later writers.

From the teſtimony of Gronovius, it appears, that the porpeſſe conſtantly ſwims in an incurvated poſture; and this very naturally leads to a concluſion that the dolphin, whoſe form is ſtrikingly ſimilar, may ſwim in the ſame poſition; a circumſtance tending to prove that the repreſentations of the dolphin, tranſmitted to us by the ancients, are not ſo greatly exaggerated as might otherwiſe be imagined.

Orca. Snout turning upward; teeth obtuſe. *Delphinus orca, roſtro ſurſum repando, dentibus latis ſerratis*, Linn. Mant. *Orca*, Pliny. *Butſkopf*, Marten. *Buts-kopper*, Egede. Grampus.

This animal grows to the length of twenty-five feet, and is of an extremely fierce and predatory diſpoſition, feeding on larger fiſhes, and even on the dolphin and the porpeſſe. It is found in the Mediterranean and Atlantic ſeas, as well as in both the polar regions. This ſpecies often attacks the whales, whence Fabricius denominates it *balænarum tyrannus*. Seals are its more common food; theſe it frequently ſurpriſes while ſleeping on the rocks, diſlodging them by means of its back fin, and, having precipitated them into the water, ſeizes upon and devours them without difficulty.

Leucas. Snout conic, obtuſe, and inclining upwards; no dorſal fin. Pallas. *Beluga*, Penn. *Bieluga*, Steller. *Wittfiſch oder Weiſſfiſch*, Anderſon. *Weiſſfiſch*, Crantz.

A native of the arctic regions, deſcribed by Fabricius, Pallas, and other late writers, for it does not appear to have been diſtinctly known till within a few years. Its form is not inelegant, and its colour, when full grown, milk-white, or white, tinged with pale roſy. The ſpecies is gregarious, and is often obſerved ſwimming in large ſhoals, the young accompanying the parents, and the whole, from their unuſual colour, forming an intereſting ſpectacle. The head of this ſpecies is rather ſmall, and has the ſpiracle at the ſummit; the eyes very ſmall and blueiſh; the gape moderate; the teeth ſmall, blunt, and not very numerous, amounting to about ten on each ſide in both jaws. The neck is ſhort, and the body thickeſt in the middle. The tail is ſlightly lobed, the pectoral fins thick and fatty, and are marked at the edge into five ſlight diviſions: theſe contain the bones of the five fingers which may eaſily be felt within the fin. The ſkin, on every part, is ſmooth and ſlippery, and the animal in general very fat.

According to Pallas, when this animal ſwims, the tail is bent inwards, in the manner of the craw-fiſh, and is enabled to move in the water with amazing velocity by the alternate incurvation and extenſion of that part. It bears ſuch a ſtrong affinity with the ſeals, that the Samoieds conſider it as a kind of aquatic quadruped. This animal produces only one at a birth; this is at firſt blueiſh, grey, or inclining to blackiſh, and acquires the pure and beautiful milky white appearance of the parent as it advances in age.

DELPHOS. See Delphi.

DEL-REY, in *Geography*, a captainſhip, or province, in the ſouthern part of Brazil; which ſeems to be rather regarded as a frontier diſtrict towards the Spaniſh poſſeſſions, than as a regular ſettlement.

DELRIO, Martin-Anthony, in *Biography*, a learned Jeſuit, born at Antwerp in the year 1551. Having attained

to

to a competent knowledge of the claſſics, he went to Paris to be inſtructed by able profeſſors in rhetoric and philoſophy. From Paris he proceeded to Douay and Louvain to ſtudy the law, and thence he travelled to Spain, where, in 1574, he had the degree of doctor conferred on him by the univerſity of Salamanca. On his return into the Low Countries he filled ſome civil offices of honour and emolument; but upon the breaking out of the wars in Flanders, he took another journey into Spain, when he entered himſelf among the Jeſuits at Valladolid, in the year 1580. In a few years he was ordered by his ſuperiors into the Low Countries, to teach philoſophy, the languages, and theology. At Louvain he contracted an intimacy with the celebrated Juſtus Lipſius. Here he died in October 1608. As an author he is chiefly known by his "Diſquiſitiones Magicæ," in three vols. 4to. publiſhed in 1599 and 1601. He publiſhed likewiſe commentaries on various parts of the Old and New Teſtaments; and treatiſes in defence of the genuineneſs of the books attributed to Dionyſius, the Arcopagite, againſt the criticiſms of Scaliger. In the early part of life he publiſhed notes on Claudian, on the tragedies of Seneca, together with ſome treatiſes on law. Moreri.

DEL Spiritu Santo, in *Geography*, a river which falls into the gulf of Mexico, at the N. W. end of the peninſula of Florida.

DELTA, the name given to a conſiderable part of Lower Egypt, on account of its triangular figure, which reſembles the Greek *delta*, Δ. The triangle which formed the delta was anciently compriſed between two branches of the Nile, and the Mediterranean ſea. At ſome diſtance to the north of Memphis, or at a place where formerly ſtood the town of "Cerceſura," now called "Batn el Bakara," or the cow's belly, the Nile ſeparated into two principal branches, *viz.* the Canopic branch to the weſt, which falls into the ſea near Roſetta, and the Peluſian to the eaſt, which diſcharges itſelf into the ſea near Damieta. The former of theſe branches taking a north and north-weſt courſe, bore the name of "Agathosdæmon flumen," or the river of the good genius; and terminated to the eaſt of Canopus, after having watered Schedia, which was ſituated at the mouth called "Canopicum Oſtium." The latter branch, whoſe courſe was north-eaſt, was called "Athribiticus fluvius," becauſe it watered the town of "Athribis," and diſcharged itſelf into the ſea, near Peluſium, at the mouth denominated "Peluſiacum Oſtium." The ſpace comprehended between theſe two branches was divided into two others; one called Delta, which compriſed the territory between the Agathoſdæmon and the continuation of the Athribiticus, paſſing by Xoïs, Buſiris, &c. to Thumiathis, where was the mouth called "Phatmeticum Oſtium." The other part, comprehended between this branch and that which turned towards the eaſt from the north of Athribis as far as Peluſium, was called "Delta parvus." The firſt of theſe Deltas contained the towns of Proſopitis, Taula, Saïs, Buſiris, Xoïs, Sebenythus, Onuphis, Pachnamunis, Butus, and Metelis, which gave name to as many different nomes, beſides other conſiderable towns; the Parvus Delta contained the towns of Leontopolis, Mendes, Panephyſis, Tanis, and Sethrum, together with ſome others which were not the capitals of nomes. Conſidering, ſays major Rennell in his "Geographical Syſtem of Herodotus examined and explained," the extreme flatneſs of the Delta; the quality of its ſoil which is totally different from that of the adjacent countries; its form which projects ſo far into the ſea, beyond the general line of the coaſt, on the one hand, and on the other, filling up a ſpace which, reaſoning from appearances, looks like a bay or gulf of the ſea: one can hardly doubt, that the ſpace which it occupies was originally a part of the ſea, from the neighbourhood of Peluſium, or of mount Caſius, to that of Alexandria; and ſouthward to the foot of the hills of the pyramids, and of Mokattam; which is allowing little more for the depth of the bay, from the ſuppoſed line of the coaſt, than the lower point of the Delta now advances beyond it. Without doubt when we carry back our ideas to the time when the ſea waſhed the baſe of the rock, on which the pyramids of Memphis ſtand, the preſent baſe of which is waſhed by the inundation of the Nile, at an elevation moſt probably of 70 or 80 feet above the ſurface of the ſame ſea; we are loſt in the contemplation of the vaſt interval of time that muſt neceſſarily have elapſed ſince the foundation of the Delta was firſt laid. To the natural progreſs of alluvion, the depoſitions acquire a maſs capable of ſeparating the parent river into different channels, by an apex; while, the ſides ſpreading wider as they recede from this point, the newly emerged land aſſumes a triangular form. Its baſe gradually enlarges by new depoſitions; the maſs, as it acquires a firmer conſiſtence, confines the river to fewer channels; and the apex of the Delta changes its poſition by receding farther from the ſource. In this way M. Rennell ſtates grounds for ſuppoſing that the apex of the Delta of Egypt was once ſituated to the ſouthward of the ſite of Memphis: and he produces leſs equivocal teſtimony of a change of poſition towards the north, in times poſterior to that diſtant and doubtful era. The ſite of the centre of ancient Memphis is placed by Mr. Rennell in 29° 53′. The Canopic, or moſt weſtern branch of the Nile, is ſuppoſed to have gradually forſaken its bed, and to occupy the Bolbitine channel, which was originally an artificial one. By this change, the Delta has been contracted about 18 miles of the weſtern part of its baſe; and this is become as barren a deſert as the adjoining one of Libya. The opinion above ſtated, that the Delta has been formed by the accumulation of ſlime or ſoil in conſequence of the periodical inundations of the Nile, is now very generally received by naturaliſts; though it is liable to ſome very ſtrong objections from chronology, which are not eaſily ſolved. If the ſea ever waſhed the rock on which the pyramids ſtand, it muſt have been at a period much anterior to the building of Memphis by Menes; ſince the gradual depoſition of the river had even then produced the Delta. Yet Menes muſt have lived only a few centuries ſubſequent to the flood. Another phyſical objection occurs of ſtill greater weight. There was a time when the rock of the pyramids was nearly on a level with the ſea; it is now 80 feet above that level, not by the retroceſſion of that element, but by the acceſſion of height gained by the land in conſequence of the depoſitions of the Nile, according to the opinion above ſtated. Let us ſuppoſe, then, that when the city of Memphis and the pyramids were founded, the ſite was 40 feet above the level of the ſea; in this caſe, Memphis, the pyramids, and of courſe, many of the cities of ancient Egypt, would now be 40 feet under ground;—a ſuppoſition not warranted by fact. In the time of Moeris, who is ſaid to have lived 500 years before the Trojan war, the Delta appeared in its infancy. Eight cubits were then ſufficient to overflow it in its whole extent. Boats paſſed over it from one extremity to the other, and its towns, built on artificial elevations, reſembled the iſlands of the Ægean ſea. (Herodotus, Euterpe. Strabo, lib. xvii.) When Herodotus viſited Egypt, 15 cubits were neceſſary to cover all the Lower Egypt, but the Nile then overflowed the country for the ſpace of two days' journey, to the right and left of the Delta. Under the Roman empire, 15 cubits produced the ſame effect. In the time of the domination of the Arabs, their writers ſpeak of 17 cubits as the moſt favourable height. Eighteen cubits are at this time

time the meaſure of abundance; but the inundation no longer extends over the Lower Egypt, but its progreſs is ſtopped at Grand Cairo, and in the neighbouring country. The Nile, however, ſometimes riſes to 22 cubits. The mud accumulated for ſo many years on the iſland, which aroſe from out of its boſom, is the cauſe of this phenomenon. Art has alſo contributed towards it, either by the banks raiſed to protect the lands moſt expoſed to the action of the river, or by multiplying its outlets, and by cutting a great number of canals, which give a free paſſage to the waters. The Delta, which is ninety leagues in circumference, is at preſent in the moſt favourable ſtate for agriculture. Waſhed on the eaſt and weſt by two rivers formed by the diviſion of the Nile, and interſected by innumerable rivulets, it preſents to the eye an immenſe garden, all the different compartments of which may be eaſily watered. During the three months that the Thebais is under water, the Delta poſſeſſes fields covered with rice, barley, vegetables, and winter fruits. It is no longer, as in former times, the Ægean ſea with the Cyclades; rich harveſts now cover an extenſive plain; it is now overſpread with groves of date-trees, of oranges, and ſycamores; here are perpetually running ſtreams, and a verdure that is conſtantly varied and renewed; it is, in ſhort, ſays M. Savary, (Letters on Egypt, vol. i.) a picture of abundance, that delights the eye, and aſtoniſhes the imagination. By loſing the inundation, this iſle has gained every year, the three months during which the Thebais is under water. It is alſo the only part of Egypt, where the ſame field produces two crops of grain within the year, one of rice, the other of barley. The length of the Delta, as well as its height, has increaſed. (Strabo. lib. xvii.) Under the reign of Pſammetichus, the Mileſians, with 30 veſſels, landed at the mouth of the Bolbitine branch, now called that of Roſetta, where they fortified themſelves. They there built a town called "Metelis," the ſame as Faoüe. This town, formerly a ſea-port, is at preſent 9 leagues diſtant from it, and this is the ſpace by which the Delta has lengthened, from the time of Pſammetichus to our day. Moreover, the new town of Alexandria is at ſome diſtance to the north of the ruins of the old town, and the ſea has retired. (See ALEXANDRIA and PHAROS.)

Some Arabs divide the Delta into two parts "Al Rif," and "Al Bahriya;" the former, being the weſtern part, is ſuppoſed by Bochart to be the Rahab of the Scriptures, and was ſo called becauſe of its form, reſembling a pear; which the Egyptians call Rib, or Ribi. Al Bahriya is the eaſtern part of the Delta, in the opinion of many; though Sicard more truly places Al Bahriya, or as he writes it, Beheiré, beyond the weſtern branch of the Nile. Delta, as Savary informs us, is divided into two provinces, in which two Beys reſide. Menouf is the capital of the Upper, and Mehallé el Kebire of the lower province; the former is called Menoufié, and the latter Garbie.

DELTA, a town of Egypt, in the greater Delta, according to Ptolemy.—Alſo, a name given to a quarter of Alexandria.

DELTA *of the Ganges*, that part of the province of Bengal which lies near the mouth of the Ganges, commencing about 220 miles from the ſea, or 300 by the windings of the river, and comprehending conſiderably more than twice the area of that of the Nile.

The two weſternmoſt branches, named the Coſſimbuzar and Jellinghy rivers, unite, and form what is afterwards called the Hoogly river; which forms the port of Calcutta, and the only branch of the Ganges that is commonly navigated by ſhips. That part of the Delta, which borders on the ſea, is compoſed of a labyrinth of rivers and creeks, all of which are ſalt except thoſe that immediately communicate with the principal arm of the Ganges. This tract, known by the name of the "Woods," or "Sunderbunds," is in extent equal to the principality of Wales; and is ſo completely inveloped in woods, and infeſted with tigers, that if any attempts have ever been made to clear it, they have hitherto miſcarried. Its numerous canals are ſo diſpoſed as to form a complete inland navigation throughout and acroſs the lower part of the Delta; without either the delay of going round the head of it, or the hazard of putting to ſea. Here ſalt, ſufficient for the whole conſumption of Bengal and its dependencies, is made and tranſported with equal facility; and here is alſo formed an inexhauſtible ſtore of timber for boat-building. The breadth of the lower part of this Delta is upwards of 150 miles; to which, if we add that of the two branches of the river that bound it, we ſhall have about 200 miles for the diſtance to which the Ganges expands its branches at its junction with the ſea. In tracing the ſea-coaſt of the Delta, there are found no leſs than eight openings; each of which, without heſitation, one pronounces to have been in its time the principal mouth of the Ganges. Nor is the occaſional deviation of the principal branch, probably, the only cauſe of fluctuation in the dimenſions of the Delta. The deltas of moſt capital rivers, the tropical ones eſpecially, are obſerved to encroach upon the ſea. This circumſtance is probably owing to the mud and ſand brought down by the rivers, and gradually depoſited, from the remoteſt ages down to the preſent time. The rivers, it is known, are loaded with mud and ſand at their entrance into the ſea; and it is alſo known, that the ſea recovers its tranſparency at the diſtance of 20 leagues from the coaſt; which muſt be owing to the waters having precipitated their earthy particles within that ſpace. As a ſtrong preſumptive proof of the wandering of the Ganges from one ſide of the Delta to the other, major Rennell obſerves, that there is no appearance of *virgin* earth, between the Tiperah hills on the eaſt, and the province of Burdwan on the weſt; nor on the north till we arrive at Dacca and Bauleah. In all the ſections of the numerous creeks and rivers in the Delta, nothing appears but ſand and black mould in regular ſtrata, till we arrive at the clay, that forms the lower part of their beds. There is not any ſubſtance ſo coarſe as gravel, either in the Delta, or nearer the ſea than 400 miles, at Oudanulla, where a rocky point, a part of the baſe of the neighbouring hills, projects into the river: but in places remote from the great rivers, the ſoil is either red, yellow, or of a deep brown. Rennell's Memoir, Phil. Tranſ. vol. lxxi. p. 92, &c.

DELTA *of the Indus*, a part of the province of Sinde, formed by the mouths of the river Indus or Sinde, near its entrance into the ſea, and projecting into the ſea, inſtead of receding from it. We learn from major Rennell, that during great part of the S.W. monſoon, or at leaſt in the months of July, Auguſt, and part of September, which is the rainy ſeaſon in moſt other parts of India, the atmoſphere in the Delta of the Indus is generally clouded; but no rain falls, except very near the ſea. Indeed, very few ſhowers fall during the whole ſeaſon.

The Ava or Pegue river forms likewiſe a delta of conſiderable extent. Thus alſo the Kiſtnah and Godavery rivers, however remote at their fountains, approach within 80 miles of each other, in the lower parts of their courſe; and form an extenſive tract of country, compoſed of rich vegetable mould, ſuch as is uſually found at the mouths of large rivers. By comparing this tract with the Deltas of Egypt and Bengal, and reaſoning from analogy, it will be readily ſuppoſed, that the whole, or the greateſt part of the territory included between Samulcotta and Pettapolly, about 150 miles in length

length along the ſea-ſhore, and from 40 to 50 wide, is in reality a gift of the two fore-mentioned rivers. The ſame appearances may be obſerved at the mouths of the Cattack and Tanjore rivers; but the Kiſtnah and Godavery, by draining a much greater extent of country, that is, from the 15th to the 21ſt degree of latitude, have collected materials for a greater quantity of new land. Within this new-formed land, and about mid-way between the Godavery and Kiſtnah, the ſoil forms a hollow ſpace, which in its loweſt part is a lake at all ſeaſons; and in all the other parts an extenſive inundation, during the ſeaſon of the periodical rains; being then a lake of 40 or 50 miles in extent, and called the *Colair* Lake; which ſee. For an account of a ſimilar delta, ſee ZAMBEZI.

DELTHANII, in *Ancient Geography*, a town of the Peloponneſus, placed by Steph. Byz. between Laconia and Meſſenia.

DELTOIDES, in *Anatomy*, one of the large muſcles of the arm, ſo called becauſe its form is triangular, and therefore reſembles that of the capital delta of the Greek alphabet; (from δελτα, and ειδος, *form.*) It is a thick and fleſhy muſcle, forming the upper and outer part of the ſhoulder; ariſing by its broadeſt portion, which correſponds to the baſe of the triangle, from the ſcapula and clavicle, ſtretching over the head of the humerus, and, after gradually contracting in breadth, ending by a pointed inſertion into the humerus. Its origin takes place, by a mixture of tendinous and fleſhy fibres, from the whole length of the inferior margin of the ſpine of the ſcapula; from the outer convex edge of the acromion; and from one-third of the anterior margin of the clavicle; in that part which is towards the ſcapula. From theſe different points the fibres all deſcend, and converge to one inſertion; the poſterior portion paſſes very obliquely forwards, the middle of the muſcle is firſt bent over the head of the humerus, and then deſcends in a ſtraight courſe; and the anterior part proceeds obliquely backwards. The inſertion takes place, by means of a ſtrong tendon, more viſible on the inner than on the outer ſurface, into a large tuberoſity ſituated on the external, and rather above the middle part of the humerus. It extends about an inch and a half from above downwards, and is included by the bifurcation of the brachialis internus. The deltoid muſcle is covered on its external ſurface for the moſt part by the ſkin; but throughout a ſmaller portion, near its upper and anterior part, by the latiſſimus colli. On the inſide it is in contact behind with the infra-ſpinatus, tores minor, and the long head of the triceps near its origin; towards the middle, with the tendon of the ſupra-ſpinatus, the coraco-acromial ligament, the capſule of the ſhoulder-joint, the upper part of the humerus, and the circumflex veſſels and nerves; on the front, with the coracoid proceſs of the ſcapula, the tendon of the pectoralis minor, the biceps, coraco-brachialis, ſub-ſcapularis, and tendon of the pectoralis major. The cephalic vein of the arm lies along its anterior edge, being placed between it and the correſponding margin of the pectoralis major.

The fibres of the deltoid muſcle are arranged in large faſciculi, ſeparated from each other on the ſurface of the muſcle, and terminating in a pointed form below. Between the capſule of the humerus, the under ſurface of the acromion, and the deltoid, a large burſa mucoſa is found, which becomes particularly neceſſary here, on account of the friction created by the numerous and extenſive motions of the os humeri.

This muſcle will move the humerus or the ſcapula, according as the one or the other of theſe parts is the moſt moveable. The latter muſt in the great majority of inſtances be regarded as the fixed point. Suppoſing the arm to hang by the ſide of the body, the deltoid will raiſe it; either ſo as to bring it to a right angle with the ſide, or to carry it towards the front or back part of the trunk, according as the middle, the anterior or poſterior fibres are employed in the elevation. When the arm has been raiſed, the clavicular fibres will carry it towards the ſternum, and the ſcapular fibres towards the back: the latter at the ſame time depreſs the arm, if it has been carried upwards beyond the level of the ſpine of the ſcapula. When the arm is drawn up from the ſide in the mid direction between the anterior and poſterior, the elevation begins by the middle fibres of the deltoid, for the anterior and poſterior portions then acting together would draw the arm ſtill cloſer to the ſide; and either of theſe parts, being employed ſeparately, would incline the limb forwards or backwards. But, as the elevation proceeds, more and more of the fibres come into action; until at laſt the whole muſcle is employed. In elevating the arm, the deltoid is aſſiſted by the ſupra-ſpinatus muſcle, which ſee. When the humerus is fixed, the deltoid will draw the ſcapula towards that bone; and, as the latter part is united by various muſcles to the trunk of the body, the deltoid will concur in moving the trunk upon the upper limbs.

DELTOIDEUM FOLIUM. See LEAF.

DELTOTON, a conſtellation, the ſame as the *Northern* TRIANGLE, which ſee.

DELUBRUM, in *Roman Antiquity*, a temple with a large ſpace of conſecrated ground round it. See TEMPLE.

DELVE, in *Agriculture*, a term ſometimes employed to ſignify to dig with a ſpade.

DELUGE, DILUVIUM, in *Natural Hiſtory*, a flood, or inundation of water, covering the earth, either in the whole or part.

We meet with divers accounts of deluges in ancient hiſtory, both ſacred and profane: that which happened in Greece, in the time of Deucalion, called diluvium Deucalioneum, is famous: this deluge only overflowed Theſſaly. Its date is fixed to the year before Chriſt 1529, being the third year before the Iſraelites' coming out of Egypt, according to the computation of Petavius, Rat. Temp. par. i. lib. i. cap. 7. or according to Blair's Tables, about 1503 years B. C. See DEUCALION.

The deluge of Ogyges happened about 269 years before that of Deucalion, 1020 years before the firſt Olympiad, and 1796 before Jeſus Chriſt, according to the ſame author, Rat. Temp. par. i. lib. i. cap. 4. par. ii. lib. ii. cap. 5. or according to Blair, 1764 years B. C. (See OGYGES.) This only ravaged Attica.

Theſe two deluges are frequently mentioned, in ancient Greek authors, under the denomination of cataclyſmus prior and poſterior. Deucalion's flood in Theſſaly, and alſo thoſe of Ogyges in Attica, and of Prometheus in Egypt, have been thought the ſame with that of Noah.

Of the like kind were the deluge in Syria, which, in 1095, drowned a prodigious number of people; a deluge in Frieſland, which, in 1164, covered the whole environs of the coaſts, and drowned ſeveral thouſands of the inhabitants; another inundation in 1218, which deſtroyed 100,000 men; the inundations in the Netherlands, which, in 1727, overwhelmed and covered with ſea all that part now called the Gulf Dollart, in the United Netherlands; and in 1421, all that part between Brabant and Holland.

But the moſt memorable deluge is that which we particularly, by way of eminence, call the deluge, or the univerſal deluge, or Noah's flood; recorded in Scripture as a general inundation ſent by God to puniſh the corruption of the world,

world, at that time, by deſtroying every thing (Noah and his family, and what was ſhut up with him in the ark, only excepted) from the face of the earth.

This flood makes one of the moſt conſiderable epochas in chronology. Its hiſtory is given by Moſes, Gen. ch. vi. and vii. Its time is fixed by the beſt chronologers to the year from the creation 1656, anſwering to the year before Chriſt 2348. On the 10th day of the ſecond month, which was on Sunday November the 30th, God commanded Noah to enter into the ark with his family, &c.; and on Sunday December 7th, it began to rain, and rained 40 days, and the deluge continued 150 days. On Wedneſday May 6th, B. C. 2348, the ark reſted on mount Ararat. The tops of the mountains became viſible on Sunday July the 19th, and on Friday December the 18th, Noah came forth out of the ark with all that were with him; he built an altar and ſacrificed to God for his deliverance. (Blair's Chronology.) From this flood, the ſtate of the world is divided into diluvian, or poſtdiluvian, and antediluvian.

The account given by Moſes of this cataſtrophe, is confirmed by the concurrent teſtimonies of ſeveral of the moſt ancient writers and nations in the world; and as the poſſibility of it cannot be denied, we need not recur to the hypotheſis of an ingenious biblical critic (ſee Geddes's Crit. Rem. p. 72.) who ſuggeſts, "that a good deal of the fabulous is mixed with the hiſtory of Noah's flood." Although the hiſtory of this event has been varied, and modelled according to the notions and traditions that prevailed in different countries and different ages, yet the ground-work was always eſtabliſhed on the foundation of truth; and the event was for a long time univerſally commemorated. Joſephus, who ſeems to have been a perſon of extenſive knowledge, and well acquainted with the hiſtories of nations, ſays, that this great occurrence was to be met with in the writings of all perſons who treated of the firſt ages. He mentions Beroſus of Chaldæa, Hieronymus of Egypt, who wrote concerning the antiquities of Phœnicia; alſo Mnaſeas, Abydenus, Melon, and Nicolaus Damaſcenus, as writers, by whom it was recorded; and adds, that it was taken notice of by many others. From Beroſus, a Chaldæan by birth, who lived in the time of Alexander the Great, we learn, that Chronus or Saturn appeared to Xiſuthrus, the tenth or laſt of the Chaldæan kings, in a dream, and warned him, that on the 15th of the month Deſius, mankind would be deſtroyed by a flood; he therefore commanded him to write down the original, intermediate ſtate, and end of all things, and bury the writings under ground in Sippara, the city of the Sun; he likewiſe directed him to build a ſhip, and go into it with his relations and deareſt friends, having firſt furniſhed it with proviſions, and taken into it fowls and four-footed creatures; and told him, that when he had provided every thing, and was aſked whither he was ſailing, he ſhould anſwer, "to the Gods, to pray for happineſs to mankind." Xiſuthrus accordingly built a veſſel, whoſe length was five furlongs, and breadth two furlongs. He put on board all that he was directed to provide, and went into it with his wife, children, and friends. The flood being come, and ſoon ceaſing, Xiſuthrus let out certain birds, which, finding no food nor place to reſt upon, returned again to the ſhip. After ſome days he ſent forth the birds again, but they came back to the ſhip, having their feet daubed with mud; but when they were ſent away the third time, they returned no more: a circumſtance from which Xiſuthrus underſtood that the earth had appeared again. He now made an opening between the planks of the ſhip, and ſeeing that it reſted on a certain mountain, came out with his wife, his daughter, and his pilot; having worſhipped the earth, and raiſed an altar, and ſacrificed to the gods, he, and thoſe who went out with him, diſappeared. They who were left behind in the ſhip, finding Xiſuthrus, and the perſons that accompanied him did not return, went out to ſeek for him, calling him aloud by his name; but Xiſuthrus was no more ſeen by them; only a voice, iſſuing from the clouds, enjoined them to be religious, declaring that Xiſuthrus, on account of his piety, was gone to dwell with the gods; and that his wife, and daughter, and pilot, were partakers of the ſame honour. It alſo directed them to return to Babylon, and taking the writings from Sippara, to communicate them to mankind; and finally told them, that the place where they were was the country of Armenia. Thus informed, they offered ſacrifices to the gods, and immediately repaired to Babylon, dug up the writings at Sippara, built many cities, raiſed temples, and rebuilt Babylon. Abydenus alſo gives a ſimilar relation. It is ſaid that Xiſuthrus or Siſithrus, Ogyges, and Deucalion, are all names ſignifying the ſame thing in other languages, as Noah does in the Hebrew, in which Moſes wrote. (Vide Alexander. Polyhiſtor. ex Beroſo, apud Syncell. p. 30, 31. et apud Cyrill. contra Julian. l. 1. p. 8. Abydenus ex eodem, apud Syncell. p. 38, 39, et apud Euſeb. de Præp. Evang. l. ix. c. 12.) The Indians and Perſians had alſo traditions concerning the deluge. Accordingly, an eaſtern writer tells us, that ſome of thoſe who embrace the Magian religion, are ſaid to deny the flood, or at leaſt the univerſality of it; pretending that it reached no farther than a cliff near Hulwan, a city of Irak, bordering on Curdiſtan. Nevertheleſs the orthodox among them acknowledge this general deſtruction by water, ſent by God to puniſh the crimes of mankind: one of whom, named Malcus, was a monſter of wickedneſs and impiety. One odd circumſtance mentioned by them is, that the firſt waters of the deluge guſhed out of the oven of a certain old woman, named Zala Cuſa: and Mahomet has borrowed this circumſtance, and inſerted it in his Koran; the commentators on which ſay, that it was the ſign by which Noah knew the flood was coming. (Al Koran, cap. xi. D'Herbelot. Bib. Orient. Hyde de Rel. Vet. Perſ. c. x.) Lord's account of the religion of the Perſes, p. 9.

Plutarch (De Solert. Anim. v. ii. p. 968.) mentions the Noachic dove, and its being ſent out of the ark; and its going out was to Deucalion a ſign of fine weather, as its return denoted the reverſe. Melo, or Melon, who wrote a treatiſe againſt the Jews, (ſee Euſeb. Præp. Evang. l. ix. c. 19.) takes notice, among other things, of the perſon who ſurvived the deluge, retreating with his ſons, after the calamity from Armenia; and he ſuppoſes that they came to the mountainous parts of Syria, inſtead of the plains of Shinar. This writer ſeems to repreſent the deluge as topical, and not to have reached Armenia.

That the Egyptians were no ſtrangers to the deluge appears, not only from ſeveral circumſtances in the hiſtory of Oſiris and Typhon, particularly the very day when it began, or when Oſiris, (who is taken for Noah) was ſhut up in the ark, and the name of Typhon, which, according to ſome learned men, ſignifies a deluge or inundation; but alſo from the teſtimony of Plato, who ſays, that a certain Egyptian prieſt recounted to Solon, out of their ſacred books, the hiſtory of the univerſal flood, which happened long before the particular inundations known to the Grecians. It is the tradition of the Egyptians, as we learn from Diodorus Siculus (lib. i.) that the univerſal deluge was that of Deucalion. But the moſt particular hiſtory of the deluge, and the neareſt of any to the account given by Moſes, is to be found in Lucian. (De Dea-Syria, vol. ii. p. 882.) He was a native of Samoſata, a city of Comagene upon the Euphrates; a part of the world where memorials of the deluge were particularly preſerved, and where a reference to that hiſtory is continually to be obſerved in the rites and worſhip of the country.

try. His knowledge was therefore obtained from the Aſiatic nations, among whom he was born. He deſcribes Noah under the name of Deucalion, and ſays, that "the preſent race of mankind are different from thoſe who firſt exiſted; for thoſe of the antediluvian world were all deſtroyed. The preſent world is peopled from the ſons of Deucalion having increaſed to ſo great a number from one perſon. In reſpect to the former brood, they were men of violence, and lawleſs in their dealings. They regarded not oaths, nor obſerved the rites of hoſpitality, nor ſhewed mercy to thoſe who ſued for it; on this account they were doomed to deſtruction; and for this purpoſe there was a mighty eruption of waters from the earth, attended with heavy ſhowers from above, ſo that the rivers ſwelled, and the ſea overflowed, till the whole earth was covered with a flood, and all fleſh drowned. Deucalion alone was preſerved to re-people the world. This mercy was ſhewn to him on account of his juſtice and piety. His preſervation was effected in this manner: he put all his family, both his ſons and their wives, into a vaſt ark, which he had provided; and he went into it himſelf. At the ſame time animals of every ſpecies, boars, horſes, lions, ſerpents, whatever lived upon the face of the earth, followed him by pairs, all which he received into the ark, and experienced no evil from them; for there prevailed a wonderful harmony throughout, by the immediate influence of the Deity. Thus were they wafted with him, as long as the flood endured." After this he proceeds to mention, that upon the diſappearing of the waters, Deucalion went forth from the ark, and raiſed an altar (altars, according to Gen. vi. 20.) to God: but he tranſpoſes the ſcene to Hierapolis in Syria, where the natives pretended to have very particular memorials of the deluge. Moſt of the authors, who have tranſmitted to us theſe accounts, inform us at the ſame time, that the remains of the ark were to be ſeen in their days upon one of the mountains of Armenia. Abydenus ſays, that the people of the country uſed ſmall pieces of the wood as amulets; and Beroſus ſays the ſame of the aſphaltus, with which it was covered, and which they ſcraped off.

The learned Bryant, in his "Analyſis of Ancient Mythology," (vol. ii.) has traced out a reference to Noah and the deluge, and a reſemblance of the ark, in many of the religious rites and ceremonies of ancient nations. The well-known ſhip of Iſis, among the Egyptians, was, as he conceives, a ſacred emblem; in honour of which theſe people celebrated an annual feſtival. It was, in after-times, admitted among the Romans, and ſet down in their calendar for the month of March. The temple of Oſiris (or Seſoſtris) at Theba was built after the model of a ſhip, 280 cubits in length; and both the city, ſaid to be the moſt ancient in Egypt, as well as the province, was denominated from the ark, called תבה, Theba, by the ſacred writer. The ſame memorial is to be obſerved in other countries, where an ark, or ſhip, was introduced in their myſteries, and often carried about upon their feſtivals; and many inſtances of emblematical repreſentations are cited by Bryant, which related to the hiſtory of the deluge, and the conſervation of one family in the ark. This hiſtory was pretty recent, when works of this kind were executed in Egypt, and when the rites to which they belonged were firſt eſtabliſhed; and this learned writer imagines, that in early times moſt ſhrines among the Mizraim were formed under the reſemblance of a ſhip, in memory of this great event. He adds further, that both ſhips and temples received their names from hence; being ſtyled by the Greeks, who borrowed largely from Egypt, Ναυς and Ναος, and Mariners Ναυται, Nautæ, in reference to the Patriarch, who was variouſly ſtyled Noas, Naus, and Noah. Plutarch (Iſis and Oſiris, vol. i. p. 366, 367.) gives us a remarkable account of Oſiris being expoſed in an ark. He ſays, that it was on account of Typhon; and that it happened on the 17th of the month Athyr, when the ſun was is Scorpio. "This in my judgment;" ſays Bryant, "was the preciſe time, when Noah entered the ark, and when the flood came; which in the Egyptian mythology was termed Typhon." From theſe, and many other circumſtances that might be recited, it ſufficiently appears, that the hiſtory of the deluge was no ſecret to the Gentile world. They held the memory of it very ſacred; and many colonies which went abroad, ſtyled themſelves Thebeans, in reference to the ark; and many cities of the name of Theba occur, not in Egypt only and Bœotia, but in Cilicia, Ionia, Attica, Phthiotis, Cataonia, Syria, and Italy.

The tradition of the deluge has, indeed, ſpread throughout the world, and is preſerved in the memory of all nations; in the continent of America, as well as Aſia, in the Eaſt and Weſt Indies, among the Africans and Europeans. (See Burneti Telluris Theor. Sacra. l. i. c. 3)

We are told, indeed, (ſee Code of Gentoo Laws, Pref. p. 38.) that the Gentoo ſcriptures make no mention of the deluge; and that the Bramins affirm, that the deluge never took place in Hindooſtan. If this be true, it may well excite aſtoniſhment, ſince the deluge is an event ſo ſingular in its nature, that ſuppoſing it to have happened, the memory of it could never have been extinguiſhed amongſt the generality of nations which inhabit the earth; and more eſpecially, ſince learned men have abundantly proved that a tradition concerning a deluge has prevailed in every quarter of the globe; not only amongſt the Romans, Grecians, Egyptians, Babylonians, Perſians, Scythians, but amongſt the Iroquois, Mexicans, Braſilians, Peruvians, and other nations of America. Moreover, we are informed by one of the navigators to the Southern Hemiſphere, that the inhabitants of Otaheite being aſked concerning their origin, ſimply anſwered, that their ſupreme god a long time ago, being angry, dragged the earth through the ſea, and their iſland being broken off was preſerved. Now, if a tradition concerning a deluge has prevailed in almoſt every part of the globe, except in India, and, as ſome ſay, in China, may we not heſitate a little till we know more of thoſe countries, before we poſitively affirm, that they have no ſuch tradition? For it deſerves to be remarked, that what is ſaid in the preface to the code of Gentoo laws, relative to the want of a tradition concerning a deluge in the Gentoo Shaſters (or Scriptures) is contradicted by an author who lived in India, and wrote his account of the Banians about 150 years ago; for he expreſsly ſays, that he made his collections, by the help of interpreters, from the Shaſter, and he has the following words:—"As if the world needed cleanſing of its defilement and pollution, there came a flood, that covered all nations in the depths—and ſo concluded the firſt age of the world according to the tradition of the Banians." (Lord's Diſcovery of the Banian Religion, c. 6.) Sir William Jones, than whom there could not be a more competent judge, and one on whoſe teſtimony we may more ſecurely rely, affirms, "that a tradition concerning a deluge does certainly ſubſiſt in Hindooſtan," and that in the oldeſt mythological books there is ſuch an account of the deluge as ſufficiently correſponds with that of Moſes. (See Biſhop Watſon's Diſcourſe to the Clergy, &c. in his Sermons and Tracts, p. 220.) The learned prelate (p. 229.) has recorded a very curious paſſage, quoted in the "Flora Saturniſans" of Henckel (Paris ed. 1760) from the works of Rammazini, concerning the primitive ſtate of the earth, and the ſubſequent deluge, taken, as it is ſaid, from the moſt ancient an-

nals of Ethiopia. The account bears a great reſemblance to the hypotheſis of Dr. Burnet. It muſt be owned, however, that ſeveral of the deluges which tradition records, were merely topical inundations; and they ſhould be carefully diſtinguiſhed from that of Noah; though ancient and modern writers frequently confound them together. Moreover, natural, as well as civil, hiſtory bears a ſtrong teſtimony to Moſes's account of the deluge; and ſhews that it muſt have been univerſal, or nearly ſo, however difficult it may be for us, either to find ſources ſufficiently ample for ſo great a body of waters, or methods for removing them. The preſent external ſurface of the earth, its internal conſtitution, the arrangements of its various ſtrata, the remains of marine animals and petrified ſhells found at great diſtances from their original habitation, incorporated with the earth, or on eminences far elevated above the level of the ſea, and other circumſtances that preſent themſelves to the ſagacious naturaliſt in his ſurvey and examination of various parts of the terreſtrial globe, have been alleged as exiſting monuments of a deluge, and evidences of its univerſality. In vindication of the Moſaic account of the deluge, we might further allege the paucity of mankind, and the vaſt tracts of uninhabited land, which are mentioned in the hiſtories of the firſt ages, which ſhew that mankind were lately ſprung from a ſmall ſtock, and even ſuit the time aſſigned by Moſes for the flood. Moreover, the great number of ſmall kingdoms, and petty ſtates in the firſt ages, and the late riſe of the great empires of Egypt, Aſſyria, Babylon, &c. concur to the ſame purpoſe. We might add, the invention and progreſs of arts and ſciences, which alſo favour the Moſaic hiſtory of the antediluvians. As to the objections urged againſt the deluge from the ſize of the ark and the number of animals contained in it: ſee ARK.

The deluge has been, and remains, a ſubject of much enquiry and diſpute among naturaliſts, critics, &c. The points chiefly controverted may be reduced to three; firſt, its extent: *viz.* whether it were *general*, or *partial*; ſecondly, its natural cauſe; and, thirdly, its effects.

1. The immenſe quantity of water requiſite to furniſh an univerſal deluge, has occaſioned ſeveral authors to ſuſpect it only partial. An univerſal deluge, they think, had been unneceſſary, conſidering the end for which it was brought; *viz.* to extirpate the wicked inhabitants. The world was then but new, and the people not very many; the holy Scriptures making only eight generations from Adam to Noah. It was but a ſmall part of the earth that could be yet inhabited; the country about the Euphrates, which is ſuppoſed to have been the ſcene of the firſt antediluvian inhabitants, was ſufficient to bear them all. Now Providence, ſay they, which ever acts wiſely, and frugally, would never have diſproportioned the means to the end, ſo far as to overflow the whole globe, only to drown a little corner of it. They add, that, in the Scripture-language, the *whole earth* expreſſes no more than *all the inhabitants*; and on this principle advance, that an overflowing of the Euphrates and Tigris, with a vehement rain, &c. might anſwer all the phenomena of the deluge. Others pretend, that the deluge was confined to Judæa alone and the adjacent regions; or perhaps to the tract of land which lies between the four ſeas, the Perſian, Caſpian, Euxine, and Mediterranean; or, at moſt, that it reached no farther than the continent of Aſia, This, they ſay, would anſwer the purpoſe of deſtroying mankind, which was the primary object of this cataſtrophe. Indeed, Bedford, in his "Scripture Chronology," ſuppoſes that all mankind did not periſh in the deluge; and he has endeavoured to prove, from a peculiar expoſition of the curſes of Cain and Lamech, that the Africans and Indians are of their poſterity. But, if we advert to the language of ſcripture, we muſt conclude that the deluge was univerſal. God declared to Noah, Gen. vi. 17. that he was reſolved to deſtroy every thing that had breath under heaven, or had life on the earth, by a flood of waters; ſuch was the menace; ſuch the execution. The waters, Moſes aſſures us, covered the whole earth, buried all the mountains, and were no leſs than fifteen cubits above the higheſt of them: every thing periſhed therein; birds, beaſts, men, and all that had life, excepting Noah, and thoſe with him in the ark, Gen. vii. 19, &c. Can an univerſal deluge be more clearly expreſſed? If the deluge had only been partial, there had been no neceſſity to ſpend a hundred years in the building of an ark, and ſhutting up all the ſorts of animals therein, in order to re-ſtock the world: they had been eaſily and readily brought from thoſe parts of the world not overflowed, into thoſe that were: at leaſt, all the birds would never have been deſtroyed, as Moſes ſays they were, ſo long as they had wings to bear them to thoſe parts where the flood did not reach. If the waters had only overflowed the neighbourhood of the Euphrates and Tigris, they could not be 15 cubits above the higheſt mountains; they could not have riſen to that height, but they muſt ſpread themſelves, by the laws of gravity, over the reſt of the earth; unleſs, perhaps, they had been retained there by a miracle; and, in that caſe, Moſes, no doubt, would have related the miracle, as he did that of the waters of the Red ſea, and the river Jordan, which were ſuſtained in a heap, to give paſſage to the Iſraelites, Exod. xiv. 22. and Joſh. iii. 16. Add, that, in regions far remote from the Euphrates and Tigris, *viz.* in Italy, France, Switzerland, Germany, England, &c. there are frequently found in places many ſcores of leagues from any ſea, and even in the tops of high mountains, whole trees ſunk deep under ground; as alſo teeth and bones of animals, fiſhes entire, ſea-ſhells, ears of corn, &c. petrified; which many naturaliſts are agreed could never have come there but by the deluge, unleſs we ſuppoſe with others that theſe organic remains were of a prior race, and that the ſtrata of the earth (ſee STRATA) were formed previouſly to the deluge:—to which may be added the almoſt univerſal traditions of this great event in all countries of the globe.

2. The deluge allowed to be univerſal, the philoſophers are ſolicitous to find water to effect it.

Moſes brings it from two ſources: *the fountains of the great deep were broken up; and the windows of heaven were opened: and the rain was upon the earth* 40 *days and* 40 *nights.* Dr. Burnet, in his "Telluris Theoria Sacra," ſhews, that all the waters of the ocean were not near enough to cover the earth fifteen cubits above the tops of the higheſt mountains. According to his computation, no leſs than eight oceans were required. Suppoſing the ſea, therefore, drained quite dry, and all the clouds of the atmoſphere diſſolved into rain, we ſhould ſtill want much the greateſt part of the water of a deluge.

To get clear of this embarraſſment, many of our beſt naturaliſts, as Steno, Burnet, Woodward, Scheuchzer, &c. adopt Des Cartes' ſyſtem of the formation of the earth. That philoſopher will have the primitive world to have been perfectly round and equal, without mountains or vales; and accounts for its formation on mechanical principles, by ſuppoſing it at firſt in the condition of a thick turbid fluid, replete with diverſe heterogeneous matters which, ſubſiding by ſlow degrees, formed themſelves into different concentric ſtrata, or beds, by the laws of gravity; and thus, at length, left a dry ſolid earth. Dr. Burnet improves on this theory: he ſuppoſes the primitive earth to have been no more than an orbicular cruſt, ſmooth, regular, and uniform, without mountains, and without a ſea, inveſting the face of the abyſs,

or

or deep, which being heated by the ſun became dry and chinky, and by the rarefaction and expanſion of the encloſed vapours, clave, burſt, and fell down into the water, and ſo drowned its inhabitants.

The ſame theoriſt adds, that by this cataſtrophe, the globe of the earth was not only ſhaken, and broken in a thouſand places, but the violence of the ſhock it then underwent ſhifted its ſituation; ſo that the earth, which before was placed directly under the zodiac, or had the plane of the equator coincident with the plane of the ecliptic, ſo that the ſun in its diurnal motion would ſeem to move always in the equator, became henceforth oblique to the ſame. Whence aroſe the difference of ſeaſons, which did not belong to the antediluvian earth.

Thoſe maſſes of the earth which fell into the abyſs of waters, carried with them, according to this author, vaſt quantities of air, daſhed againſt each other, and accumulated and divided ſo irregularly, that great cavities filled with air, were left between them. The waters gradually opened paſſages into theſe cavities, and in proportion as the cavities were filled with water, the ſurface of the earth began to diſcover itſelf in the moſt elevated places; and, at laſt, the waters appeared nowhere but in thoſe extenſive vallies which contain the ocean. Thus our ocean is a part of the ancient abyſs, the reſt of it remains in the internal cavities, with which the ſea has ſtill a communication. Iſlands and ſea-rocks are the ſmall fragments; and continents are the large maſſes of the ancient cruſt. As both the rupture and fall of this cruſt were effected in a confuſed manner, it is not ſurpriſing that the ſurface of the preſent earth ſhould be full of mountains, gulfs, plains, and irregularities of every kind.

Dr. Burnet's hypotheſis is very elegantly recited, and has by ſome been called a romance: but it is utterly inconſiſtent with the ſacred text above cited, which expreſsly mentions mountains as the ſtandard of the height of the water; or with that other paſſage, Gen. viii. 22. where God, promiſing not to bring any more deluges, but that every thing ſhould be reſtored to its ancient ſtate, ſays, that *ſeed-time and harveſt, and cold and heat, and ſummer and winter, and day and night, ſhall ceaſe no more.*

It alſo contradicts the phyſical principles of nature, as Keill has ſhewn in his "Examination of Dr. Burnet's Theory of the Earth," p. 116, &c. ed. 2. This author, having ſhewn that the axis of the primitive earth was inclined to the plane of the ecliptic as it is at preſent, concludes, that it was ſubject to the ſame variety of ſeaſons and alterations of heat and cold as it is now; and, therefore, that all the arguments drawn from the great heat and ſtrong action of the ſun upon the antediluvian earth are of no avail, ſince there was then no greater heat of the ſun than there is at preſent. Beſides, judging from experience, the heat of the ſun does not penetrate far into the earth, and accordingly its beams could reach but a little way into the imaginary cruſt of the theoriſt; and within the bowels of the earth there is no ſenſible difference between the heat of the ſun when its action is ſtrongeſt, and when it is weakeſt. Since then the heat of the ſun does not penetrate the earth ſo as to be ſenſible for the ſmall ſpace through which we are able to dig, how can we imagine it poſſible that it ſhould ever reach the abyſs, through the whole exterior cruſt of the earth, ſo as to be able to heat the water and raiſe it into vapour? But even allowing that the heat of the ſun had reached the abyſs, and had raiſed the vapours ſo that the cruſt of the earth fell down and was broken into pieces, we cannot infer that the conſequence would be an univerſal deluge, or indeed any deluge at all. Admitting the author's own principles, all the water contained in the abyſs was long before the time of the deluge drawn out of the abyſs, and placed on the ſurface of the earth; and in this caſe how can he conſiſtently explain an univerſal deluge by the fall of the outward cruſt of the earth upon the abyſs? This fall would have been ſo far from being the cauſe of a deluge, that it would have proved the moſt effectual method of reſcuing the earth from a deluge of waters which were then upon it. For all the water which was in the abyſs, being drawn up on the ſurface of the land, and the earth being of a ſpheroidical and oval ſhape, without hills and mountains, upper and lower grounds, but exactly of the ſame figure which its gravity and centrifugal force formed it into, when it was fluid; the great maſs of water which was then upon the earth muſt have ſettled itſelf alſo in the ſame figure, as it had no banks to retain it within its channel, or mountains to keep it within bounds; and the true effect of the fall of the cruſt muſt have been to have diſcovered the land, and the waters would have run from the ſurface of the earth into the abyſs, and there would have formed a ſea, and made that land appear which before was covered with waters. But ſuppoſing that all the water, which is now in the ocean, was in the abyſs at the time of the deluge, and that the cruſt of the earth was broken and had fallen down on the ſurface of the abyſs, yet how could this fall produce an univerſal deluge, and make the waters ſwell above the tops of the higheſt mountains? For Dr. Burnet himſelf calculates, that it would require eight oceans of waters to cover the face of the whole earth, and raiſe the waters to a height ſufficient for drowning the world. As there is but one ocean of water in the abyſs, the fall of the cruſt could only produce a partial and topical deluge. Beſides, if the abyſs contained water ſufficient for covering the face of the whole earth at once, yet it is not poſſible to conceive how ſuch a flood of waters that was raiſed by the fall of the cruſt could laſt for ſo long a time, as the Scriptures inform us Noah's flood did, which was 150 days without abating on the face of the earth.

Other authors, ſuppoſing a ſufficient fund of water in the abyſs, or ſea, are only concerned for an expedient to bring it forth: accordingly, ſome, as Mr. Ray, &c. have recourſe to a ſhifting of the earth's centre, which, drawing after it the water out of its channel, overwhelmed the ſeveral parts of the earth ſucceſſively. But this could only occaſion a partial deluge in that part of the globe towards which the centre of gravity was tranſlated: nor can the poſſibility of ſuch a tranſlation be allowed, ſince the centre of gravity is the neceſſary reſult of the materials compoſing our globe, and not alterable whilſt the parts remained in the ſame poſition.

Dr. Hook's opinion of the compreſſion of a ſhell of earth into a prolate ſpheroid, thereby preſſing out the water of an abyſs under the earth, may very well account for the waters overflowing two oppoſite zones of the globe; but the middle zone being by much the greater part of the earth's ſurface, muſt by this means be raiſed higher from the centre, and conſequently ariſe more out of the water than before.

In Hook's "Diſcourſe of Earthquakes," written about the year 1688, there is mention made of the bottom of the ſea having been raiſed by ſubterraneous fires; and he accounts for the ſhells which are found on mountains from that principle, and thinks it not improbable, that earthquakes were inſtrumental in occaſioning the deluge. "The Alps and divers other high mountains, on whoſe tops are found ſuch numbers, and ſuch varieties of ſea-ſhells, may have been heretofore raiſed up from the bottom of the ſea—it is not improbable but in the flood of Noah, the Omnipotent might

make uſe of this means (earthquakes) to produce that great effect."

Dr. Halley aſcribes the deluge to the ſhock of a comet, or ſome other ſuch tranſient body, whereby the polar and diurnal rotation of the globe would be inſtantly changed. The great agitation that muſt have been occaſioned by it in the ſea, he obſerves, would be ſufficient to account for all thoſe ſtrange appearances of heaping vaſt quantities of earth and high cliffs upon beds of ſhells, which were once the bottom of the ſea, and raiſing up mountains where none were before. Such a ſhock as this, impelling the ſolid parts, would occaſion the waters, and all fluid ſubſtances that were unconfined, as the ſea is, to run violently with an impetus towards that part of the globe where the blow was received, and that with force ſufficient to take with it the very bottom of the ocean, and remove it to the land. In this caſe, it is much more difficult to ſay, how Noah and his family could be preſerved, than how all other creatures were deſtroyed: ſuch a ſhock would change the length of the day and year, by altering the axis of the globe, according to the obliquity of the incidence of the ſtroke. It is objected to this ſyſtem, that ſuch a ſhock muſt have brought on the deluge inſtantaneouſly, and not gradually, as it is ſaid to have happened. Phil. Tranſ. N° 383. p. 120, or abr. vol. vii. p. 1, &c.

The inquiſitive Mr. Whiſton, in his "New Theory of the Earth," has a very ingenious hypotheſis, ſimilar to that ſuggeſted by Dr. Halley, with reſpect to the primary cauſe of the deluge, but much more largely applied and explained. He ſhews, from ſeveral remarkable coincidences, that a comet, deſcending in the plane of the ecliptic towards its perihelion, paſſed juſt before the earth on the firſt day of the deluge; the conſequences whereof would be, firſt, that this comet, when it came below the moon, would raiſe a prodigious, vaſt, and ſtrong tide, both in the ſmall ſeas, which, according to his hypotheſis, were in the antediluvian earth, for he allows no great ocean there, as in ours; and alſo in the abyſs, which was under the upper cruſt of the earth; and that this tide would riſe, and increaſe all the time of the approach of the comet towards the earth; and would be at its greateſt height when the comet was at its leaſt diſtance from it. By the force of this tide, and alſo by the attraction of the comet, he judges, that the abyſs muſt put on an elliptic or rather an exactly oval figure, whoſe ſurface being conſiderably larger than the former ſpherical one, the outward cruſt of the earth, incumbent on the abyſs, muſt accommodate itſelf to that figure, which it could not do while it remained ſolid and conjoined together. He concludes, therefore, that it muſt of neceſſity be extended, and at laſt broke, by the violence of the ſaid tides, and attraction; and have innumerable fiſſures made quite through it; out of which, the included water iſſuing, was a great means of the deluge; this anſwering to what Moſes ſpeaks of the *fountains of the great deep being broken open.* Again, the ſame comet, he ſhews, in its deſcent towards the ſun, muſt have paſſed ſo cloſe by the body of the earth as to involve it in its atmoſphere, and tail, for a conſiderable time; and of conſequence, it muſt have left a vaſt quantity of its vapours, both expanded and condenſed, on its ſurface; a great part of which, being rarefied by the ſolar heat, would be drawn up again into the atmoſphere, and afterwards deſcend in violent rains upon the earth: and this he takes to be what Moſes intimates *by the windows of heaven being opened;* and particularly by the *forty days rain.* For as to the following rain, which, with this, made the whole time of raining an hundred and fifty days, Mr. Whiſton attributes it to the earth coming a ſecond time within the atmoſphere of the comet, as the comet was on its return from the ſun. From the comet's atmoſphere and tail he derives one-half of the water, which ſerved for the deluge; the other half, he ſuppoſes, was deduced from the ſubterraneous abyſs, the fluid of which, he ſays, was forced upon the ſurface of the earth by the prodigious preſſure of the incumbent water that was derived from the comet's atmoſphere and tail, which, he ſuppoſes, would preſs downwards with a mighty force, and endeavour to ſink the outward cruſt of the earth into the abyſs; by the preſſure of which vaſt quantities of the ſubterraneous fluid would be forced and raiſed upon the ſurface of the earth, through the cracks and fiſſures that were made in the cruſt by the violence of the tide in the abyſs. By this method, Mr. Whiſton ſuppoſes that water enough would be obtained on the ſurface to cover the face of the whole earth to the perpendicular height of three miles, that is, above the tops of the higheſt mountains. But he further ſuppoſes, that neither that water which was derived from the comet, nor that which was forced up from the bowels of the earth, was pure elementary water, but rather a thick and muddy fluid, which, he ſays, being heavier than water, ſunk to the bottom and covered the earth to the depth of 166 feet. Laſtly, to remove this vaſt orb of waters again, he ſuppoſes a mighty wind to have ariſen, which dried up ſome, and forced the reſt into the abyſs again through the clefts by which it came up: only a good quantity remained in the alveus of the great ocean, now firſt made, and in leſſer ſeas, lakes, &c.

To the credit of this theory, it muſt be obſerved, that it was at firſt only propoſed hypothetically: that is, the author only ſuppoſed ſuch a comet, merely as it would account well, and philoſophically, for the phenomena of the deluge; without any aſſurance, that there really was any comet ſo near the earth at that time; and the hypotheſis pleaſed even under ſuch circumſtances: but, upon further conſideration, he has ſince, he thinks, proved, that there actually was a comet near the earth at that time, or 28th November, in the 2365th year of the Julian period, or the 2349th year before Chriſt, to which time he aſſigns the beginning of the deluge, *viz.* the ſame great comet which appeared again in 1680. The author no longer, therefore, looks upon it as an hypotheſis, but has republiſhed it in a particular tract, intitled, "The Cauſe of the Deluge demonſtrated."

Mr. Keill, in his "Remarks on Mr. Whiſton's Theory," acknowledges that it is much more philoſophical than many others, and that he has rendered probable the approach of a comet at the preciſe time of the deluge. He objects, however, to his explications of ſeveral phenomena of the deluge, as not agreeable to the laws of mechanics and philoſophy; although it is certain, that a comet, when it paſſed by the earth, would raiſe a very ſtrong tide in the ſeas that were then on the ſurface; yet it is very far from being evident, that ſuch an effect would be produced in the abyſs, which, he ſuppoſes, to be a denſe and heavy fluid encompaſſed on all ſides with a thick and ſolid cruſt of earth lying cloſely upon it. Hence, if there was no tide in the abyſs, it could make no cracks and fiſſures in the earth. Mr. Whiſton, in explaining the great rains, which fell on the earth during the time of the deluge, aſſumes a propoſition ſcarcely capable of proof; *viz.* that after the earth was involved in the comet's atmoſphere and tail, and had acquired a prodigious quantity of condenſed and expanded vapours that fell on its ſurface, a great part of them being much rarefied would be drawn up again into the air, and afterwards deſcend in violent rains. If we conſider the incredible velocity with which thoſe vapours deſcended, being at the rate of 868 miles in a minute, and the great reſiſtance they met with

with in their deſcent through the air, and the force with which they fell on the ground; we muſt admit their condenſation and converſion into water, by ſuch a reſiſtance and fall. Hence, it is evident, that all ſuch vapours as deſcended from the comet muſt have been condenſed into water long before they ever touched the earth. Since then, they deſcended on the earth in the form of water, and the heat of the ſun was not ſufficient to raiſe them up again immediately, it is plain they could never riſe up ſo as to produce the 40 days rain mentioned in Scripture. Mr. Keill alſo objects to Mr. Whiſton's account of the effect of the preſſure of the waters, that had deſcended from the comet, on the cruſt of the earth, ſo as to occaſion the aſcent of the waters of the abyſs through the cracks and fiſſures on the ſurface of the earth. He thinks it is demonſtratively evident, that by no ſort of preſſure of the incumbent fluid the abyſs could be forced upwards to ſpread itſelf on the ſurface of the earth. Mr. Keill further examines Mr. Whiſton's method of drawing from the earth the waters neceſſary for the deluge, which he attributes partly to a drying wind, and partly to the deſcent of the waters through the fiſſures of the earth. But he previouſly eſtimates the quantity of waters that would be neceſſary to cover the whole earth above the tops of the higheſt mountains. Dr. Burnet, as we have already mentioned, ſtates it to be about eight oceans of water, ſuppoſing the ſurface of the ſea to be equal to the land, and to be every where, at an average, a quarter of a mile deep. Keill thinks it to be about three times as much. In order to aſcertain this point, he aſſumes the perpendicular height of the higheſt mountain above the level of the ocean to be above three miles. Upon this ſuppoſition, the waters muſt be raiſed more than three miles in perpendicular height that they may be as high as the tops of the hills. It is eaſy to calculate how much water would be neceſſary to raiſe the ſurface of the ſea to ſuch a height. The ocean being by hypotheſis a quarter of a mile deep, there muſt not be leſs than twelve oceans of water lying on the ſurface of the ſea, that it may be of the ſame height with the water which covered the land. Mr. Keill, by purſuing his calculation, on the ſuppoſition that the ſurface of the earth is beſet with mountains, each of which is three miles perpendicularly high, eſtimates the whole quantity of water that would be neceſſary for an univerſal deluge at 22 oceans, beſides the waters that compoſe the preſent ocean, or in the whole 23 oceans. But if the height of the mountains be greater, more water will be required to anſwer the purpoſe. (See the ſequel of this article.) Although ſuch a quantity of water may be ſuppoſed to be derived from the atmoſphere of a comet, yet it will not be eaſy to contrive a method for removing it again from the earth; that which Mr. Whiſton propoſes by evaporation and by deſcent into the abyſs, being very inſufficient for the purpoſe.

3. But the great difficulty ſtill remains. The orderly ſtrata, or layers of the earth, with the exuviæ, or remains of fiſhes, as their teeth, bones, ſhells, &c. both marine, and fluviatile, found in the bodies even of the moſt ſolid ſtrata, and in flints, marbles, &c. are not yet accounted for. Thoſe who adhere to Des Cartes' ſyſtem, as Steno, &c. take the finding of the parts of terreſtrial, and aquatic animals, branches of trees, leaves, &c. in the beds, or ſtrata of ſtone, to be a direct proof of the primitive fluidity of the earth. But then they are obliged to have recourſe to a ſecond formation of ſtrata, much later than the firſt; becauſe, at the time of the firſt there was neither plant nor animal in being. Steno, therefore, maintains ſecond formations, occaſioned at different times by extraordinary inundations, earthquakes, volcanoes, &c. But Burnet, Woodward, Scheuchzer, &c. chooſe rather to attribute a ſecond general formation to the deluge; without excluding, however, the particular ones of Steno. But the great objection againſt this ſyſtem of fluidity, is mountains; for the whole globe being liquid, whence ſhould ſuch inequalities ariſe? Mr. Scheuchzer, rather than part with a ſyſtem which ſeems ſo promiſing, gives into the opinion of thoſe who hold, that, after the deluge, God, to remit the waters into their ſubterranean reſervoirs, broke and diſplaced, with his own almighty hand, a great number of ſtrata, that were before horizontal, and raiſed them above the ſurface of the earth, which was originally land; whence it is, that the ſtrata in mountains, though concentrical, are never horizontal. Hiſt. de l'Acad. 1708. p. 32. Piſcium Querelæ, &c. and Phyſica Sacra.

Dr. Woodward, taking the ſeveral ſtrata for the ſediments of a deluge, and conſidering the circumſtances of thoſe fiſhes, ſhells, and other exuviæ, found in them, draws ſeveral inferences, which very much illuſtrate the effects of the deluge. As, firſt, that theſe marine bodies, and other ſpoils of ſalt-water fiſhes, were borne forth out of the ſea, by the univerſal deluge; and, on the return of the water back again, were left behind upon the land. Secondly, that while the flood covered the globe, all the ſolid matters, as ſtones, metals, minerals, and foſſils, were totally diſſolved, and the cohéion of their corpuſcles deſtroyed; and that their corpuſcles, with thoſe of the leſs ſolid bodies, as earth, fleſh of animals, and vegetables, were ſuſtained promiſcuouſly in the water, and made one common maſs. Thirdly, that all the maſs, thus ſuſtained, was at length precipitated to the bottom; and that, according to the laws of gravity, the heavieſt ſettled firſt, and the reſt in order. And that the matters, thus ſubſiding, conſtituted the ſeveral ſtrata of ſtone, earth, coal, &c. Fourthly, that theſe ſtrata were originally all parallel, even, and regular, and rendered the ſurface of the earth perfectly ſpherical; and that the whole maſs of water lay upon them, and conſtituted a fluid ſphere encompaſſing the globe. Fifthly, that after ſome time, by the force of an agent ſeated within the earth, theſe ſtrata were broken on all ſides of the globe, and their ſituation varied; being elevated in ſome places, and depreſſed in others; whence mountains, vallies, grottos, &c. with the channel of the ſea, iſlands, &c. In one word, the whole terraqueous globe was put, by this diſruption, and diſlocation of the ſtrata, into the condition we now behold it in. Sixthly, that upon the diſruption of the ſtrata, and the depreſſion of ſome and elevation of other parts, which happened towards the end of the deluge, the maſs of water fell back again into the depreſſed and loweſt parts of the earth, into lakes, and other cavities, and the channel of the ocean, and through the fiſſures, whereby this communicates with the abyſs, which it filled till it came to an equilibrium with the ocean. Nat. Hiſt. of Earth, p. 1. and 2.

To this ſyſtem it has been objected, that it is abſurd to ſuppoſe, that, before the deluge, there were no mountains, ſince we are expreſsly told, that the waters roſe 15 cubits above the tops of the higheſt mountains: on the other hand, it is not ſaid that the waters deſtroyed or diſſolved the mountains. On the contrary, the mountains remained firm in their original ſituation, and the ark reſted upon that which was firſt deſerted by the waters. Beſides, it cannot be reaſonably imagined, that, during the ſhort time of the deluge, the waters could diſſolve the mountains, and the whole fabric of the earth. Can we ſuppoſe, that, in the

ſpace of 40 days, the hardeſt rocks and minerals were diſſolved by ſimple water, and yet that ſhells, bones, and other productions of the ſea, were able to reſiſt a menſtruum to which the moſt ſolid materials had yielded?

Dr. Woodward aſſerts, that the materials of the different ſtrata are arranged according to their ſpecific gravities. To this it has been objected, that we every day ſee ſolid rocks placed above clay, ſand, pit-coal, bitumen, and other comparatively light bodies. If, indeed, it were uniformly found, through the whole earth, that the upper ſtratum was bitumen, followed ſucceſſively by ſtrata of chalk, marl, clay, ſand, ſtone, marble, and metals, it would, in that caſe, be probable, that all theſe materials had been precipitated at once; and this Mr. Woodward confidently affirms. Whereas, the moſt ſuperficial obſerver need only open his eyes to convince himſelf, that heavy ſtrata are often found above light ones; and, conſequently, that theſe ſediments could not be depoſited at the ſame time, but muſt have been tranſported and depoſited, as M. Buffon ſays, by the ocean at ſucceſſive periods. See STRATA.

M. de la Pryme has advanced another ſyſtem for ſolving the phenomena of petrified exuviæ.

The antediluvian world, according to this author, had an external ſea, as well as land, with mountains, rivers, &c. and the deluge was effected by breaking the ſubterraneous caverns, and pillars thereof, with dreadful earthquakes, and cauſing the ſame to be for the moſt part, if not wholly, abſorbed and ſwallowed up, and covered by the ſeas that we now have. Laſtly, this earth of ours aroſe out of the bottom of the antediluvian ſea, and in its room; juſt as many iſlands are ſwallowed down, and others thruſt up in their ſtead.

This ſyſtem, it has been ſaid, is very agreeable to Scripture, and eaſily ſolves the great difficulties that clog all the other ſyſtems. It is no longer a wonder, that ſhells, and ſhell-fiſh, and the bones of fiſhes, and four-footed creatures, with fruits, &c. ſhould be found in beds and quarries, in mountains and vallies, and the very bowels of the earth: for here they bred in the antediluvian ſea; thither they were elevated with the hills and mountains, in the time of the deluge; and there they fell into, were abſorbed, and buried in chaſms, and holes and clefts, that would neceſſarily happen in the extruſion of the earth. Phil. Tranſ. N° 266.

Mr. King has more lately adopted an hypotheſis reſembling this laſt. He aſcribes the deluge to ſubterraneous fires found within the bowels of the earth, which, at the appointed time, burſt forth with great violence under the ſea, and raiſed up the bottom of the ocean, ſo as to pour out the waters over the face of what was before dry land, which by that means became the ſea, and has ſince continued, and that which was before the bottom of the ſea became dry land. An earthquake thus occaſioned will account, he ſuppoſes, for the acceſs of the deluge and the confuſed diſpoſition of marine productions in the poſtdiluvian earth. Phil. Tranſ. vol. lvii. p. 44, &c.

Mr. King's hypotheſis has been much enlarged by M. de Luc. According to this hypotheſis the ancient continents muſt have exiſted in thoſe tracts now covered by the Atlantic and Pacific oceans. It has been objected to this theory, that it is inconſiſtent with the Moſaic account of the deluge, which account theſe philoſophers, however, admit. Moſes aſcribes the deluge to two principal cauſes, a rain of 40 days and the eruption of the waters of the great abyſs. Now to what purpoſe, it has been queried, a rain of 40 days to overwhelm a continent, that was to be immerſed under a whole ocean? He informs us that the waters increaſed on the continents for a certain number of days, reſted thereon another period of days, and then returned. Do not theſe expreſſions imply a permanent ground on which they increaſed and reſted, and from which they afterwards retreated? As the retreat followed the advance, is it not clear that they retreated from the ſame ſpace on which they had before advanced and reſted?

M. de Luc replies, that in the 13th verſe of the ſixth chapter of Geneſis it is ſaid the earth ſhould be deſtroyed, and that Michaelis ſo tranſlates it. But from the obſervations already made, it is plain that Moſes did not underſtand ſuch a deſtruction as ſhould cauſe it to diſappear totally and for ever: he tells us that the waters ſtood 15 cubits over the higheſt mountains; and as he has no where mentioned the antediluvian mountains, but has taken notice of the poſtdiluvian, it is plain that his narrative relates to theſe, and theſe, he ſays, were at the time of the deluge covered with water, and uncovered when the waters diminiſhed: he never diſtinguiſhed the poſtdiluvian from the antediluvian, and therefore muſt have conſidered them as the ſame. Beſides, Noah himſelf did not believe that the ancient continents were deſtroyed, for he took the appearance of an olive-branch to be a ſign of the diminution of the flood; that he certainly believed to have grown on the ancient continent, and could not expect it to have ſhot up from the bottom of the ſea. M. de Luc indeed ſays, that this olive grew on an antediluvian iſland, and that theſe iſlands being part of the antediluvian ocean, were not flooded: but it is plain from the hiſtory, that Noah thought otherwiſe, or elſe he could not have inferred that the appearance of the olive was a ſign of the abatement of the waters. But where is it mentioned, or what renders it neceſſary to conclude that iſlands exiſted before the flood? If iſlands did exiſt, and were to eſcape the flood, ſo might their inhabitants alſo, in direct contradiction to the ſacred hiſtory. Would it not have been much more convenient for Noah, his family and animals, to have taken refuge in one of them, than to have remained pent up in the ark? Moreover, Moſes informs us, that at the ceſſation of the flood the fountains of the deep were ſtopped or ſhut up; therefore, in his apprehenſion, inſtead of the ancient continents ſinking into the deep, the waters of the abyſs flowed from their ſources upon thoſe continents, and again returned. See Kirwan's Remarks, *ubi infra*.

Mr. Whitehurſt in his "Inquiry into the Original State and Formation of the Earth," &c. (4to. 1786) has attempted to account for the univerſal deluge in the following manner. "It is a truth," he ſays, "univerſally known that all bodies expand with heat: and that the force or power of that law is unlimited; now, as ſubterraneous fire gradually increaſed, ſo in like manner its expanſive force increaſed, until it became equal to the incumbent weight. Gravity and expanſion being equally balanced, and the latter continuing to increaſe, every day, more and more, became ſuperior to the incumbent weight, and diſtended the ſtrata as a bladder forcibly blown. Now, if fire thus generated was ſurrounded by a ſhell or cruſt, of equal thickneſs, and of equal denſity, the incumbent weight muſt have been equal: on the contrary, if the ſurrounding ſhell, or cruſt, was unequally denſe, the incumbent weight muſt have been unequal. But ſince the primitive iſlands were protuberances gradually aſcending from the deep, the incumbent weight muſt have been unequal; for as the ſpecific gravity of ſtone, ſand, or mud, is ſuperior to that of water, we may thence conclude that the incumbent weight of the former muſt have been greater than that of the latter. Now the incumbent weight of the iſlands being greater than that of the ocean, the bottom of the ſea would conſequently aſcend by the expanſive force below, ſooner than the iſlands. The bottom of the ſea being thus elevated, the

CONFIRMATION.

CONFIRMATION, in *Law*, denotes the conveyance of an eſtate, or right *in eſſe*, which a perſon hath in or to lands, &c. from one man to another that hath the poſſeſſion or ſome eſtate in it, whereby a voidable eſtate is made ſure and unavoidable, or a particular eſtate is increaſed, or poſſeſſion made perfect: and it is particularly uſed for the ſtrengthening or homologating an eſtate of one already in poſſeſſion of it by a voidable title. Thus, if a biſhop grant his chancellorſhip by patent, for term of the patentee's life; this is no void grant: yet it is avoidable by the biſhop's death, except it be ſtrengthened alſo by the confirmation of the dean and chapter. 1 Inſt. 295.

CONFIRMATION is alſo defined to be the approbation or aſſent to an eſtate already created: which as far as it is in the power of the confirmer, makes it good and valid; ſo that the confirmation doth not regularly *create an eſtate*, yet ſuch words may be blended in the confirmation as may create and enlarge an eſtate; but this takes place by the force of ſuch words as are foreign to the buſineſs of confirmation, and by their own force and power, tend to create the eſtate. Gilb. Ten. 75. A confirmation, ſays judge Blackſtone, is of a nature nearly allied to a releaſe; and the words of making it are theſe "have given, granted, ratified, approved, and confirmed." (Litt. § 515. 531.) An inſtance of the firſt branch of the above definition is, if tenant for life leaſeth for 40 years, and dieth during that time; here the leaſe for years is voidable by him in reverſion; yet, if he hath confirmed the eſtate of the leſſee for years, before the death of the tenant for life, it is no longer voidable but ſure. (Litt. § 516.) The latter branch, or that which tends to the increaſe of a particular eſtate, is the ſame in all reſpects with that ſpecies of releaſe, which operates by way of enlargement.

Madox ſays, that moſt ancient confirmations, made after the conqueſt, often run like feoffments; and are diſtinguiſhable from them, chiefly by ſome words inſerting a former feoffment or grant. In former times, when feoffees were frequently diſſeiſed of their lands upon ſome ſuggeſtion or other, charters of confirmation ſeem to have been in great requeſt. Poſſeſſors of lands, &c. ſeemed not to have thought themſelves ſecure againſt the king, or the great lords who were their feoffors, or in whoſe lands their fees lay, unleſs they had repeated confirmations from them, their heirs or ſucceſſors. And theſe ancient confirmations ſeem to have been ſometimes made, either by precept or writ from the king, or other lords, to put the feoffees, or their heirs or ſucceſſors into ſeiſin, after they had been diſſeiſed, or to keep them in their ſeiſin undiſturbed, or elſe by charter of expreſs confirmation. Confirmation is "*perficiens*, *creſcens*, or *diminuens*:" *perficiens*, as if feoffee upon condition make a feoffment, and the feoffor confirm the eſtate of the ſecond feoffee;—*creſcens*, which always enlarges the eſtate of a tenant; as tenant for years to hold for life, &c.;—and *diminuens*, as when the lord of whom the land is holden, confirms the eſtate of his tenant, to hold by a leſs rent. 9 Rep. 142.

The lord may diminiſh the ſervices of his tenant by confirmation; but not reſerve new ſervices, ſo long as the former eſtate in the tenancy continues; and therefore if he confirm to the tenant, to yield him a hawk, &c. yearly, it is void. (Litt. § 539. 1 Co. Inſt. 296.) Leaſes for years may be confirmed for part of the term, or for part of the land, &c.; but an eſtate of freehold, being entire, cannot be confirmed for part of the eſtate. (5 Rep. 81.) There may be a confirmation implied by law, as well as expreſs by deed; where the law by conſtruction confirms a grant made to another purpoſe: and a confirmation may enlarge an eſtate, from an eſtate held at will to term of years, or a greater eſtate, from an eſtate for years to an eſtate for life; from ane ſtate for life, to an eſtate in tail, or in fee; and from an eſtate in tail to an eſtate in fee-ſimple. (1 Inſt. 305. 9 Rep. 142. Dyer. 263.) But if the confirmation be made to leſſee for life or years, of his term or eſtate, and not of the land, this doth not increaſe the eſtate; though if the leſſee confirm the land, to have and to hold to the leſſee and his heirs, this will enlarge the eſtate, and ſo of the reſt. Co. Litt. 299. Plowd. 40.

In every good confirmation, there may be a precedent rightful or wrongful eſtate in him to whom made, or he muſt have the poſſeſſion of the thing as a foundation on which the confirmation is to be eſtabliſhed; the confirmer muſt have ſuch an eſtate and property in the land, that he may thereby be enabled to confirm the eſtate of the confirmee; the precedent eſtate muſt continue till the confirmation come, ſo that the eſtate to be increaſed comes into it; and it is required that both theſe eſtates be lawful. Co. Litt. 296. 1 Rep. 146. Dyer. 109. 5 Rep. 15. If tenant for life make a leaſe for years to one perſon, and afterwards leaſe the land to another perſon for years; and he in reverſion confirms the laſt leaſe, and after that the firſt leaſe, this is not good; the ſecond leſſee hath an intereſt before by the confirmation of him in reverſion. But in a like caſe, confirmation of the firſt leaſe, after the ſecond was confirmed, has been held good; for the leaſe takes no intereſt by the confirmation, but only to make it durable and effectual. Moor. c. 180. 1 Inſt. 296. Plowd. 10. If a diſſeiſee confirm the land to the diſſeiſor but for one hour, one week, a year, or for life, &c. it is a good confirmation of the eſtate for ever; and if he confirm the eſtate of the diſſeiſor without any word of heirs, he hath a fee-ſimple; and if a diſſeiſee make a gift in tail, and the diſſeiſee doth confirm the eſtate of the donee, it ſhall enure to the whole eſtate. (Co. Litt. 291, 297, 299.) But where the eſtate is divided it is otherwiſe; and if there be an eſtate for life, the remainder over, there the confirmation may be of either of the eſtates; and if the leſſee of a diſſeiſor of a leaſe for 20 years, make a leaſe for 10 years, the diſſeiſee may confirm to one of them and not to the other. (1 Cro. 472. 5 Rep. 81.) The tenant in tail of land hath a reverſion in fee expectant; in this caſe, the confirmation of the eſtate tail will not extend to the reverſion: &c. (Co. Litt. 297, 298.) If leſſee for years, without impeachment for waſte, accept a confirmation of his eſtate for life, he hath by this loſt the privilege annexed to his eſtate for years. (8 Rep. 76.) Acceptance of rent in ſome caſes makes a confirmation of a leaſe. (2 Danv. 128, 129.) What a perſon may defeat by his entry, he may make good by his confirmation. (Co. Litt. 300.) But none can confirm, unleſs he hath a right at the time of the grant: he who hath but a right in reverſion cannot enlarge the eſtate of a leſſee. (2 Danv. 140, 141.) As confirmation is to bind the right of him who makes it, but not alter the nature of the eſtate to him to whom made, it ſhall not diſcharge a condition. (Poph. 51. 1 Rep. 147.) A confirmation will take away a condition annexed by law; and by confirmation, a condition after broken in a deed of feoffment is extinguiſhed. (1 Co. Rep. 146.) Confirmations may make a defeaſible eſtate good; but cannot work upon an eſtate that is void in law. (Co. Litt. 295.)

A confirmation of letters patent, which are void as they are againſt law, is a void confirmation. (1 Lil. Abr. 295.)

Grants and leaſes of biſhops, not warranted by the ſtat. 32 Hen. VIII. c. 28. muſt be confirmed by dean and chapter;

the poſſibility and reality of the deluge, proceeds in his endeavours to trace its origin, progreſs, and ſtill permanent conſequences. That it originated in and proceeded from the great ſouthern ocean below the equator, and thence ruſhed on the northern hemiſphere, he takes to be a natural inference from the facts which he has adduced. Theſe facts are as follow: 1. The ſouthern ocean is the greateſt collection of waters on the face of the globe. 2. In the northern latitudes beyond 45° and 55° we find the animal ſpoils of the ſouthern countries, and the marine exuviæ of the ſouthern ſeas; but in the ſouthern latitudes we find no remains of animals, vegetables, or ſhells belonging to the northern ſeas, but thoſe only that belong to the neighbouring ſeas. 3. The traces of a violent ſhock or impreſſion from the ſouth are as yet perceptible in many countries. 4. The very ſhape of the continents, which are all ſharpened towards the ſouth, where they are waſhed by the Southern ocean, indicate that ſo forcible an impreſſion was made upon them as nothing but the mountains could reſiſt; ſuch are the Cape of Good Hope, Cape Comorin, the ſouthern extremity of New Holland, and that of Patagonia. To theſe geological proofs, Mr. Kirwan adds the tradition of the orthodox Hindoos, that the globe was divided into two hemiſpheres, and that the ſouthern was the habitation of dæmons, who made war upon the gods. (Aſiatic Reſearches, vol. iii.) This war is commonly thought to be an allegorical deſcription of the flood; and hence the olive-branch, denoting a diminution of the flood, became a ſymbol of peace. Did not Noah, our author adds, reſide on the borders of the ſouthern ocean, otherwiſe he could not ſee that the great abyſs was opened? And did not an inundation from the ſouth-eaſt drive the ark north-weſt to the mountains of Armenia? Theſe conjectures are at leaſt conſiſtent with the moſt probable notions of the primitive habitation of man, which Mr. Kirwan takes to be near the ſources of the Ganges (as Joſephus expreſsly mentions), the Bourampooter, and the Indus, from which, as the temperature grew colder, mankind deſcended to the plains of India.

This unparalleled revolution, as Moſes informs us, was introduced by a continual rain of 40 days; by which, our author conceives, the ſurface of the earth muſt have been looſened to a conſiderable depth, and the effects of which were in many inſtances deſtructive. This looſening and opening of the earth occurred in many places where the marine inundation ſtagnated; and thus ſhells and other marine exuviæ were introduced into the ſoil, which rendered it more fertile. This rain alſo diluted the ſalt-water, and ſerved to prevent its pernicious effects both to the ſoil and the freſh-water fiſh. The deſtruction of animals contributed to the ſame purpoſe, and might, in many inſtances, be neceſſary to fertilize a ſoil produced by the decompoſition of primary mountains: from the animals thus deſtroyed the phoſphoric acid found in many ores may have originated. But the completion of this cataſtrophe was undoubtedly effected, as Moſes ſtates, by the invaſion of the waters of the great abyſs; moſt probably, as our author apprehends, that immenſe tract of ocean ſtretching from the Philippine iſlands, or rather from the Indian continent, on the one ſide, to Terra Firma on the other, and thence to the ſouthern pole, and again from Buenos Ayres to New Holland, and thence to the pole. Tracing its courſe on the eaſtern part of the globe, we ſhall ſee it impelled northwards with reſiſtleſs impetuoſity againſt the continent which at that time probably united Aſia and America. This appears to have been torn up and ſwept away (except the iſlands that ſtill remain), as far north as latitude 40°: its farther progreſs appears to have been ſomewhat checked by the lofty mountains of China and Tartary, and thoſe on the oppoſite American coaſt; here it began to dilate itſelf over the collateral countries; the part checked by the Tartarian mountains forming, by ſweeping away the ſoil, the deſert of Coby, while the interior or middle torrent paſſed forward to the pole; but the interior ſurge being ſtill more reſtricted by the contiguous, numerous, and elevated mountains of eaſtern Siberia and America, muſt at laſt have ariſen to a height and preſſure which overbore all reſiſtance, daſhing to pieces the heads of theſe mountains, as Patrin and Steller remark, and bearing over them the vegetable and animal ſpoils of the more ſouthern ravaged or torn-up continents, to the far-extended and inclined plains of weſtern Siberia, where its free expanſion allowed it to depoſite them. Hence the origin of the bones and tuſks of elephants, and rhinoceri found in the plains, or inconſiderable ſandy or marly eminences in the north-weſtern parts of Siberia, as Mr. Pallas rightly judges. If now we return to the ſouth, and contemplate the effects of this overwhelming invaſion on the more ſouthern regions of India and Arabia, we ſhall, where the coaſts were undefended by mountains, diſcover it excavating the gulfs of Nanquin, Tonquin, and Siam, the vaſt bay of Bengal, and the Arabian and Red ſeas. That the ſouthern capes, promontories, and headlands were extenuated to their preſent ſhape by the deluge, and not by tides or the currents ſtill obſerved in thoſe ſeas, may be inferred from the inefficacy of thoſe feebler powers to produce any change in them for many paſt centuries.

The chief force of the inundation, continues our author, ſeems to have been directed northwards in the meridian of from 110 to 200 E. of London. In the more weſtern tracts it appears to have been weaker. The plains of India are ſuſpected to have been leſs ravaged, or perhaps their ſubſequent fertility may have been occaſioned by their numerous rivers. As to thoſe of Arabia, their ſolid baſis, reſiſting the inundation, was obliged to yield its looſer ſurface, and remains even now a ſandy deſert, while the interior more mountainous tracts, intercepting, and thus collecting, the waſhed-off ſoil, are to this day celebrated for their fertility, as Niebuhr teſtifies. To a ſimilar tranſportation of the ancient vegetable ſoil, the vaſt ſandy deſerts of Africa, and the barrenneſs of moſt of the plains of Perſia may be attributed. The progreſs of the Siberian inundation was for ſome time ſtationary, on account of its confinement between the Altaiſchan elevation on the ſouth, and the Ouralian mountains on the weſt, and the circumpolar mountains on the ſide of Greenland. Hence ariſe the excavations obſerved on the northern parts of the former, and the abrupt declivities on the eaſtern flanks of the latter, while the weſtern diſcover none. The maſs of waters collected and ſpread over the arctic regions muſt have deſcended partly ſouthwards over the deſerts of Tartary, into countries with which we have not much acquaintance, ſo as to be able to trace its ravages; but from the oppoſition it muſt have met with in thoſe mountainous tracts, and the repercuſſion of their craggy ſides, eddies muſt have been formed, to which the Caſpian, Euxine, and other lakes may have owed their origin. Part alſo muſt have extended itſelf over the vaſt tracts of the Ourals, and then expanded more freely over the plains of Ruſſia and Poland, down to latitude 52°, where it muſt have been oppoſed by the inundation originating in the weſtern parts of the Pacific ocean, on this ſide of the Cape of Good Hope, and thence impelled northwards and weſtwards, in the ſame manner as the eaſtern inundation already deſcribed, but with much leſs force, and ſweeping the continents of South America (if then emerged), and of Africa, conveying to Spain, Italy, and France, and perhaps ſtill further

Strahan and Preſton,
New-Street Square, London.

further north, elephants and other animals and vegetables hitherto ſuppoſed partly of Indian and partly of American origin. That the courſe here aſſigned is not imaginary, appears from the ſhells, vegetables, and animal remains of thoſe remote climates, ſtill found in Europe, and from the diſcovery both of the European and the American promiſcuouſly mixed with each other at Fez. So alſo in Germany, Flanders, and England, the ſpoils of the northern climates, and thoſe of the ſouthern alſo, are equally found; thus the teeth of arctic bears, and bones of whales, as well as thoſe of animals of more ſouthern origin, have been diſcovered in thoſe parts.

The encounter of ſuch enormous maſſes of water in oppoſite directions muſt have produced a ſtupendous effect; ſuch as appears to have been ſufficient for ſhaking and ſhattering ſome of the ſolid vaults that ſupported the ſubjacent ſtrata of the globe. To this concuſſion Mr. Kirwan aſcribes the formation of the bed of the *Atlantic*, which ſee. The wreck of ſo conſiderable an integrant part of the globe muſt neceſſarily have convulſed the adjacent ſtill ſubſiſting continents previouſly connected with it, rent their ſtony ſtrata, burſt the ſtill more ſolid maſſes of their mountains, and thus in ſome caſes framed, and in others prepared, the inſular ſtate to which theſe fractured tracts were reduced. To this event our author, therefore, aſcribes the bold, ſteep, and abrupt weſtern coaſts of Ireland, Scotland, and Norway, and the numerous iſles that border them, as well as many of thoſe of the Weſt Indies. The Britannic iſlands ſeem to have acquired, ſays Mr. Kirwan, their inſular ſtate at a later period, though it was probably prepared by this event; but the baſaltic maſſes on the Scotch and Iriſh coaſts, and thoſe of Feroe appear to him to have been rent into pillars by this concuſſion. During this elemental conflict, and the craſh and ruin of the ſubmerged continent, many of its component parts muſt have been reduced to atoms, and diſperſed through the ſwelling waves that uſurped its place. The more liquid bitumens muſt by the agitation have intimately mixed with them. They muſt alſo have abſorbed the fixed air contained in the bowels of the ſunk continent; and farther, by this continental depreſſion, whoſe derelinquiſhed ſpace was occupied by water, the level of the whole diluvial ocean muſt have been ſunk, and the ſummits of the higheſt mountains muſt then have emerged. In this ſtate of things it is natural to ſuppoſe that if iron abounded in the ſubmerged continent, as it does at this day in the northern countries of Sweden, Norway, and Lapland adjacent to it, its particles may have been kept in ſolution by the fixed air, and the argillaceous, ſiliceous and carbonaceous particles may have been long ſuſpended. Theſe muddy waters mixing with thoſe impregnated with bitumen, the following combinations muſt have taken place. 1. If carbonic matter was alſo contained in the water, this uniting to the bitumen muſt have run into maſſes no longer ſuſpenſible in water, and formed ſtrata of coal. 2. The calces of iron by the contact of bitumen were in great meaſure gradually reduced, and together with the argillaceous and ſiliceous precipitated on the ſummits of ſeveral of the mountains not yet emerged, and thus formed baſaltic maſſes, that during deſiccation ſplit into columns; in other places they covered the carbonaceous maſſes already depoſited, and by abſorbing much of their bitumen rendered them leſs inflammable, and hence the connection which the ſagacious Werner obſerved between baſalts and coal. The fixed or oxygen air, erupting from many of them, formed thoſe cavities, which being filled by the ſubſequent infiltration of ſuch of their ingredients as were ſuperfluous to their baſaltic ſtate, formed chalcedonies, zeoliths, olivins, baſaltines, ſpars, &c. Hence moſt of the mountains of Sweden that afford iron, afford alſo bitumen. Hence alſo the aſphalt found with trap, and under baſalts, and in balls of chalcedony found in trap. This Mr. Kirwan conceives to be the laſt ſcene of this dreadful cataſtrophe; and hence no ſhells are found in theſe baſalts, thoſe having been previouſly depoſited, though ſome other lighter marine vegetable remains have ſometimes been found in them; ſome argillaceous or ſand-ſtone ſtrata may alſo have been depoſited at this period.

To the Moſaic account it has been objected, that the countries near Ararat are too cold to bear olive-trees. Tournefort, who firſt made this objection, ſhould have recollected, that at this early period the Caſpian and Euxine ſeas were joined, as he himſelf has proved. This circumſtance fitted a country lying in the 38th degree of latitude to produce olives, which now grow in much higher latitudes, at preſent chilled only by its diſtance from the ſea. (See ARARAT.) A more plauſible objection ariſes from the difficulty of collecting and finding all the various ſpecies of animals now known, ſome of which can exiſt only in the hotteſt, and others only in the coldeſt climates. But it is not neceſſary to ſuppoſe that any others were collected in the ark beſides thoſe moſt neceſſary for the uſe of man, and thoſe only of the graminivorous or granivorous claſſes; Mr. Kirwan ſuggeſting that the others were probably of ſubſequent creation. At this early period ravenous animals were not only not neceſſary, but would have been even deſtructive to thoſe who had juſt obtained exiſtence, and probably not in great numbers. They only became neceſſary when the graminivorous had multiplied to ſo great a degree that their carcaſſes would have ſpread infection. Hence our author is led to ſuppoſe that they were of poſterior creation; and to this circumſtance he alſo attributes the exiſtence of thoſe that are peculiar to America, and the torrid and frigid zones. Among the ſubſequent effects of the flood we may mention the following: the atmoſphere muſt have been exceedingly altered by its conſequences. Soon after the creation of vegetables, and in proportion as they grew and multiplied, great quantities of oxygen muſt have been thrown off by them into the atmoſphere without any proportional counteracting diminution from the reſpiration or putrefaction of animals, as theſe were created only in pairs and multiplied more ſlowly; hence it muſt have been much purer than at preſent; and to this circumſtance in a great meaſure Mr. Kirwan inclines to aſcribe the longevity of the antediluvians. After the flood the ſtate of things was reverſed; the ſurface of the earth was covered with dead and putrefying land animals or fiſh, which copiouſly abſorbed the oxygenous part of the atmoſphere and ſupplied only mephitic and fixed air: thus the atmoſphere was probably brought to its actual ſtate, containing little more than one-fourth of pure air, and nearly three-fourths of mephitic. Hence the conſtitution of men muſt have been weakened, and the lives of their enfeebled poſterity gradually reduced to their preſent ſtandard. In order to avoid theſe exhalations it is probable that the human race continued for a long time to inhabit the more elevated mountainous tracts. Domeſtic diſturbances in Noah's family, briefly mentioned in the ſacred writings, probably induced him to move with ſuch of his deſcendants as were moſt attached to him to the regions he inhabited before the flood, which Mr. Kirwan conceives to have been the vicinity of China, and to this circumſtance he attributes the early origin of the Chineſe monarchy.

After all, whatever might be the inſtrumental phyſical cauſe of the deluge, and whatever might be the mode of its operation, we muſt on this occaſion have recourſe to a divine interpoſition and energy. For though the waters which covered the earth at the creation might be ſufficient

Straban and Preſton,
New-Street Square, London.

to cover it again, yet it is not eaſy to conceive or ſatisfactorily to explain, on any hypotheſis, how this could be effected by mere natural means. The waters, which were ſuſpended in the clouds, might, indeed, deſcend upon the earth, and that in cataracts, or ſpouts of water, as the Septuagint interprets "the windows of heaven," and thus a great inundation might be occaſioned in the lower grounds; but as the clouds could pour down no more water than they contained, which would ſoon be exhauſted, though it ſhould ſeem, from the long continuance of rain, that the ſhowers were rather moderate and gradual. The ſubterraneous ſtores would afford a more plentiful ſupply, but it is difficult to account for their being raiſed and perhaps more difficult afterwards to diſpoſe of and remove them. Whilſt we are unable to aſſign any natural cauſe that would be effectual for this purpoſe, we may reſolve it into the divine power, which might, on this occaſion, ſo far controul the uſual courſe of nature, as to effect this purpoſe. And, indeed, the event was ſo extraordinary, and the conſequences ſo conſiderable, that it is very reaſonable to believe, that God did, in a ſpecial manner interpoſe. Nevertheleſs, we can by no means adopt the opinion of M. Buffon, that to attempt an explanation of the univerſal deluge and of its phyſical cauſes; to pretend to give a detail of what paſſed during this great revolution; and to conjecture what effects have reſulted from it; indicate a preſumptuous deſire of ſcanning the power of the Almighty. The power of the Almighty was no leſs conſpicuouſly and miraculouſly diſplayed in the cataſtrophe of the deluge, though in accompliſhing his purpoſe, he directs and actuates the operation of phyſical cauſes or ſuſpends and controuls any of the eſtabliſhed laws of nature. The inquiry into the *modus operandi*, conducted with modeſty, and with a conſtant regard to the Moſaic account of this extraordinary event, by no means implies a doubt, much leſs a diſbelief of the agency of the omnipotent and all-wiſe ſovereign of nature, nor juſtifies thoſe charges of infidelity, that have been too freely and uncandidly made on thoſe who inveſtigate this diſpenſation of divine Providence. "It may ſtill be urged," ſays this ingenious writer, (Nat. Hiſt. by Smellie, vol. i. p. 131.) "that, as the univerſal deluge is an eſtabliſhed fact, is it not lawful to reaſon upon its conſequences? True. But you muſt commence with acknowledging that the deluge could not poſſibly be the effect of any phyſical cauſe; you muſt regard it as an immediate operation of the Deity; you muſt content yourſelf with what is recorded in Scripture; and you muſt, above all, avoid blending bad philoſophy with the purity of divine truth. After taking theſe precautions, which a reſpect for the counſels of the Almighty requires, what remains for examination, upon the ſubject of the deluge? Do the ſacred writings tell us, that the mountains were formed by the deluge? They tell us the reverſe. Do they inform us that the agitation of the waters was ſo great, as to raiſe the ſhells from the bottom of the ocean, and to diſperſe them over the face of the earth? No: the ark moved gently on the ſurface of the waters. Do they tell us, that the earth ſuffered a total diſſolution? By no means, the narration of the ſacred hiſtorian is ſimple and true; that of naturaliſts is complicated and fabulous." See *Theory of the* EARTH, and STRATA.

DELVIN, in *Natural Hiſtory*, a name ſometimes given by the miners in Cornwall to that ſort of talcy ſtone or ſlate, which they more generally call *killas*; but in ſome places, as at Lowancowiggan, they uſe it as the name of a coarſe, but very hard ſtone, in which the ore lies. The ore is tin, and is conſiderably rich there, but the hardneſs of the ſtone makes it difficult to be got out.

DELVIN, in *Geography*, a town of European Turkey, in the province of Albania; 36 miles S. W. of Delfino.

DELVING, in *Agriculture*, a word which implies the operation of digging, or turning up the ſoil by means of a ſpade.

DEMA, in *Geography*, a river of Ruſſia, which runs into the Bielaia, at Upha.

DEMADES, in *Biography*, an Athenian orator, originally a mariner, was taken priſoner by Philip of Macedon: he was a man of corrupt principles, but was far-famed for his eloquence and powers of perſuaſion. He checked king Philip in his immoderate exultation after the battle of Chæronea, charging him with acting the part of a Therſites, inſtead of imitating the more noble conduct of an Agamemnon. Philip took the rebuke in good part and made Demades his confidential friend. He ſided with the Macedonian party againſt Demoſthenes and the other patriots. When Alexander inflicted his vengeance upon Thebes, and demanded that the Athenians ſhould deliver up the orators and leading men who were his oppoſers, Demades completely diverted his wrath by obtaining a decree that the Athenians themſelves ſhould puniſh the guilty by their own laws, and he went at the head of an embaſſy to Alexander, who received them with great affability and admitted the Athenians to his favour. Demades was ſeveral times fined for propoſing edicts contrary to law, and was at one time declared infamous, and incapable of ſpeaking in the public aſſembly. He however recovered his authority, and was the means of carrying the decree by which Demoſthenes was condemned to death. So mercenary was Demades, that Antipater was accuſtomed to ſay, that of his two Athenian friends, he could get Phocion to accept of nothing, and could never ſatisfy Demades. He was as profuſe in ſpending, as rapacious in acquiring a fortune. He at length paid the penalty of his crimes: being ſuſpected of a traitorous correſpondence with the enemies of his country, his letters were intercepted, and himſelf was condemned to death, having previouſly had the mortification of ſeeing his own ſon killed. According to Cicero, Demades poſſeſſed in his ſpeeches more of the Attic ſalt than any other orator. He was extremely ready at extempore addreſſes and has occaſionally ſupported Demoſthenes when that prince of ſpeakers was thrown into confuſion by popular tumult. A ſpecimen of his ſtrong and pointed manner of ſpeaking is recorded upon the arrival of the news of Alexander's death. Demades refuſed to give any credit to the report; "for," ſaid he, "if Alexander were dead, the whole world would ſmell of the carcaſe." Univer. Hiſt.

DEMAIA, in *Geography*, a town of Egypt; 6 miles N. W. of Manſora.

DEMAIN, or DEMESNE, in its popular ſenſe, denotes the lord's manor-place, with the lands thereto belonging; which he and his anceſtors have from time to time kept in their own manual occupation. See MANOR.

DEMAIN, or *Demeſne*, in a law-ſenſe, ſignifies, according to Hottoman, patrimonium domini, the lord's patrimony; called alſo domain, and by the civilians, dominicum.

The ſame author proveth thoſe lands to be demain, which a man holdeth originally of himſelf; and thoſe to be feodum, which he holdeth of a ſuperior lord.

In England, no common perſon has any demain, ſimply underſtood; for all depends, either mediately or immediately, on the crown. When a man therefore, in pleading, would ſignify his land to be his own, he ſaith, that he is or was ſeiſed thereof in his demain, as of fee; whereby he means, that although his land be to him, and his heirs for ever, yet it is no true demain, but depends upon a ſuperior lord, and he

he holdeth by ſervice, or rent in lieu of ſervice, or by both ſervice and rent. Lit. l. i. c. 1.

DEMAIN is ſometimes alſo taken, more largely, for lands and tenements held for life, &c. and ſometimes more ſtrictly for ſuch only as are generally held in fee.

DEMAIN is ſometimes again uſed for a diſtinction between thoſe lands that the lord of the manor has in his own hands, or in the hands of his leſſee, demiſed upon a rent, for a term of years or life; and ſuch other lands pertaining to the ſaid manor which belong to the free, or copy-holders.

The reaſon why the copy-hold is accounted demain, is becauſe they, who are tenants to it, are judged in law to have no other right but at the will of the lord; ſo that it is reputed ſtill, after a ſort, to be in the lord's hands; and yet in common ſpeech that is ordinarily called demain, which is neither free nor copy-free.

DEMAIN, or *Demeſne*, again, is uſed in a more ſpecial ſignification, in oppoſition to frank-free lands.

Thus, thoſe lands, or manors, which were in the poſſeſſion of Edward the Confeſſor, or William the Conqueror, are called ancient demain, or demeſne; and all others are called frank-fee; and the tenants who hold any of thoſe former lands, are called tenants in ancient demain; and the others, tenants in frank-fee, and alſo tenants at common law. The reaſon is, becauſe tenants in ancient demain cannot be ſued out of the lord's court. The tenants of theſe lands, under the crown, were not all of the ſame order or degree. Some of them, as Britton teſtifies (c. 66.), continued for a long time pure and abſolute villeins, dependent on the will of the lord; and thoſe who have ſucceeded them in their tenures now differ from common copy-holders in only a few points. (F. N. B. 228.). Others were in great meaſure enfranchiſed by the royal favour; being only bound in reſpect of their lands to perform ſome villein ſervices of the better ſort, which were determinate and certain; as, to plough the king's land for ſo many days, to ſupply his court with ſuch a quantity of proviſions, or other ſtated ſervices; all which are now changed into pecuniary rents; and in conſideration of theſe, they had many immunities and privileges granted them (4 Inſt. 269.); as, to try the right of their property in a peculiar court of their own, called a court of ancient demeſne, by a peculiar proceſs denominated a writ of "right cloſe;" not to pay toll or taxes; not to contribute to the expences of knights of the ſhire; not to be put on juries; and the like. (F. N. B. 11. 14.) Theſe tenants therefore, though their tenure be abſolutely copyhold, yet have an intereſt equivalent to a freehold; and lands holden by this tenure are a ſpecies of copyhold, and as ſuch preſerved and exempted from the operation of the ſtatute of Charles II.; yet they differ from common copyholds, principally in the forementioned privileges; and they differ from freeholds by one ſpecial mark of villenage, noted by Bracton, and remaining to this day; *viz.* that they cannot be conveyed from man to man by the general common law conveyances of feoffment, and the reſt; but muſt paſs by ſurrender to the lord or his ſteward, in the manner of common copyholds; with this diſtinction however, that in the ſurrender of theſe lands in ancient demeſne, it is not uſed to ſay "to hold at the will of the lord" in their copies, but only "to hold according to the cuſtom of the manor."

DEMAIN, or *Demeſne*, lands of the crown, *terræ dominicales regis*, denote either the ſhare reſerved to the crown in the diſtribution of landed property, or ſuch as came to it afterwards by forfeitures or other means, which were anciently very large and extenſive; compriſing divers manors, honours, and lordſhips; the tenants of which had very peculiar privileges. At preſent they are contracted within a very narrow compaſs, having been almoſt entirely granted away to private ſubjects. This has occaſioned the parliament frequently to interpoſe; and, particularly, after king William III. had greatly impoveriſhed the crown, an act paſſed (1 Ann. ſt. 1. c. 7.) whereby all future grants or leaſes from the crown for any longer term than 31 years or three lives are declared to be void; except with regard to houſes, which may be granted for 50 years. And no reverſionary leaſe can be made, ſo as to exceed, together with the eſtate in being, the ſame term of three lives or 31 years; that is, when there is a ſubſiſting leaſe, of which there are 20 years ſtill to come, the king cannot grant a future intereſt, to commence after the expiration of the former, for any longer term than 11 years. The tenant muſt alſo be made liable to be puniſhed for committing waſte; and the uſual rent muſt be reſerved, or, where there has uſually been no rent, one-third of the clear yearly value. The rents and profits of the demeſne lands of the crown conſtitute one branch of the king's ordinary revenue.

DEMAND, in its proper ſenſe, denotes a calling for, or requiring one's due.

DEMAND in *Law*, has a more ſpecial ſignification, as contradiſtinguiſhed from plaint: for all civil actions are purſued either by demands or plaints; according to which the purſuer is called either demandant or plaintiff; *viz.* in real actions, demandant; and in perſonal actions, plaintiff.

Where the party purſuing is called demandant, the party purſued is called tenant; and where the former is called plaintiff, the latter is termed defendant.

There are two kinds of demands: the one in deed, *de facto*, as in every precipe; the other in law, *de jure*; ſuch is entry in land, diſtreſs for rent, &c.

As an entry on land, and taking a diſtreſs, are a demand in law of the land and rent, ſo the bringing of an action of debt for money due on an obligation is a demand in law of the debt. (1 Litt. 432. 1 Nelſ. Abr.) Debts, claims, &c. are to be *demanded* and made in time, by the ſtatute of limitations; (21 Jac. 1. c. 16.) and other ſtatutes; or they will be loſt by law. A demand muſt be legal, and made in ſuch a manner as the law requires: if it be for rent of a meſſuage and lands, it ought to be made at the meſſuage, at the fore door of the houſe, the moſt notorious place; where lands and woods are let together, the rent is to be demanded on the land, as the moſt worthy thing, and on the moſt public part thereof: if wood only be leaſed, the demand muſt be made at the gate of the wood, &c. (1 Inſt. 201. Poph. 58.)

If a man releaſe another from all demands, it is the beſt releaſe the releaſee can have, and ſhall redound moſt to his advantage: for all executions, and all freeholds, and inheritances, executory, are releaſed. A releaſe of facts is more large than of quarrels or actions; and a releaſe of demands more large and beneficial than either: by a releaſe of all demands to the diſſeiſor, the right of entry into the land, and all contained therein, is releaſed; and he that releaſeth all demands, excludes himſelf from all actions, entries, and ſeizures. But it is no bar to a writ of error to releaſe an outlawry. 8 Co. 153, 154.

DEMANDANT, PETENS, he who is actor, or plaintiff, in a real action; thus called, becauſe he demands lands, &c.

DEMANOVO, in *Geography*, a great cavern in a limeſtone rock, near the town of Pribilini in Hungary. This is the cave of which Bruchman, in his Epiſtola Itineraria, Ep. 77. aſſerts, that it is full of bones, and out of which was taken the ſkeleton of the dragon belonging to the king of Saxony at Dreſden. Townſon's Hungary.

DEMARATUS, in *Biography*, king of Sparta, ſucceeded his father Ariſto: and had, almoſt as ſoon as he aſcended

the throne, to encounter the violent meaſures of Cleomenes his colleague, who, in revenge, endeavoured to perſuade the Lacedæmonians that he was not the real ſon of Ariſto, and, of courſe, had no right to the crown which he wore. The oracle was applied to, to determine the queſtion, which Cleomenes had found means to corrupt. The deciſion was againſt Demaratus, and he was depoſed: he was, however, too much of a philoſopher to be greatly diſturbed at being reduced to the ſtate of a private life: he ſubmitted to his fate with becoming dignity, and was ever willing to ſerve his country in ſubordinate offices. Demaratus was alſo celebrated for his activity in athletic exerciſes, and is ſaid to have been the only ſovereign of Sparta who gained a prize at the Olympic races. Owing to ſome inſults which he met with from his ſucceſſor, he determined to quit Sparta, and retire into Aſia. He was received with kindneſs by Darius Hyſtaſpis, about the year 492, B. C. who treated him in a manner becoming his former royal rank, and made him great preſents. At the death of Darius, his friend and protector, he is ſaid to have aſſiſted Xerxes in the ſucceſſion: he was, however, ſtill ſo firmly attached to his country, that when he underſtood meaſures were taken by the Perſians to injure it, he communicated the buſineſs, by means of a pair of writing tables, on the wood of which he had cut an account of the fact, and covered the letters over with wax. Little more is known of Demaratus, except that his family flouriſhed in Perſia many generations with reſpect and honour. Another perſon of the ſame name was a citizen of Corinth, and is quoted by many of the ancients as the author of ſeveral treatiſes. Plutarch, in his own diſcourſe on rivers, refers to one on the ſame ſubject by Demaratus. Moreri.

DEMARCHUS, in *Antiquity*, the chief of a region, or diſtrict, in the country of Attica.

The Athenians divided their country into certain regions, or diſtricts, which they called δημοι, *i. e. people*; and eſtabliſhed a magiſtrate at the head of each, under the denomination of δημαρχος, *demarchos*, of δημος, and αρχη, *rule, government*.

It was alſo an appellation given to the chief magiſtrate of the city Neapolis.

DEMAVEND, in *Geography*, a town of Perſia, in the province of Irak; 170 miles E. of Amadan.

Demavend is alſo a range of mountains in Perſia, dividing Hyrcania from Parthia, according to Chardin; that is, in other words, the mountains of Mazendran. D'Anville marks Demavend due W. of Iſpahan, and it is repreſented as one of the chief elevations, which affords a proſpect of 50 farſangs, or 200 miles.

DEMBEA, a province of Abyſſinia, near a lake of the ſame name, ſituated between 11 degrees and 12 degrees N. lat. and 36 and 37 degrees E. long. below the mountains bounding Gueſqué and Kuara. This low province, and Woggora, a ſmall high province on the eaſt, are all ſown with wheat, and are the granaries of Abyſſinia. Dembea, according to Mr. Bruce, ſeems once to have been occupied entirely by the lake. It is called Atté-Kolla, the king's food, or maintenance; its produce being aſſigned for the ſupply of the king's houſehold. It is governed by an officer called Cantiba; whoſe poſt is lucrative; but he is not reckoned one of the great officers of the empire, and has no place in council.

Dembea, or Tzana, a lake of Abyſſinia, which is the largeſt expanſe of water known in that country. Its extent, however, ſays Mr. Bruce, (Travels, vol. iii. p. 387.) has been greatly exaggerated. Its greateſt breadth, from Dingleber to Lamgué, in a line nearly E. and W. is 35 miles; but it decreaſes much at each extremity, where it is not in ſome places above 10 miles broad. Its greateſt length is from Bab Baha to a little S. W. by W. of that part where the Nile, after having croſſed the end of it by a current always viſible, turns towards Dara, in the territory of Alata, which is 49 miles from N. to S. and which is the extent of this lake in length. In the dry months, from October to March, the lake very much ſhrinks in ſize; but after all the rivers on every ſide of it are filled, and have fallen into the lake, like radii drawn to a centre, it then ſwells, and extends itſelf into the plain country, and of courſe has a much larger ſurface. It contains, according to the fabulous reports of the Abyſſinians, 45 inhabited iſlands; but Mr. Bruce conceives the number to be about 11; the principal of which is Dek, or Daga, ſignifying a hill or high ground, nearly in the middle of the lake. Other iſlands are Halimoon nearer Gondar, and Briguida nearer Gorgona. All theſe iſlands were formerly uſed as priſons for the great people, or for a voluntary retreat on account of ſome diſguſt or great misfortune, or as places of ſecurity to depoſit their valuable effects, during troubleſome times. When Mr. Bruce was in Abyſſinia, 1300 ounces of gold, confided by the queen to Welleta Chriſtos, her governor of Dek, a man of extraordinary ſanctity, who had faſted for 40 years, was ſtolen away by that prieſt, who fled and hid himſelf; but the queen would not ſuffer him to be ſearched after or apprehended.

DEMEMBRE', in *Heraldry*, is when an animal is diſmembered, *i. e.* the limbs cut off its body.

DEMER, in *Geography*, a river of France, which has its ſource in the department of the Lower Meuſe, to the weſt of Maeſtricht, paſſes by Dieſt, Sickem, and Aerſchot, and falls into the Dyle, between Louvain and Malines. Timber and firewood are ſent by the Demer to Malines, Antwerp, and Bruſſels from Dieſt, but the boats or floats muſt be haled.

DEMERARA, a river of South America, in the country called Dutch Guiana or Surinam, which after a ſhort courſe diſcharges itſelf into the Eſquivo. The mouth of this river is defended by fort William Frederic; and the Dutch have formed a ſettlement on its banks, near which the inhabitants cultivate ſugar, cotton, and coffee. This river is about two miles wide at its mouth, oppoſite to the fort on its eaſt bank; and nearly a mile wide, 12 miles above the fort; its courſe is from S. to N., and it is navigable about 200 miles for veſſels that can paſs the bar at its mouth, which is a mud bank, not having above 24 feet at the higheſt water. The fort, properly ſupplied with men and ammunition, might be able effectually to guard its entrance. Staebroeck, the ſeat of government, is ſituated on the eaſt ſide of the river, 1½ mile above the fort. The diſtrict of Demerara, together with Eſſequibo, form one government, and have the ſame court of police, but each has a ſeparate court of juſtice. The two diſtricts contain about 3000 whites, and 40,000 ſlaves. The river paſſes through the diſtrict, and whilſt it was in the poſſeſſion of the Dutch, was uſually viſited by 40 or 50 large ſhips from Holland, which often made two voyages in a year, beſides more than 250 ſmaller veſſels, under the Dutch and other flags. The plantations are regularly laid out in lots along the ſhore, called façades, about one-fourth of a mile wide, and extending three-fourths of a mile back into the country. Each lot includes about 250 acres, containing, when fully cultivated, 120,000 cotton trees, yielding generally at an average half a pound each tree, and employing 120 negroes. The ſhores of the rivers and creeks are chiefly planted with coffee, to the diſtance of about 30 miles from the ſea; from thence to the diſtance of 30 miles further, the ſoil becomes clayey and more fit for ſugar. Beyond this, the fineſt kinds

of

of wood, for building, furniture, &c. are obtained. N. lat. 6° 40′. W. long. 57° 45′.

DEMEROSESA, in *Ancient Geography*, a town of the iſland of Albion, ſuppoſed by Gale to be Dumfries.

DEMERSUM Folium. See Leaf.

DEMESNE, in *Law*. See Demain.

DEMETÆ, in *Ancient Geography*, were inhabitants of South Wales, ſeated, according to Ptolemy, next to the Silures, and poſſeſſed that part of the country, which is now divided into Caermarthenſhire, Pembrokeſhire, and Cardiganſhire; to which Baxter thinks Brecknockſhire and Radnorſhire ſhould be added. This country is called by ſome of the moſt ancient of our monkiſh writers, Demetia, from the name of its inhabitants; and it is not improbable, that they and their country derived their name from "Deveit," or Defaid, which ſignifies ſheep, which very much abounded in thoſe parts. As neither Pliny, Tacitus, nor any ancient writer, except Ptolemy, mentions any other nation in South Wales but the Silures, it ſeems probable that the Demetæ were generally conſidered as a part of that nation, and were perhaps their Cangi, or the keepers of their flocks and herds. Admitting this conjecture, the Demetæ were perhaps that nation of Cangians that were ſubdued by Oſtorius Scapula, after he had defeated the Iceni. For the country of theſe Cangians reached to the Iriſh ſea, which very well agrees with the ſituation of Demetia, (Tacit. An. l. xii. c. 33). As the Demetæ did not reſiſt the Romans with much obſtinacy, and as their country lay in a remote corner, and was then, and long after, very wild and uncultivated, it ſeems to have been little frequented by theſe conquerors, who had very few towns or ſtations within its limits. As none of the journies of Antoninus lay through any part of the country of the Demetæ, no place in that country is mentioned in the Itinerary. Ptolemy takes notice of the promontory Octapitarum, now St. David's Head, at the mouth of the river Tobius, now the Towy in Caermarthenſhire, and of the towns Luentium or Luentinum, now Llan-Ddewy-Brevy, in Cardiganſhire, near which Roman coins and bricks have been found, and Maridunum, now Caermarthen. The country of the Demetæ was ſituated in the Roman province called Britannia Secunda.

DEMETRIA, Δημητρια, in *Antiquity*, a feſtival in honour of Ceres, called by the Greeks *demeter*, δημητηρ, of δη, *i. e.* γη, *earth*, and μητηρ, *mother*. It was uſual on this occaſion for the worſhippers to laſh themſelves with whips made of the bark of trees, and called μυροπτοι. Pott. Archæol. Græc. tom. i. lib. ii. cap. 20. p. 379.

Demetria was likewiſe the name of another feſtival celebrated by the Athenians in honour of Demetrius Poliorcetes, and was the ſame with that afterwards called Dionyſia. Pott. loc. cit.

DEMETRIAS, in *Ancient Geography*, a town of Greece, in Theſſaly.—Alſo, a name given to the town of Sicyonia.—Alſo, a town of Aſia, in Syria, ſituated near to and eaſt of the Mediterranean ſea.—Alſo, a town of Aſia, now *Kerkouk*, near the mountains and S.S.E. of Arbela. It is called *Corcura* by Ptolemy.

DEMETRIUM, a place of Theſſaly, near the Pelaſgian gulf, where was a grove ſacred to Ceres.—Alſo, a port in the northern part of the iſle of Samothrace, near the promontory of the ſame name.

DEMETRIUS I. in *Biography*, ſurnamed Poliorcetes, king of Macedon, was ſon of Antigonus, a captain under Alexander the Great, and one of his ſucceſſors. He was born about the year 340 B.C. In one of his firſt military eſſays he was unſucceſsful. Ptolemy having invaded Syria, Demetrius was ſent with an army to oppoſe him, and was completely defeated at Gaza. Soon after, another opportunity was given him of retrieving his character which he did by vanquiſhing Ptolemy's general, taking him priſoner, with his camp and military treaſures. Towards the conquered he behaved with much kindneſs and generoſity. Demetrius afterwards made an expedition into Arabia. He next drove Seleucus from Babylon, laid waſte the country, and, returning, obliged Ptolemy to raiſe the ſiege of Halicarnaſſus. A treaty was immediately entered into between Antigonus and the princes confederated againſt him, which was ſoon broken; and Demetrius from this time ſet himſelf to deliver Greece from the tyranny under which it had long laboured. He landed at Athens, and after various ſucceſs he aſſembled the people, and ſolemnly reſtored their ancient democratic government; giving them, at the ſame time, large preſents of corn, timber, and other things of which they ſtood moſt in need. The Athenians in return for this liberality inveſted their benefactors with the higheſt honours; rendering them the homage due to guardian deities, and appointing a prieſt to ſerve them. From Greece, Demetrius proceeded to carry on another war againſt Ptolemy. He raiſed an army in Cilicia, and aſſembling a numerous fleet, proceeded to Cyprus. Here he defeated Menelaus the brother of Ptolemy, and beſieged him in the town of Salamis. Ptolemy came with a large fleet in aid of his brother, and a naval engagement enſued, in which the whole force of Ptolemy was almoſt entirely deſtroyed, and he was obliged to return to Egypt with eight galleys only. The whole iſland, with all the warlike ſtores and magazines, fell into the hands of the victor: and Menelaus and his ſon were among the priſoners; but theſe, with a genuine greatneſs of mind, he liberated without a ranſom. Antigonus henceforth aſſumed the title of king, and gave it alſo to his ſon. Among the female captives was Lamia, a celebrated courtezan, who captivated the heart of Demetrius, and who long retained over him a complete aſcendency. His gallantry, however, never permitted him to forget the buſineſs of war. He was an able mechanician, and applied his knowledge to the conſtruction of military engines, that were particularly uſeful to him in the various ſieges which he undertook, and in which he was generally ſucceſsful; though at Rhodes his ſkill was baffled, and he was obliged to retire after he had continued before the place more than a year. From Rhodes he went again to the aſſiſtance of the Athenians againſt Caſſander. In this inſtance, as before, his ſucceſs was perfect, and he reſtored liberty to all the Greek ſtates ſouth of Thermopylæ. He then took up his quarters at Athens, where his good fortune, and the high reputation which he had acquired, drew from the citizens the moſt ſervile adulation, which incited him to all kinds of extravagance and the groſſeſt debauchery. His influence with the Athenians cannot be better ſhewn than by obſerving, that when he demanded to be initiated into their myſteries, which could only be done at certain periods of the year, they actually changed the names of two of their months to accommodate his wiſhes. Demetrius was called from Greece by his father, againſt whom a league was formed by Caſſander, Seleucus, and Lyſimachus. In the battle of Ipſus, B.C. 301, his impetuoſity led him into difficulties, and he was glad to retreat to Epheſus, from which place he embarked for Greece, intending to proceed to Athens, but that city, which but a ſhort time before had paid him a kind of adoration due only to a celeſtial being, refuſed him admittance, and diſmiſſed his wife with her retinue. This event affected him very much; and he blockaded Athens, which after enduring the horrors of famine ſubmitted. He treated the vanquiſhed city with an unexpected lenity, and preſented it with a large ſupply of corn.

corn. After other exploits he was applied to by Alexander, the ſon of Caſſander, lately dead, to aſſiſt him againſt his brother Antipater: whether he rendered him any effectual aid does not appear, but it is certain that at the inſtigation of Demetrius, Alexander himſelf was aſſaſſinated at a banquet; and the baſe action was rewarded by ſucceſſion to the throne of Macedon. In this high ſtation he acted ſo imprudently, and with ſo little attention to the intereſts of his ſubjects, that after ſix years he was obliged to abandon the robes of royalty, and the kingdom over which he had reigned. The changes to which Demetrius was ſubject during the remainder of his life were very great; ſometimes at the head of powerful armies, at others left without a ſingle attendant. At length he was made priſoner by Seleucus, who kept him under a ſtrict guard in a caſtle in the Syrian Cherſoneſus. In this ſituation he had the affecting conſolation of finding his own ſon, Antigonus, offering himſelf an hoſtage for the freedom of his father. Demetrius abandoned himſelf to drinking to diſpel the trouble and melancholy of captivity, which brought on diſeaſes that terminated his life in his fifty-fourth year. His remains were conveyed to Greece, where his funeral was celebrated with every circumſtance of ſolemn pomp. His poſterity filled the throne of Macedon till Perſes was conquered by the Romans. Demetrius was remarkable, as has been ſeen, for the ſplendour of his character, and the variety of his fortune. Univer. Hiſt.

Demetrius II. king of Macedon, grandſon of the former, and ſon of Antigonus, who, we have ſeen, offered himſelf a ranſom for his father's freedom. In his youth he was diſtinguiſhed for his valour, and when he aſcended the throne, he was chiefly occupied in war with barbarous nations on the frontiers of his own dominions. He died B. C. 232, leaving the crown to his ſon Philip, then an infant.

Demetrius I. king of Syria, ſurnamed *Soter*, ſon of Seleucus Philopater, was ſent hoſtage to Rome by his father, on whoſe death Antiochus Epiphanes, and after him his ſon Antiochus Eupator, the one the uncle, the other the couſin of Demetrius, uſurped the throne of Syria. Demetrius in vain ſought of the Roman ſenate liberty to return to his own country to aſſert his rights; what was refuſed to him as a right, he contrived to effect by ſtratagem; he made his eſcape from Rome with the aſſiſtance of Polybius the hiſtorian, and landed in Syria. He was acknowledged as ſovereign, and ſecured his crown by the death of Eupator, who fell into his hands. He freed the Babylonians from the tyrannical rule of two brothers, whom Antiochus had placed over them, on which account he was entitled *Soter*, or Saviour. He ſent his armies againſt the Jews, in order to make Alcimus high-prieſt, and in this conteſt Judas Maccabæus loſt his life. By his own conduct he united againſt him the kings of Cappadocia, Pergamus, and Egypt; in battle he was at firſt ſucceſsful, but his want of prudence rendered him obnoxious to his own ſubjects, who deſerted him in the hour of danger, and he loſt his life in battle, in the year B. C. 150.

Demetrius II. ſurnamed *Nicanor*, the ſon of the preceding, was placed on his father's throne by Ptolemy Philometor, king of Egypt, whoſe daughter Cleopatra he married. No ſooner had he obtained the quiet poſſeſſion of the crown, than he abandoned himſelf to every kind of diſſipation and licentiouſneſs, and left the management of his affairs to flatterers and paraſites. He afterwards formed an alliance with the Jews, and marched to the Eaſt, where he was taken priſoner by the king of Parthia, who beſtowed his daughter upon him in marriage, which ſo enraged Cleopatra, his former wife, that ſhe married her brother-in-law, who laid claim to, and obtained the throne for himſelf. Shortly after he fell in battle, when Demetrius recovered the kingdom of Syria. By the wickedneſs and cruelty of his conduct, he became univerſally hated, was driven from his throne, and at laſt put to death, by command of his wife Cleopatra, at Tyre, whither he had fled for refuge and ſafety. Univer. Hiſt.

Demetrius Phalereus, a philoſopher of the peripatetic ſect, and diſciple of Theophraſtus. About the year 317 B. C. he was appointed by Caſſander, king of Macedon, to the government of Athens, which he conducted for ten years with ſo much wiſdom and moderation, that he is ſaid to have obtained the honour of 360 brazen ſtatues, erected in remembrance of his juſtice and of the improvements introduced by him into the finances, and the public buildings with which he had ornamented the city. He afterwards fell into diſgrace, and his life being in imminent danger, he fled to the court of Ptolemy Soter, king of Egypt, who received him with marked reſpect; but diſapproving the advice he gave him, with reſpect to the choice of a ſucceſſor, the young prince, Philadelphus, retained a fixed enmity againſt him; ſo that upon the death of this king, Demetrius was baniſhed to a diſtant province, where he loſt his life by the bite of an aſp. He died about the year 284. Some have ſaid, without ſufficient authority, that he was librarian to Ptolemy Philadelphus, and that by his advice this prince gave orders for a verſion of the Jewiſh Scriptures from the Hebrew into the Greek language. He was author of a vaſt number of books in proſe and verſe, on philoſophy, hiſtory, politics, criticiſm, and rhetoric, but time has deſtroyed them all. The elegant piece, "De Interpretatione," which ſome have aſcribed to him, is probably a work of later date.

Demetrius Phalereus lived at a period ſucceeding that of Demoſthenes, when Greece loſt her liberty and eloquence, and of courſe languiſhing, relapſed again into the feeble manner introduced by the Rhetoricians and Sophiſts. However, he attained ſome character; but he is repreſented as a flowery, rather than a perſuaſive ſpeaker, who aimed at grace rather than ſubſtance. "Delectabat Athenienſes," ſays Cicero, "magis quam inflammabat." "He amuſed the Athenians, rather than warmed them." After his time we hear of no more Grecian orators of any note. Diogenes Laertius, lib. v. Brucker's Hiſt. Phil. by Enfield, vol. i.

Demetrius, a Cynic philoſopher, who flouriſhed at Corinth in the firſt century. During the reign of Caligula, he taught philoſophy at Rome, where he obtained the higheſt reputation for wiſdom and virtue. When Nero ſucceeded to the crown, Demetrius was baniſhed for his inflexible integrity and zeal in reproving the manners of the age. At his death he was recalled, but was again baniſhed for the boldneſs of his language. A high teſtimony to the character of Demetrius is given by Seneca, who ſays, "leaving the nobles clad in purple, I converſe with, and admire the half-naked Demetrius; and why do I admire him, but becauſe I perceive, that in the midſt of his poverty he wants nothing! When I hear this excellent man diſcourſing from his couch of ſtraw, I perceive in him, not a preceptor only, but a witneſs of the truth, and I cannot doubt, that Providence has endowed him with ſuch virtues and talents, that he might be an example, and a monitor of the preſent age." Moreri. Brucker's Hiſt. of Phil. by Enfield.

DEMEU, in *Geography*, a ſmall town of France, in the department of the Gers; ſix miles W. of Vic ſur Loſſe.

DEMI, in *French Muſic*, is equal to ſemi in the Engliſh, and in compoſition of the ſame import as ſemi, Lat. implying half any quantity or ſubſtance. Demi-god, half-mortal, half-divine.

Semi-quaver, half a quaver, in muſic. Demi-ſemi-quaver, half a ſemi quaver, a note in muſic with a black head, and three hooks, or three ties to the tails. Demi or ſemi is half the ſubſequent word.

Demi, or Demy, in *Heraldry*, ſignifies the half of a thing; as, a demy lion, &c.

Colombiere has what he calls croix & demy, a croſs and a half; being a ſhaft croſſed in the upper part like the Calvary croſs, and having but one arm at the lower part.

Demi-Air, or Demi-Volt, in *Horſemanſhip*, is one of the ſeven artificial motions of a horſe; being an air, in which his fore-parts are more raiſed than in terra à terra: but the motion of the horſe's legs is more quick in the latter than in the demi-volt.

DEMIANKA, in *Geography*, a river of Ruſſia, which runs into the Irtiſch, near Demianſkoi.

DEMIANSKOI, a town of Ruſſia, in the government of Tobolſk, ſituated at the conflux of the Demianka and Irtiſch, 100 miles N.N.E. of Tobolſk. N. lat. 59° 35′. E. long. 69° 22′.

Demi-Bastion, ſhould literally imply "half a baſtion," but ſuch would be a very weak defence, on account of the extreme acuteneſs of the angle preſented exteriorly at the point of diviſion; which would, if mathematically done, be effected by a line drawn from the centre of the polygon to the flanked angle, along the capital of the baſtion. To remedy this, the gorge is extended ſo as rather to exceed, than to be under, the meaſurement of the greateſt diameter; ſome make the gorge equal to the length of the face, by which means the new face, or capital, becomes an *acute*, inſtead of an *obtuſe* angle therewith.

Demi-baſtions are chiefly found in *horn-works*, and *crown-works*, and in the various junctions of faces, appertaining to regular fronts, with redans, and other irregular portions; eſpecially where they break off from the defence of land ſides, to the defence of rivers, &c. By this means the inland defences are preſerved in ſyſtematic order; while due advantage is taken of the form or height of a bank, &c. See Fortification.

Demi Cannon, a piece of ordnance, uſually about ſix inches bore, 5400 pounds weight, ten or eleven feet long, and carrying a ſhot of 30 or 32 pound weight.

It carries point-blank 150 paces; its charge of powder is 14 pound weight.

There are alſo two ſizes of demi-cannon above this, which are ſomething larger; as, the ordinary demi-cannon, which is ſix inches $\frac{1}{6}$ bore, twelve feet long, weighing 5600 pounds; its charge of powder 17 pounds 8 ounces; it carries a ſhot ſix inches and a half diameter, whoſe weight is 32 pounds: this piece ſhoots point-blank 162 paces.

Demi-cannon of the largeſt ſize, is 6 inches $\frac{6}{8}$ bore, twelve feet long, 6000 pounds weight; its charge is 18 pounds of powder, and it carries 180 paces. See Cannon, and Ordnance.

Demi-Cross, an inſtrument uſed by the Dutch to take the ſun's altitude, or that of a ſtar, at ſea; but inſtead of which we uſe the croſs-ſtaff or fore-ſtaff. See *Plate* V. *Aſtronomy, fig.* 46.

The ſtaff, A G, is graduated eaſily, being only a line of whole tangents, whoſe radius is E B, the length of the croſs-piece, or tranſom. It hath three vanes; a horizontal vane, as A; a ſight vane, as H; and the ſhade vane, as E.

When the vanes are on the ſtaff and croſs-piece, to take the ſun's altitude, hold the inſtrument with the tranſom as upright as you can, and looking through the ſight vane, as H, look for the horizon through the ſlit in the horizon vane, and then ſlide the croſs-piece or tranſom to and fro, till you make the ſhade of the vane at E to fall at the ſame time upon the ſlit of the horizon vane, and alſo at A; then are the degrees cut on the ſtaff, by the edge of the croſs-piece, the ſun's altitude required. But to take the height of a ſtar, you muſt remove the horizon vane, A, and put it on the end G, and transfer the ſight vane H to A; then holding up the inſtrument as before, looking through the ſight vane, ſee for the horizon through the horizon vane, and for the ſtar by the ſhade vane, ſliding the tranſom to and fro, till the horizon and ſtar are both ſeen by their reſpective vanes, and then the tranſom will cut the degrees of the ſtar's altitude on the ſtaff, allowing about eight or ten minutes for your height above the level of the water, as muſt be done in all ſuch caſes.

Demi-Culverin, is a piece of ordnance commonly $4\frac{1}{2}$ inches bore, ten feet long, 2700 pounds weight; its charge is 7 pounds 4 ounces of powder; and it carries a ſhot of 10 pounds 11 ounces, and ſhoots point-blank 175 paces.

Demi-culverin of the leaſt ſize, is $4\frac{1}{4}$ inches bore, ten feet long, 2000 pounds weight; it carries a ball of 4 inches diameter, its charge is 6 pounds 4 ounces of powder, and its level range is 174 paces.

Demi-culverin of the largeſt ſort, is 4 inches $\frac{6}{8}$ bore, ten ſeet long; its charge of powder is 8 pounds and 8 ounces; the ball is $4\frac{1}{2}$ inches diameter, weighs 12 pounds 11 ounces; and the point-blank ſhoots 178 paces. See Cannon and Ordnance.

Demi-Ditone, in *Muſic*, is uſed by ſome for a third minor.

Demi Gods, in *Mythology*, thoſe fabulous beings that were ſuppoſed to be produced by the connexion of gods with women, or of goddeſſes with men; of theſe there was a prodigious number, whoſe temples were diffuſed over the whole earth, and whoſe worſhip, though leſs ſolemn than that of the gods, formed a conſiderable part of the Pagan religion. See Genii, God, Heroes, Idolatry, and Theogony.

Demi-Gorge of a baſtion, is the half of the *gorge*, or neck of the baſtion, meaſured in a right line from the ends of the two curtains, or faces, between which the baſtion is ſituated. Where the mean and great ſyſtems of fortification are blended, the baſtions connecting the faces, which appertain to thoſe ſyſtems reſpectively, will be unequal in regard to the general proportions of their two ſides, and the gorge will be divided into two unequal parts by its capital; which paſſes in a right line from the flanked angle to the centre of the polygon; and where the polygon is drawn upon an ellipſis, or oval, and the defences are derived from two or more centres, the capital of each demi-baſtion will lead to a diſtinct point, *i. e.* the centre of its own derivation, and there will be found a ſpace between the two capitals, excluſive of two unequal demi-gorges. This, however, rarely occurs, and, when it does, is more a nominal than an eſſential difference; it being uſual to conſider a mean difference between the two, as the centre of the gorge, and to ſuppoſe the demi-gorges to meet at that point. See Fortification.

Demi-Haque. See Harquebuss.

Demi-Lune, is a defence uſually attached exteriorly to the poſterns of a raveline: they were formerly made of a creſcent form, whence their name; but the modern ſyſtem explodes all circular defences, except in the more petty claſs, ſuch as redoubts, block-houſes, cavaliers, &c. The demi-lune is now generally called the *lunette*; it is in general uſe, but is always made with a flanked angle, and not circular. See Fortification.

Demi-Quian, in *Geography*, a river, ſwamp, and lake, on the

the weſtern ſide of Illinois river in the N. W. territory. The river runs a S.S.E. courſe, is navigable 120 miles, and has the ſwamp of the ſame name on the northern bank near its mouth; which laſt is 50 yards wide, 32 miles above Sagamond, and 165 miles above the Miſſiſippi. The lake is of a circular form, 200 yards W. of the river, is 6 miles acroſs, and diſcharges itſelf into the Illinois by a ſmall paſſage four feet deep, 175 miles from the Miſſiſippi.

DEMIR-Capi, a town of Aſiatic Turkey, in the province of Natolia; 20 miles S.E. of Balikeſri.

DEMISE, in *Law*, is applied to an eſtate either in fee-ſimple, fee-tail, or for term of life, or years; and ſo it is commonly taken in many writs. It is alſo uſed for any eſtate. (2 Inſt. 483.)

The king's death is, in law, termed the demiſe of the king, to his royal ſucceſſor, of his crown and dignity.

Demise *of the king*, or *of the crown*, *demiſſio regis vel coronæ*, an expreſſion uſed for the natural diſſolution of the king, becauſe the law is tender of ſuppoſing even the poſſibility of his death, and which ſignifies merely a transfer of property, for the king never dies. (See King.) Plowden obſerves, (177, 234.) that when we ſay the demiſe of the crown, we mean only that in conſequence of the diſunion of the king's natural body from his body politic, the kingdom is transferred or demiſed to his ſucceſſor; and ſo the royal dignity remains perpetual. The demiſe of the king does not diſcontinue any writ or proceſs. Vide ſtat. 1 Ed. VI. cap. 7. ſect. 1, 2, 3.

Nor does it determine any commiſſion civil or military, or great office of ſtate, but they ſhall continue in force for ſix months after the ſovereign's demiſe, unleſs made void by the next ſucceſſor. Stat. 7 and 8 Will. III. cap. 27. ſect. 21. 1 Ann. ſtat. 1. cap. 8. 6 Ann. cap. 7. ſect. 8.

Neither is a parliament thereby determined till after ſix months. 7 & 8 Will. III. cap. 15.

Nor is a defendant, who hath pleaded to an information, obliged to plead to it again. But he may plead again upon requeſt made to the court, within five months after the demiſe. 4 & 5 Will. & Mar. cap. 18. ſect. 7.

Demise, and *Redemiſe*, denote a conveyance where there are mutual leaſes made from one to another of the ſame land, or ſomething out of it.

Demi-*Vills*. See Vill.

DEMIURGE, Δημιεργος, from δημιος, which denotes a *public ſervant*, and εργον, *work*, in the *Mythology of the Eaſtern Philoſophers*, was one of the Æons, employed by the ſupreme Deity in the creation of the world. The character they give him is a compound of ſhining qualities, and inſupportable arrogance; and his exceſſive luſt of empire effaces his talents and virtues. He is repreſented as claiming dominion over the new world he has formed, as his ſovereign right; and, excluding totally the ſupreme Deity from all concernment in it, he demands from mankind, for himſelf and his aſſociates, divine honours.

DEMM, in *Geography*, a town of Arabia, in the country of Yemen; 20 miles S.S.W. of Chamir.

DEMMIN, anciently called *Timin*, *Dymin*, *Demyn*, or *Dimmin*, a ſmall town of Pruſſia, in Pomerania, on the river Peene at the confluence of two lakes, the Trebel and the Tollen, with a good corn trade. It is one of the oldeſt towns in Pomerania, and greatly decayed. Several ſkirmiſhes took place in its neighbourhood between the Swedes and French in the autumn of the year 1807. It is only 36 miles S. of Stralſund.

DEMOCEDES, in *Biography*, the ſon of Calliphon of Croton, a city in Italy, acquired great fame for his ſkill in medicine and ſurgery, and ſettling at Ægina, whither he went to eſcape the tyranny of his father, he received from the city a ſalary of a talent annually. At Athens, to which place he was invited, he was engaged on a ſtipend of 100 minæ, and from Polycrates, the tyrant of Samos, to whom he was afterwards attached, he received annually two talents. From this ſtate of affluence and conſideration, he fell into the deepeſt diſtreſs. Polycrates being treacherouſly murdered by Orætes, and Orætes in his turn, killed by order of Darius Hyſtaſpis the king of Perſia, Democedes, with the reſt of the houſehold of the tyrant, were conveyed to Suſa, loaded with chains, and thrown into a dungeon. But Darius having diſlocated his ankle, and obtaining no relief from his ſurgeon, commanded Democedes to be releaſed, and to be brought before him. Under his care, the king was ſoon relieved from his pain, and the other conſequences of the accident. This brought him into great favour, which was further increaſed by his curing an ulcer in the breaſt, with which Atoſſa, the daughter of Cyrus, was afflicted. He was now lodged in a magnificent houſe, admitted to the table, and to the moſt intimate familiarity with the king, and loaded with preſents. In this ſtate he is ſaid to have employed his intereſt in procuring the pardon of his brethren, who had failed in relieving the king, who were to have been impaled. That he ſhould wiſh to eſcape from a country where favour was accorded, rather to his ſucceſs than to his ſkill, where he had ſuffered ſo much, and where he was ſtill a priſoner, will excite no ſurpriſe; accordingly his thoughts were turned in deviſing means by which he might get to his own country, which at length he effected. For pretending to enter into the views and intereſts of the Perſians, he procured himſelf to be ſent with ſome of the nobles, to explore the coaſt of Greece, and diſcover in what parts it might be attacked with the greateſt probability of ſucceſs. Stopping at Tarentum, the Perſians were ſeized as ſpies, but Democedes eſcaped to Croton, whither the Perſians, on being liberated, followed him, and demanded that he ſhould be given up to them, and on the Crotonians refuſing, they threatened them with the vengeance of the king. Democedes is ſaid to have married a daughter of the famed Milo, who was alſo a native of Croton, and to have continued there the remainder of his days. General Biography.

DEMOCRACY, formed of the Greek δημος, *people*, and κρατειν, *to command, govern*, a form of government, or conſtitution of a ſtate, by virtue of which the ſovereignty, or ſupreme authority, is lodged in the people, who exerciſe the ſame by perſons of their own order, deputed for that purpoſe. In a democracy, therefore, the people are in ſome reſpects the ſovereign, and in others the ſubject. In this kind of government, the people in whom the ſupreme power reſides, ought to do of themſelves whatever they conveniently can; and what they cannot well do, they muſt commit to the management of miniſters; but it is a fundamental maxim in a democracy, that the people ſhould chuſe their miniſters, that is, their magiſtrates, whether the election be made by themſelves, as at Athens, or by ſome magiſtrate deputed for that purpoſe, as was cuſtomary at Rome upon certain occaſions. The people, ſays Monteſquieu (Sp. of Laws, vol. i. p. 13.) are extremely well qualified for chuſing thoſe, whom they are to intruſt with part of their authority. They can tell when a perſon has been often in battle, and has had particular ſucceſs; they are therefore very capable of electing a general. They can tell when a judge is aſſiduous in his office, when he gives general ſatisfaction, and has never been charged with bribery; this is ſufficient for chuſing a prætor. They are ſtruck with the magnificence or riches of a fellow-citizen: this is as much as is requiſite for electing an ædile. But are

the

the people able to manage an affair, to find out and to make a proper uſe of places, occaſions, moments? No; this is beyond their capacity. Should we doubt of the people's natural ability in reſpect to the diſcernment of merit, we need only caſt our eyes on the continual ſeries of ſurpriſing elections made by the Athenians and Romans; which no one will ſurely attribute to hazard. As moſt citizens, though they have a capacity of chuſing, are not, however, ſufficiently qualified to be choſen; ſo the common people, though capable of calling others to an account for their adminiſtration, are incapable of the adminiſtration themſelves. The public buſineſs muſt, however, be carried on, with a certain motion neither too quick nor too ſlow. But the action of the common people is always either too remiſs or too violent. In a popular ſtate the inhabitants are divided into certain claſſes. In the manner of making this diviſion great legiſlators have ſignalized themſelves; and on this the duration and proſperity of democracy have always depended. As the diviſion of thoſe who have a right of ſuffrage is a fundamental law in a republic; ſo the manner of giving this ſuffrage is another fundamental law. The ſuffrage by lot is natural to democracy; as that by choice is to ariſtocracy. The former is a method of electing that offends no one; it allows each citizen to entertain reaſonable hopes of ſerving his country; but as this method is naturally defective, it has been the glorious endeavour of the moſt eminent legiſlators to regulate and amend it. The law which determines the manner of giving the ſuffrages is likewiſe fundamental in a democracy. The people's ſuffrages ought, without doubt, ſays Monteſquieu, to be public; and this ſhould be conſidered as a fundamental law of democracy. The lower ſort of people ought to be directed by thoſe of higher rank, and reſtrained within bounds by the gravity of certain perſonages. Hence by rendering the ſuffrages ſecret in the Roman republic all was loſt: it was no longer poſſible to direct a populace that ſought its own deſtruction. It is likewiſe a fundamental law in democracies, that the people ſhould have the ſole power to enact laws; and yet there are a thouſand occaſions in which it is neceſſary the ſenate ſhould have a power of decreeing; and it is often proper to make ſome trial of a law before it is eſtabliſhed. In this reſpect the conſtitutions of Rome and Athens were extremely wiſe. The decrees of the ſenate had the force of laws for the ſpace of a year, and did not become perpetual till they were ratified by the conſent of the people.

The principle of democracy is virtue. When Sylla wanted to reſtore Rome to its liberty, this unhappy city was incapable of receiving it. She had only ſome feeble remains of virtue, and as this was every day diminiſhing, inſtead of being rouſed out of her lethargy, by Cæſar, Tiberius, Caius, Claudius, Nero, Domitian, ſhe every day rivetted her chains; the blows ſhe ſtruck were levelled againſt the tyrants, but not at the tyranny. The politic Greeks, who lived under a popular government, knew no other ſupport but virtue. The modern inhabitants of that country are entirely taken up with manufactures, commerce, finances, riches, and luxury. The principle of democracy is corrupted, not only when the ſpirit of equality is extinct, but likewiſe when they indulge a ſpirit of extreme equality, and when every citizen wants to be upon a level with thoſe he has choſen to command him. Thus the people, incapable of bearing the very power they have intruſted, want to do every thing of themſelves, to debate for the ſenate, to execute for the magiſtrate, and to ſtrip the judges. When this is the caſe, virtue can no longer ſubſiſt in the republic. Democracy has, therefore, two exceſſes to avoid; the ſpirit of inequality, which leads to ariſtocracy or monarchy; and the ſpirit of extreme equality, which leads to deſpotic power, as the latter is compleated by conqueſt. As diſtant as heaven is from earth, ſo is the true ſpirit of equality from that of extreme equality. The former does not conſiſt in managing; ſo that every body ſhould command, or that no one ſhould be commanded; but in obeying and commanding our equals. It endeavours not to be without a maſter, but that its maſters ſhould be none but its equals. In the ſtate of nature, indeed, all men are born equal; but they cannot continue in this equality. Society makes them loſe it, and they recover it only by means of the laws. Such is the difference between a well and an ill policed democracy, that in the former men are equal only as citizens, but in the latter they are equal alſo as magiſtrates, ſenators, judges, fathers, huſbands, maſters. The natural place of virtue is near to liberty; but it is not nearer to extreme liberty than to ſervitude.

The moſt flouriſhing democracies in eminent times were thoſe of Rome and Athens, and in latter days, the republic of Geneva in Switzerland: the modern republics, as Venice, and the United Provinces, were rather ariſtocracies than democracies.

In a democracy, where the right of making laws reſides in the people at large, public virtue, or goodneſs of intention, is more likely to be found than either of the other qualities of government; and therefore it uſually poſſeſſes a conſiderable degree of patriotiſm and public ſpirit. Democracies are uſually the beſt calculated to direct the end of a law; ariſtocracies to invent the means by which that end ſhall be obtained; and monarchies to carry thoſe means into execution. See REPUBLIC.

DEMOCRAT, in *Geography*, a town of Egypt; 20 miles N. of Aſna.

DEMOCRITUS, in *Biography*, a celebrated philoſopher of the Eleatic ſect, was born at Abdera, a town of Thrace, in the firſt year of the 80th Olympiad, B. C. 460, and was contemporary with Socrates, Anaxagoras, Archelaus, Parmenides, Zeno, and Protagoras. His father was a perſon of rank and opulence, and is ſaid to have contributed liberally towards the entertainment of the army of Xerxes, on his return to Aſia, in recompence of which ſervice the Perſian king made the Abderites rich preſents, and left among them ſeveral Chaldæan magi. By theſe magi Democritus was inſtructed in aſtronomy and theology. Upon his father's death, he received the portion of 100 talents bequeathed him, and thus amply provided with money, he travelled into diſtant countries in purſuit of knowledge; firſt viſiting Egypt for the purpoſe of learning geometry of the Egyptian prieſts; then directing his courſe to Ethiopia, in order to converſe with the gymnoſophiſts of that country; and from thence he paſſed over into Aſia, where he reſided for ſome time among the Perſian magi, and, as ſome have ſaid, his curioſity led him into India. He was alſo inſtructed in the doctrines of the Pythagorean ſchool, and became a diſciple of Leucippus. His reſources were completely exhauſted in his travels, and returning deſtitute to his native place, he was amply ſupplied by his brother Damaſis. As it was a law at Abdera, that any perſon, who waſted his patrimony, ſhould be deprived of the rites of ſepulture, Democritus, dreading this diſgrace, enriched himſelf by delivering lectures to the people, out of one of the moſt valuable of his writings, entitled "Deacoſmus," ſo that he had no apprehenſion of ſuffering cenſure as a ſpendthrift. Beſides money, he acquired great fame, and excited much admiration among the ignorant Abderites. Of his knowledge of natural philoſophy, he artfully availed himſelf for predicting unexpected changes in the weather, ſo that his fellow-citizens conceived that he

poſſeſſed the faculty of predicting future events; and thus deluded they diſtinguiſhed him by the appellation of "Wiſdom," regarded him as a being more than mortal, and entruſted him with the direction of their public affairs. Preferring, however, a contemplative and ſtudious to a political and active life, he declined the public honours aſſigned him, and ſpent the reſidue of his days in ſolitude. Many marvellous tales are related concerning him during his retreat from the world; but as they are fabulous, it is needleſs to recite them. We may, nevertheleſs, deduce this inference from them, that Democritus was a man of ſublime genius and penetrating judgment; who, by much obſervation and ſtudy, and long experience, became an eminent maſter of ſpeculative and phyſical ſcience; and, like Roger Bacon at a later period, he aſtoniſhed and impoſed upon his ignorant and credulous countrymen.

Democritus has been commonly known under the appellation of the "Laughing Philoſopher;" and Seneca relates, that whenever he appeared in public, he expreſſed his contempt of the follies of mankind by laughter. But this is one of thoſe numerous tales, the truth of which is contradicted by his love of ſolitude and contemplation, and by his known character for that ſtrength and elevation of mind, which his philoſophical reſearches required. It is not improbable, however, that a man, ſo ſuperior to his ſtupid countrymen, might frequently treat their follies with ridicule and contempt. Hence, among his fellow-citizens, he obtained the appellation of γελασινος, or the "Derider." In his manners Democritus was chaſte and temperate, and his ſobriety was recompenſed by continued health and vigour in very advanced age. He is ſaid to have lived to the year B. C. 361, and to have died in his 99th year by mere decay. His death was much lamented by his countrymen, and the charge of his funeral was defrayed out of the public treaſury. He wrote much, but none of his works are extant. Diogenes Laertius has given a long catalogue of his works on natural and moral philoſophy, criticiſm, and polite literature.

Concerning truth, Democritus taught, that there are two kinds of knowledge, one obſcure, derived from the ſenſes, and another genuine, obtained by the exerciſe of thought upon the nature of things. This latter mode of acquiring certain knowledge he confeſſed to be very difficult; and, therefore, he uſed to ſay, that truth lay in a deep well, from which it is the office of reaſon to draw it up. Concerning phyſics, it was the doctrine of this philoſopher, that nothing can ever be produced from that which has no exiſtence, and that any thing which exiſts can never be annihilated. Whatever exiſts muſt conſequently owe its being to neceſſary and ſelf-exiſtent principles, of which he conceived there were two; *viz.* atoms, and a vacuum, both infinite, the former in number, the latter in magnitude. Atoms are ſolid, and the only beings; vacuum, or entire ſpace, can neither be ſaid to be exiſtent nor non-exiſtent, being neither corporeal nor incorporeal. Atoms have the property of figure, magnitude, motion, and weight, being heavy in proportion to their bulk. They are various in figure and in magnitude; and are perfectly ſolid, indiviſible, and unalterable. Theſe atoms have been eternally moving in infinite vacuum or ſpace, in a direction perpetually deviating from a right line; and thus colliſions are produced, which occaſion innumerable combinations of particles, from which ariſes the various form of things that exiſt. Theſe primary corpuſcles are moved and united by that natural neceſſity, which is the only fate that creates and governs the world. The ſyſtem of nature is one, conſiſting of parts, differing in their figure, order, and ſituation. The production of an organized body is occaſioned by the ſuitable arrangement of atoms, adapted in their nature to form that body; if it be diverſified, alteration takes place; if it be entirely deſtroyed, diſſolution. The qualities of bodies are not eſſential to their nature, but the caſual effect of arrangement; and this occaſions the different impreſſions which they make upon the ſenſes. In infinite ſpace there are innumerable worlds, ſome ſimilar, others diſſimilar; but all ſubject to growth, decay, and deſtruction. The world has no animating principle, but all things are moved by the rapid agitation of atoms. The ſun and moon are compoſed of light particles, revolving about a common centre. The heavenly bodies are arranged in the following order; firſt, the fixed ſtars, then the planets, then the ſun, then the moon: all move from eaſt to weſt, and thoſe which are neareſt revolve with the leaſt velocity; ſo that the ſun, the inferior planets, and the moon, move more ſlowly than the reſt.

A comet is a combination of planets, which approaching near each other, appear as one body. The earth at firſt was ſo ſmall and light, as to wander about in the regions of ſpace; but at length increaſing in denſity, it became immoveable. The ſea is continually decreaſing, and will at length be dried up. Man was at firſt produced from water and earth. Our knowledge of his exiſtence ariſes from conſciouſneſs. The ſoul, or principle of animal life and motion, is the reſult of a combination of round or fiery particles, conſiſting of two parts, one ſeated in the breaſt, which is the rational, the other diffuſed through the whole body, which is the irrational. The ſoul periſhes with the body; but human bodies, though they periſh, will revive. Different animal beings poſſeſs different ſenſes. Perception is produced by εἴδωλα, images, which flow from bodies according to their reſpective figures, and ſtrike upon the organ of ſenſe.

The fundamental difference between the doctrine of Democritus, and that of former philoſophers, concerning atoms, is, that the latter conceived ſmall particles endued with various qualities; whereas this philoſopher conceived the qualities of bodies to be, as we have already ſaid, the mere effect of arrangement. Democritus, in his whole ſyſtem, pays no regard to an external efficient cauſe, but abſurdly ſuppoſes, that the intrinſic neceſſity, which gives motion to atoms, is *alone* ſufficient to account for the phenomena of nature. Whatever he is ſaid to have taught concerning nature, fate, or providence, he merely aſſerted, that the fire, which reſulted from the combination of certain ſubtle atoms, and which has been called the ſoul of the world, is a mechanical agent in nature, cauſing by its rapid motion the changes which take place in the univerſe. Plutarch ſays, that Democritus conſidered the ſun and moon as ignited plates of ſtone; but this is not conſiſtent with his general ſyſtem, and with his knowledge of nature. The belief of the materiality of the ſoul was the natural reſult of the atomic ſyſtem; for if the ſoul be a mere compoſition of atoms, when theſe are diſperſed, it muſt periſh. As to the reviviſcence of human bodies, he can only be ſuppoſed to mean, that the atoms compoſing any human ſoul, would, after their diſperſion, coaleſce again, in ſome diſtant period, and recover their former life. The term εἴδωλον, or image, ſeems to have had, in his uſe of it, two different ſignifications: it denoted thoſe images which he ſuppoſed to flow from external objects, and ſtriking upon the ſenſes, excite ideas in the mind, and alſo, thoſe divine beings that exiſted in the air, and which he called gods. Although Democritus rejected the notion of Deity, and allowed him no ſhare in the creation or government of the world, he endeavoured to conceal his impiety, by admitting the popular belief of divinities inhabiting the aerial

nerial regions, and teaching that they make themſelves viſible to ſome favoured mortals, and enable them to predict future events.

The moral doctrine of Democritus, like that of Epicurus, makes the enjoyment of a tranquil ſtate of mind, εὐθυμία, the great end of life, and conſequently teaches moderation as the firſt law of wiſdom. Moreover, he maintained that there is nothing naturally becoming or baſe in human actions, but that every diſtinction of this nature ariſes from cuſtom or civil inſtitutions, and that laws are framed to reſtrain the natural propenſity of mankind to injure one another; in this latter reſpect his opinion ſeems to have coincided with the more modern doctrine of Hobbes.

We cannot forbear, before cloſing this article, to ſubjoin ſome valuable maxims of practical judgment and conduct, aſcribed to Democritus.

"He who ſubdues his paſſions is more heroic than he who vanquiſhes an enemy; yet there are men who, whilſt they command nations, are ſlaves to pleaſure. It is criminal, not only to do miſchief, but to wiſh it. He who enjoys what he has, without regretting the want of what he has not, is a happy man. The ſweeteſt things become the moſt bitter by exceſs. Do nothing ſhameful though you are alone; revere yourſelf more than all other men. A man muſt either be good or ſeem to be ſo. Every country is open to a wiſe man, for he is a citizen of the world. It is better for fools to be governed than to govern. Rulers are choſen, not to do ill, but good. By deſiring little, a poor man makes himſelf rich. A cheerful man is happy, though he poſſeſſes little; a fretful man is unhappy in the midſt of affluence. One great difference between a wiſe man and a fool is, that the former only wiſhes for what he may poſſibly obtain, the latter deſires impoſſibilities. It is the office of prudence, where it is poſſible, to prevent injuries; but where this cannot be done, a wiſe regard to our own tranquillity will preſerve us from revenging them." Diog. Laert. l. i. ix. Stob. Serm. Suidas. Sext. Emp. Plutarch. Bayle. Moreri. Brucker's Hiſt. Phil. by Enfield, vol. i. See Atomical *Philoſophy*.

Democritus, a Greek writer on muſic, of which nothing remains but the name.

DEMODOCUS, an ancient Greek bard; whoſe character Homer, as a poet, in the 7th book of the Odyſſey, exalts to the ſummit of human excellence.

DEMOGORGON, in *Mythology*, the chief of the terreſtrial divinities, as its name, derived from Δαίμων and γοργων, imports. Boccace, in his genealogy of the gods (l. 1.) repreſents him as a ſlovenly old man, overſpread with filth, pale, and diſfigured, who had his dwelling in the heart of the earth. His companions were Eternity and Chaos: growing weary, it is ſaid, of this diſmal ſolitude, he made a little bowl to ſit upon, and having raiſed himſelf into the air, encompaſſed the earth, and ſo formed the heavens. Having accidentally paſſed over the Acroceraunian mountains, he fetched from thence the burning matter, which he ſent to heaven to enlighten the world, and thus formed the ſun, which he gave in marriage to the earth; from which marriage proceeded Tartarus, the Night, &c. Demogorgon is reported to have ſeveral children, of whom the firſt was "jarring Diſcord," ſevered from the bowels of Chaos, and raiſed from the bottom of the earth to dwell upon the ſurface; Pan, his ſecond ſon, and the three Parcæ, *viz.* Clotho, Lacheſis, and Atropos, Heaven, Pitho, and the Earth, who was his eighth child. The Earth had afterwards ſeveral children, whoſe father was not known, ſuch as Night, Tartarus, Pharca, Tages, and Antæus. The ninth of Demogorgon's children was Erebus, who had a numerous offſpring. Theſe fables are ſuppoſed to allude in a myſterious manner to the creation of the world, the knowledge of which had been acquired from ſome imperfect tradition. The Arcadians, as Bauier ſuggeſts, (Mythology, &c. vol. ii. p. 550.), ſeeing that the earth of itſelf produced flowers and fruits, fountains, ſtreams, and rivers, that it frequently emitted fire and flames, and that it was liable to convulſions, imagined that ſhe was animated, and gave the name of Demogorgon to the divinity that preſided over her. The philoſophers, it is probable, meant no more by this divinity than that vegetative principle which gives life to the plants, deſcribed by Virgil, (Georg. l. ii.)

> "Spiritus intus alit, totamque infuſa per artus
> Mens agitat molem."

The vulgar fancied there was a real god, who reſided in the bowels of the earth, to whom they offered ſacrifices, eſpecially in Arcadia. Some authors, however, have imagined, that Demogorgon had been a magician, ſo ſkilful in his art, that he had ghoſts and aerial ſpirits under his command, whom he abſolutely ſubjected to his will, ſeverely puniſhing ſuch as did not execute his orders.

DEMOISELLE, the *dancing-bird*, in *Ornithology*, a long-legged and long-necked bird of the *Ardea* kind, a native of Numidia. It is remarkable for its jumping or dancing in its walk. It has the ſame kind of plication in the windpipe with the common crane. It is the Ardea *Virgo* of Gmelin, the Numidian crane of Albinus, the demoiſelle of Numidia of Edwards, and the demoiſelle of Latham. It inhabits the eaſtern and weſtern ſhores of Africa, Egypt, Numidia, Tripoli, about the Caſpian and Black ſeas, and the lake Baikal.

Its bill is yellowiſh, greeniſh at the baſe, and red at the vertex; the irides are red, the crown cinereous, the reſt black, as are alſo the neck, throat, breaſt, legs, and wings; the long feathers of the breaſt are pendulous, the creſt white and hanging backwards; the back, vent, tail, abdomen, blueiſh-cinereous.

DEMON. See Dæmon.

DEMONA, *Valley of*, in *Geography*, a diſtrict of the iſland of Sicily, lying to the north-eaſt part of the iſland, neareſt to Italy, about 100 miles long, and 20 broad.

DEMONAX, in *Biography*, a Cynic philoſopher, who flouriſhed during the reign of Adrian. He was a native of Cyprus, and deſcended from a family of wealth and high rank; but preferring a life of philoſophic ſtudy to the employments which his birth and fortune might have commanded, he removed to Athens while he was young, and there ſpent the remainder of his days. In his manners and habits he was, in ſome reſpects, the imitator of Diogenes, and hence he obtained a rank among the Cynics, though he never profeſſed himſelf to be of any ſect. From them all he ſelected what was excellent, and moſt favourable to moral wiſdom; and like Socrates he endeavoured to make philoſophy not a ſpeculative ſcience, but the rule of life and manners. He was virtuous without oſtentation, and was able to reprove vice without acrimony, and with the happieſt effect. So high was his reputation, that the greateſt deference was paid to his opinion in the aſſemblies of the Athenian people. After his death, which was not till he had attained the age of 100, he was honoured with a public funeral, attended with a numerous train of philoſophers, and others who lamented the loſs of ſo eſtimable a character. Moreri. Brucker's Hiſt. Phil. by Enfield.

DEMONIAC. See Dæmoniac.

DEMONIACAL Possession. See Dæmoniacal *Poſſeſſion*.

DEMOIVRE, Abraham, in *Biography*, a celebrated

mathematician, born at Vitri, in France, in the year 1667. At the revocation of the edict of Nantz, in 1685, he determined, with many others, to take ſhelter in England, where he purſued the mathematics with great eagerneſs, having laid the foundation of this knowledge in his own country. His very limited income induced him to give leſſons to private pupils, and alſo to read public lectures on the branches of ſcience in which he was moſt converſant. Sir Iſaac Newton's "Principia" falling in his way, led him to pay particular attention to geometrical inveſtigations, and he ſhortly after became a firſt rate mathematician. He was ſoon aſſociated with the principal philoſophers of his own times, and was elected member of the Royal Society of London, and alſo of the academies of Berlin and Paris. By the former he was fixed on as a fit perſon to decide the famous conteſt between Newton and Leibnitz concerning the invention of fluxions. Towards the cloſe of his life he was conſulted on all queſtions relating to chances, gaming, and annuities, and by his anſwers he chiefly ſubſiſted. He died at London November 1754, at the great age of 87 years. Beſides many important and intereſting papers in ten or twelve volumes of the Philoſophical Tranſactions of London, he publiſhed, 1. "Miſcellanea Analytica de Seriebus et Quadraturis," &c. 2. A 4to volume on the "Doctrine of Chances;" and another volume in 8vo. "On Annuities." This was firſt printed in the year 1724. A few years afterwards, Mr. Thomas Simpſon publiſhed a work on the ſame ſubject, in which he paid ſome handſome compliments to Demoivre, who ſo far from feeling the obligation, paſſed ſeveral ſevere and unmerited cenſures on Mr. Simpſon in a ſecond edition of his own work. Mr. Simpſon replied, and here the controverſy terminated, but by no means to the credit of M. Demoivre, who was conſidered by the philoſophers of that day as having acted in an uncandid and ungracious manner towards a young man of high merit and extraordinary talents.

DEMONIUS LAPIS, in *Natural Hiſtory*, a name given to a ſtone famous among the writers of the middle ages for a number of imaginary virtues, ſuch as rendering people victorious over their enemies, and the like. All the deſcription they have left us of it is, that it was variegated with two colours laid in lines ſo as to repreſent a rainbow. It was probably an agate.

DEMONSTRABLE, a term uſed in the ſchools, to ſignify ſomewhat that may be clearly and evidently proved: thus, it is demonſtrable that the ſide of a ſquare is incommenſurable with the diagonal.

DEMONSTRATION, in *Logic*, a ſyllogiſm in form, containing a clear and irrefragable proof of the truth of a propoſition.

A demonſtration is a convincing argument, the two firſt propoſitions whereof are certain, clear, and evident; whence of neceſſity ariſes an infallible concluſion.

A demonſtration uſually conſiſts of three parts; explication, preparation, and concluſion.

The explication is the laying down of the things ſuppoſed to be given or granted; from which the demonſtration is to be made. The preparation is ſomething to be previouſly done, according to the nature of the demonſtration intended. The concluſion is a propoſition that concludes the thing to be demonſtrated, fully perſuading, and convincing the mind.

The method of demonſtrating things in mathematics is the ſame with that of drawing concluſions from principles in logic. In effect, the demonſtrations of mathematicians are no other than ſeries of enthymemes: every thing is concluded by force of ſyllogiſm, only omitting the premiſes, which either occur of their own accord, or are recollected by means of quotations. To have the demonſtration perfect, the premiſes of the ſyllogiſms ſhould be proved by new ſyllogiſms, till at length you arrive at a ſyllogiſm, wherein the premiſes are either definitions, or identic propoſitions.

Indeed it might be demonſtrated, that there cannot be a genuine demonſtration, *i. e.* ſuch a one as ſhall give full conviction, unleſs the thoughts be directed therein according to the rules of ſyllogiſm. Clavius, it is well known, reſolved the demonſtration of the firſt propoſition of Euclid into ſyllogiſm: Herlinus, and Daſipodius, demonſtrated the whole ſix firſt books of Euclid, and Heniſchus, all arithmetic, in the ſyllogiſtic form.

Yet people, and even mathematicians, uſually imagine, that mathematical demonſtrations are conducted in a manner far remote from the laws of ſyllogiſm; ſo far are they from allowing that thoſe derive all their force and conviction from theſe. But we have men of the firſt rank on our ſide the queſtion. M. Leibnitz, for inſtance, declares that demonſtration to be firm and valid, which is in the form preſcribed by logic; and Dr. Wallis confeſſes, that what is propoſed to be proved in mathematics, is deduced by means of one, or more ſyllogiſms: the great Huygens, too, obobſerves, that paralogiſms frequently happen in mathematics, through want of obſerving the ſyllogiſtic form. See SYLLOGISM.

Problems conſiſt of three parts: a propoſition, reſolution, and demonſtration.

In the propoſition is indicated the thing to be done.

In the reſolution, the ſeveral ſteps are orderly rehearſed, whereby the thing propoſed is performed.

Laſtly, in the demonſtration it is ſhewn, that the things enjoined by the reſolution being done, that which was required in the propoſition is effected. As often, therefore, as a problem is to be demonſtrated, it is converted into a theorem; the reſolution being the hypotheſis, and the propoſition the theſis: for the general tenor of all problems to be demonſtrated is this; that the thing preſcribed in the reſolution being performed, the thing required is done.

The ſchoolmen make two kinds of demonſtration; the one τὸ διοτι, or *propter quod*; wherein an effect is proved by the next cauſe. As when it is proved, that the moon is eclipſed, becauſe the earth is then between the ſun and moon. The ſecond τὸ ὅτι, or *quia*; wherein the cauſe is proved from a remote effect: as when it is proved, that fire is hot, becauſe it burns; or that plants do not breathe, becauſe they are not animals; or that there is a God, from the works of creation. The former is called demonſtration à priori, and the latter demonſtration à poſteriori.

DEMONSTRATION, *Affirmative*, is that which, proceeding by affirmative and evident propoſitions, dependent on each other, ends in the thing to be demonſtrated.

DEMONSTRATION, *Apagogical*. See APAGOGICAL.

DEMONSTRATION, *Geometrical*, is that framed of reaſonings drawn from the elements of geometry.

DEMONSTRATION, *Mechanical*, is that, the reaſonings whereof are drawn from the rules of mechanics.

DEMONSTRATION *à priori*, is that whereby an effect is proved from a cauſe, either a next, or remote one; or a concluſion proved by ſomething previous, whether it be a cauſe, or only an antecedent.

DEMONSTRATION *à poſteriori*, is that whereby either a cauſe is proved from an effect, or a concluſion is proved by ſomething poſterior; whether it be an effect, or only a conſequent.

DEMONSTRATIVE, in *Rhetoric*, one of the genera, or

or kinds, of eloquence; being that which obtains in the compoſing of panegyrics, invectives, gratulatory and funeral orations.

Rhetoric is divided into three kinds; deliberative, demonſtrative, and judiciary. See RHETORIC.

Demonſtrative diſcourſes, conſiſt either in praiſe or diſpraiſe; and theſe reſpect either perſons or things. In praiſing or diſpraiſing perſons, rhetoricians preſcribe two methods. One is, to follow the order, in which every thing happened, that is mentioned in the diſcourſe; and the other is, to reduce what is ſaid under certain general heads, without a ſtrict regard to the order of time. In the proſecution of the firſt method, the diſcourſe may be conveniently divided into three periods; the firſt containing occurrences that preceded the perſon's birth; the ſecond the whole courſe of his life; and the third events ſubſequent to his death. Under the firſt of theſe may be comprehended what is proper to be ſaid concerning his country or family; under the ſecond the qualities of his mind and body, together with his circumſtances in the world; and under the third, the public loſs, and public honours conferred upon the deceaſed. This order of time has been followed by Iſocrates, in his funeral oration upon Evagoras, king of Salamis, and by Pliny, in his panegyric upon the emperor Trajan. This kind of diſcourſe, in which the method is plain and obvious, will require the more agreeable arts to render it intereſting and delightful; but otherwiſe it ſeems rather like an hiſtory than an oration. The other method above ſuggeſted was to reduce the diſcourſe to certain general heads, without regarding the order of time. As if any one in praiſing the elder Cato, ſhould propoſe to do it by ſhewing, that he was a moſt prudent ſenator, an excellent orator, and moſt valiant general; all which commendations are given him by Pliny. (Hiſt. Nat. l. vii. c. 27.) In like manner the character of a good general may be compriſed under four heads; ſkill in military affairs, courage, authority, and ſucceſs; from all which Cicero recommends Pompey; (Pro Leg. Manil. c. 24.) and agreeably to this method Suetonius has written the lives of the firſt twelve Cæſars.

Things, as diſtinguiſhed from *perſons*, comprehend all beings inferior to man; and likewiſe the habits and diſpoſitions of men, either good or bad, when conſidered ſeparately and apart from their ſubjects, as arts and ſciences, virtues and vices; with whatever elſe may be a proper ſubject for praiſe or diſpraiſe. In diſcourſes of this kind, whether of praiſe or diſpraiſe, the orator ſhould well conſider where, and to whom he ſpeaks, and adapt his diſcourſe to his audience. Ward's Oratory, vol. i. lect. 7.

DEMONSTRATIVE, in *Grammar*, is applied to pronouns which ſerve to ſhew, point out, or indicate a thing: as, *this*, *that*, *thoſe*, &c.

They are alſo called definitive, becauſe they define and limit the extent of the common name, or general term, to which they either refer, or are joined.

DEMONSTRATIVE *Evidence*. See DEDUCTIVE, and EVIDENCE.

DEMONT, or DEMONTE, in *Geography*, a town of France, in the department of the Sture, which formerly was a part of Piedmont in Italy, with a caſtle on the river Sture, and a population of 6000 individuals; 12 miles S.W. of Coni. N. lat. 44° 19′. It is the chief place of a canton in the diſtrict of Coni. The canton has 5 communes, and 9249 inhabitants.

DEMOSTHENES, in *Biography*, the moſt celebrated orator of ancient Greece, was the ſon of a reſpectable citizen of Athens, who was the proprietor of large iron-forges, and kept a number of ſlaves manufacturing ſword-blades, and furniture of different kinds, by which he acquired conſiderable wealth; though Juvenal (l iv. ſat. 10.) has unjuſtly degraded his origin. He was born in the fourth year of the 99th olympiad, B.C. 381; and at the age of ſeven years he loſt his father, who left him a patrimony of 14 talents, (about 3150*l.* ſterling.) Being of a feeble conſtitution and delicate health, his fond mother would not allow him to be enured to any laborious exerciſe, and by the unfaithfulneſs of his guardians, he was deprived of the means of procuring thoſe advantages in literary tuition to which his fortune entitled him. In his 17th year he determined to devote himſelf to the bar, his ambition being excited, as ſome ſay, by hearing the public pleadings in an important cauſe; others ſay, that at this age he pleaded his own cauſe, againſt his fraudulent guardians with ſucceſs. However this be, he aſſiduouſly applied to ſtudy the art of declamation; and with this view he frequented the ſchool of Iſæus, either becauſe the terms of Iſocrates were too high for his finances, or perhaps, becauſe he preferred the energy and vehemence of the former to the more mild and gentle eloquence of the latter, whoſe ſchool was at this time the moſt famous at Athens. At the ſame time he was an auditor of Plato, and diligently ſtudied his works; to which circumſtance he was indebted in a great degree for the magnificence of his diction. He laboured, however, under ſeveral natural infirmities and defects, which were likely to impede his progreſs in his profeſſion, and which he was therefore determined to overcome. His voice was weak and ſtammering, his pronunciation indiſtinct, and his geſture ungraceful. In order to ſurmount theſe diſadvantages, he ſhut himſelf up in a cave, that he might ſtudy with leſs diſtraction, and there declaimed, ſo that he could not be heard or diſturbed, and he remained in this ſubterraneous apartment for two or three months at a time. He likewiſe exerciſed his voice on the ſea-ſhore, that he might accuſtom himſelf to a tumultuous aſſembly, and in walking up hill, with pebbles in his mouth, that he might correct a defect in his utterance; he practiſed at home before a mirror, and with a naked ſword over his ſhoulders, and alſo took leſſons of an eminent actor, that he might check and reform an ungraceful motion, to which he was ſubject; and by theſe various means, ſteadily purſued, he not only overcame his defects, but acquired diſtinguiſhed excellence both in elocution and action. He alſo ſuperadded the ſtudy of language and the art of compoſition, without which no outward gracefulneſs of utterance and geſture could have enſured to him that fame, which has been tranſmitted, with his admirable orations, to after-ages. He does not appear to have excelled in extemporaneous ſpeaking, and therefore his orations were ſaid to ſmell of the lamp; nevertheleſs on ſome important occaſions he diſtinguiſhed himſelf without premeditation, or at leaſt previous compoſition. Deſpiſing the affected and florid manner of the rhetoricians of his age, he made Pericles his model, and imitated his manly and forcible eloquence, ſo that ſtrength and vehemence are the principal characteriſtics of his ſtyle. In his addreſſes to the people he aſſumes the tone of a man of virtue and patriotiſm, and whilſt he cenſures them for their follies and vices, he inculcates independence in principle, and vigour in action. In his Olynthiacs and Philippics, which are his capital orations, he had a fine field for the diſplay of his talents; the object he had in view was to rouſe the indignation of his countrymen againſt Philip of Macedon, the avowed enemy of the liberties of Greece; and to guard them againſt the inſidious meaſures by which that crafty prince endeavoured to lull them into ſecurity. In the proſecution of this, he adopts every proper method for animating a people renowned for juſtice, humanity, and valour; but in many inſtances become corrupt

rupt and degenerate. He boldly taxes them with their venality, indolence, and indifference to the public cauſe; whilſt with conſummate art, he calls to their remembrance the glory of their anceſtors, and leads them to conſider that they were ſtill a flouriſhing and powerful people, the natural protectors of the liberty of Greece, and that they only wanted the inclination to exert themſelves, in order to make Philip tremble. With his contemporary orators, who were in the intereſt of Philip, or who perſuaded the people to peace, he keeps no meaſures, but reproaches them as the betrayers of their country. Phocion was of this number; he on all occaſions oppoſed the violence of the people; and when Demoſthenes once told him that the Athenians would ſome day murder him in a mad fit, he anſwered, "And you too, perhaps, in a ſober fit." Such is the ſtrain of the orations abovementioned, which are ſtrongly animated, and abounding with the impetuoſity and fire of public ſpirit. The figures which he uſes are never ſought after, but riſe from the ſubject, and are employed ſparingly, for ſplendour and ornament do not diſtinguiſh the compoſitions of Demoſthenes. His character, as an orator, is formed by energy of thought, which is peculiar to himſelf, and elevates him above all others. Things, and not words, appear to be the objects of his attention. He has no parade and oſtentation; no methods of inſinuation; no laboured introductions; but like a man, fully poſſeſſed by his ſubject, after preparing his audience by a ſentence or two for hearing plain truths, he enters directly on buſineſs; warming the mind, and impelling to action.

When Philip had aſſembled an army for the invaſion of Attica, Demoſthenes was deputed to perſuade the Bœotians to take part againſt him; and ſuch was the force of his eloquence that he prevailed, though Python, an orator of great fame, and the advocate of Philip, exerted his efforts againſt him. At Cheronæa, however, Philip obtained a victory over the combined forces, and our orator incurred indelible reproach on the occaſion, as he deſerted his poſt, threw down his arms, and fled with ſuch precipitation, that his robe got entangled on a ſtake, and terror ſuggeſting to him that an enemy had ſeized him, he exclaimed "Spare my life!" In conſequence of this defeat, Demoſthenes was accuſed by the party that oppoſed him at Athens; but he was acquitted by the people. After the death of Philip, young Alexander was deſpiſed; and Demoſthenes thought this a favourable opportunity for cruſhing the Macedonians, and ſucceeded in obtaining a new league among the Grecian ſtates. But the vigorous proceedings of the young king diſſolved the confederacy; and Demoſthenes was one of a deputation appointed to wait upon him and divert his anger; but the courage of the orator failed him, and he turned back upon the road. Alexander required him to be delivered up among other orators; but Demades pacified the king without this ſacrifice. Demoſthenes, having diſplayed his patriotiſm by rebuilding the walls of Athens at his own expence, was recompenſed by a crown of gold, which was decreed to him. Æſchines, the orator, accuſed him on this account; and the accuſation occaſioned a ſolemn trial, and produced Demoſthenes's famous oration, "Pro Corona." He was acquitted by a great majority, and his adverſary was under a neceſſity of quitting Athens for ever. On this occaſion the two orators were competitors; but on a compariſon Æſchines is feeble and unimpreſſive, Demoſthenes is like a torrent which nothing can reſiſt. He draws the character of his antagoniſt in the ſtrongeſt colours, and all the deſcriptions in this oration are highly picturesque. There runs through it a ſtrain of magnanimity and high honour. The orator ſpeaks with that ſtrength and conſcious dignity which great actions and public ſpirit alone inſpire.

Soon after this conteſt a circumſtance occurred, which entailed diſgrace on the character of Demoſthenes. Harpalus, one of Alexander's officers, had been guilty of peculation, and made his eſcape to Athens, as a place of ſafety. Demoſthenes at firſt diſſuaded the Athenians from giving him protection; but on a ſurvey of the treaſures of Harpalus, the ſight of one of the king's golden cups corrupted his integrity. He poiſed it in his hand, and aſked its weight. Harpalus replied, "To you it ſhall weigh 20 talents;" and at night he ſent the orator the cup with that ſum. On the next day, when the caſe of Harpalus was to be conſidered, Demoſthenes appeared in the aſſembly with his throat muffled, and being called upon to ſpeak, he made ſigns that he had loſt his voice. Afterwards provoking an enquiry, as if he had been able to vindicate his innocence, he was tried, found guilty, and was ſentenced to pay a fine of 50 talents, or to be impriſoned till the money was paid; but in order to avoid diſgrace and confinement, he fled to Ægina. Some of his former adverſaries preſſed him to accept money on his departure: and when they exhorted him to bear his fate with courage and reſignation, he replied, "How can I forbear ſorrow on leaving a place where my enemies are more generous than any friends I can meet with elſewhere?" On the death of Alexander, when a new confederacy was planned by the Greek ſtates, Demoſthenes aſſiſted the Athenian deputies in their efforts for the common cauſe, and made himſelf ſo popular, that a decree paſſed for his recall: and upon his return, the whole body of citizens conducted him home in triumph. Although the fine could not be remitted, an equal ſum was granted him under the pretext of paying his charges as conductor of the ſacrifices to Jupiter the preſerver. But the victory of Antipater changed the fortune of Greece, and Athens, as the price of its pardon, was obliged to ſacrifice Demoſthenes and the orators of the ſame party. On the motion of Demades, a decree was paſſed condemning them to death. Demoſthenes took ſanctuary in the temple of Neptune at Calauria. But apprehending that attempts would be made to draw him from his place of refuge, he provided himſelf with poiſon; and when his expectations were realiſed, by an emiſſary of Antipater, he retired to the interior part of the temple, and ſwallowed the doſe. Then turning to Archias, the meſſenger of Antipater, who had been a player, he ſaid, "Now you may perform the part of Creon as ſoon as you pleaſe, and caſt out this carcaſe unburied." Then turning to the altar, he exclaimed, "O Gracious Neptune! I depart alive from thy temple without profaning it, which the Macedonians would have done by my murder." Staggering as he attempted to retire, he fell by the altar, and with a groan expired. He died at the age of 59, in the year B.C. 322. The Athenians not long after erected his ſtatue in braſs, and decreed that the eldeſt of his family ſhould be maintained at the public expence.

In his private character Demoſthenes was vindictive, auſtere, and implacable. For his vanity, his celebrity may be pleaded as an apology; but his love of money diſgraced him both in his political and profeſſional capacity. Patriotiſm was undoubtedly a diſtinguiſhing trait of his character; and it has been alleged to his honour, that Philip regarded him as the chief obſtacle to his ambitious deſigns. "In that great conteſt," ſays one of his biographers, "he ſeems to have been uniformly conſiſtent; and though his conduct on ſome occaſions wanted dignity, and on others reſolution, it was governed by ſteady principle." As an orator he is univerſally allowed to ſtand at the head of his profeſſion. Ci-

cero

cero calls him "a perfect orator," and prefers him to all other ſpeakers, Greek or Roman. Yet Cicero could only judge of him from his writings; whilſt he was a ſtranger to that *action*, which Demoſthenes reckons the firſt, the ſecond, and the third part of oratory. Quinctilian ſpeaks of him as excelling all others in what the Greeks called δεινωσις, or that kind of diction which aggravates every circumſtance proper to excite the ſtronger emotions. "Such," ſays he, "is the force, the conciſeneſs, the tone, and vigour of his language, that you can find nothing either deficient or redundant."

"The ſtyle of Demoſthenes" ſays Dr. Blair, (Lectures, vol. ii.) "is ſtrong and conciſe, though ſometimes, it muſt not be diſſembled, harſh and abrupt. His words are very expreſſive; his arrangement is firm and manly; and though far from being unmuſical, yet it ſeems difficult to find in him that ſtudied but concealed number and rhythmus, which ſome of the ancient critics are fond of attributing to him. Negligent of theſe leſſer graces, one would rather conceive him to have aimed at that ſublime which lies in ſentiment. His action and pronunciation are recorded to have been uncommonly vehement and ardent: which, from the manner of his compoſition, we are led to believe. The character which one forms of him, from reading his works, is of the auſtere, rather than the gentle kind. He is, on every occaſion, grave, ſerious, paſſionate, taking every thing in a high tone: never lets himſelf down, nor attempts any thing like pleaſantry. If any fault can be found with his admirable eloquence, it is that he ſometimes borders on the hard and dry. He may be thought to want ſmoothneſs and grace; which Dionyſius of Halicarnaſſus attributes to his imitating too cloſely the manner of Thucydides, who was his great model for ſtyle, and whoſe hiſtory he is ſaid to have written eight times over with his own hand. But theſe defects are far more than compenſated, by that admirable and maſterly force of maſculine eloquence, which, as it overpowered all who heard it, cannot, at this day, be read without emotion." However, to a modern many of the beauties of diction are loſt; but we have ſuch hiſtorical proof of the efficacy of his oratory, that it is impoſſible to doubt of its real excellence. It was Demoſthenes,

> "—— quem mirabantur Athenæ
> Torrentem, et pleni moderantem frænа theatri:
> Juvenal. Sat. x.

He was the chief of thoſe who, in Milton's words,

> "Wielded at will that fierce democrate,
> Shook th' arſenal, and fulmin'd over Greece,
> To Macedon, and Artaxerxes' throne. Parad. Reg.

On the ſubject of comparing Cicero and Demoſthenes, much has been ſaid by critical writers. The different manners of theſe two princes of eloquence, and the diſtinguiſhing characters of each, are ſo ſtrongly marked in their writings, that the compariſon is, in many reſpects, obvious and eaſy. The character of Demoſthenes is vigour and auſterity; that of Cicero is gentleneſs and inſinuation. In the one, you find more manlineſs, in the other, more ornament. The one is more harſh, but more ſpirited and cogent; the other more agreeable, but withal, looſer and weaker. To Demoſthenes it is a diſadvantage, that, beſides his conciſeneſs, which ſometimes produces obſcurity, the language in which he writes is leſs familiar to moſt of us, than the Latin, and we are leſs acquainted with the Greek antiquities than we are with the Roman. We read Cicero with more eaſe, and of courſe with greater pleaſure: and it muſt be allowed, that Cicero is in himſelf a more agreeable writer than the other. "But," ſays Dr. Blair, "I am of opinion, that were the ſtate in danger, or ſome great national intereſt at ſtake, which drew the ſerious attention of the public, an oration in the ſpirit and ſtrain of Demoſthenes, would have more weight, and produce greater effect, than one in the Ciceronian manner. Were Demoſthenes's Philippics ſpoken in a Britiſh aſſembly, in a ſimilar conjuncture of affairs, they would convince and perſuade at this day. The rapid ſtyle, the vehement reaſoning, the diſdain, anger, boldneſs, freedom, which perpetually animate them, would render their ſucceſs infallible over any modern aſſembly. I queſtion whether the ſame can be ſaid of Cicero's orations; whoſe eloquence, however beautiful, and however well ſuited to the Roman taſte, yet borders oftener on declamation, and is more remote from the manner in which we now expect to hear real buſineſs and cauſes of importance treated." In this judgment Mr. Hume concurs, in his "Eſſay upon Elocution." He gives it as his opinion, that of all human productions, the orations of Demoſthenes preſent to us the models which approach the neareſt to perfection. In comparing Demoſthenes and Cicero, the French critics, however, are diſpoſed to give the preference to the latter. One exception, however, occurs. Fenelon, the famous archbiſhop of Cambray, gives the palm to Demoſthenes.

Demoſthenes is ſaid to have compoſed 65 orations, of which a ſmall proportion only is come down to our times. Among the beſt editions of theſe are that of Frankfort, 1604, folio, with Wolfius's Latin verſion: of Taylor, unfiniſhed, 3 vols. 4to. Cantab.; and of Reiſke, 10 vols. 8vo. Leipſ. 1770. Plut. Vit. Demoſth. Cicero de Oratore et Brutus. Quinctilian Inſt. Univ. Hiſt. Gen. Biog. Rollin's Anc. Hiſt.

DEMOTICA, or Dimotuc, in *Geography*, a town of European Turkey, in the province of Romania, ſituated near the Maritſch, where a Greek archbiſhop reſides, and where the Chriſtians have two churches; 12 miles S. of Adrianople.

DEMOURS, Peter, in *Biography*, doctor in medicine, but more known as an oculiſt, was the ſon of Anthony Demours, an apothecary at Marſeilles, under whom he received the early part of his education, which was continued at Avignon, where he reſided, until he had taken the degree of doctor: this was in the year 1728. He then removed to Paris, and was placed for two years under M. Du Verney, to improve himſelf in anatomy. On the death of Du Verney, he was aſſociated with M. Chirac in the care of the cabinet of natural hiſtory, in the royal garden at Paris. Having made the ſtructure of the eye in a particular manner his ſtudy, in 1741 he ſent to the royal academy of ſciences a memoir on the ſubject, in which he ſhews that the vitreous humour is of a cellular texture, and that the cells communicate with each other, which had not been before obſerved. He now employed himſelf, almoſt excluſively, in attending to the diſeaſes of the eye, and ſoon attracted ſo much notice as to be appointed oculiſt to the king. In 1767, he publiſhed "Lettre a M. Petit," on the ſubject of a diſeaſe in the eyes, occurring in a patient who had been inoculated with the ſmall-pox. As he had acquired a competent knowledge of the Engliſh language, he tranſlated into French the Edinburgh medical eſſays, which he publiſhed at Paris, in eleven volumes, 12mo. Baker's Natural Hiſtory of the Polypus. Hales's account of a Ventilator. Ranby's treatiſe of Gunſhot Wounds, and ſeveral volumes of eſſays on medicine, and on natural hiſtory, taken from the Philoſophical Tranſactions, which procured him to be elected one of the foreign members of the royal ſociety. He had been before aſſociated with the royal academy of ſciences at Paris. De-

mours died in 1770, at an advaneed age. Eloy. Dict. Hiſt.

DEMPSTER, Thomas, in *Biography*, a Scots writer, born about the year 1579. He was educated in the Roman catholic religion, but left his native country, and ſtudied for ſome time at Pembroke hall, Cambridge. From thence he went to Paris, where he pretended that he had left a great property in his own country, through attachment to his religion. It does not appear that he obtained much credit on account of theſe aſſertions, but was obliged to keep a ſchool for his maintenance. The violence of his temper, and the muſcular powers of his body, on which he ſeemed to depend, led him into many diſputes, the event of which obliged him to take refuge in England. He brought with him a very beautiful wife, whoſe exquiſite features and form attracted uncommon notice in the ſtreets as ſhe paſſed, ſo that, we are told by Bayle, it was with difficulty ſhe could proceed. Dempſter next went to Piſa where he became a profeſſor in the univerſity; here his wife eloped with one of his ſcholars. He then removed to Bologna, where he taught with great reputation, and was admitted as member of the academy. He died in 1625. He was author of many works in law, antiquities, philology, and the ſeveral branches of the belles lettres. He wrote alſo "A Martyrology of Scotland." But his hiſtorical facts have ever been regarded with ſuſpicion. In his liſt of Scottiſh writers he has put a number of celebrated authors, who are known not to have been born there. He has been thus characterized by M. Baillet, a prieſt of his own profeſſion. He forged titles of books which were never publiſhed, to raiſe the glory of his native country, and has been guilty of ſeveral cheating tricks, by which he has loſt his credit among men of learning. "He was," ſays the learned Bayle, "a man of a prodigious memory, indefatigable, a zealous friend, and a violent enemy; he had no great judgment, nor much honeſty; for he publiſhed I know not how many fables without ſhame. Some of his books were condemned by the Inquiſition." Moreri. Bayle.

DEMULCENT Medicines, are thoſe ſubſtances which tend to obviate the irritation of acrid and ſtimulant matters in the body, not by correcting or changing their acrimony, but merely by involving it in a mild and viſcid matter, which prevents it from acting upon the ſenſible parts. This claſs of medicines compriſes the vegetable mucilages or gums, and the fixed animal and vegetable oils. The latter may be uſed for the purpoſe of covering the acrimonious qualities both of acids and alkalies; and even vitriolic acid may be in a great meaſure covered by being mixed with the mucilage of gum arabic.

Theſe effects of demulcent medicines are ſufficiently evident with reſpect to the external parts; and it may be preſumed that the ſame may happen with reſpect to the internal, ſo long as the acrid continues mixed with the demulcent. It has generally, however, been conſidered by phyſicians, till the time of Dr. Cullen, and even now the doctrine is followed in practice to a great extent, that demulcents act upon diſtant organs of the body through the medium of the circulation. Thus the gum arabic, which is the mucilage moſt univerſally employed, becauſe it can be introduced in the moſt concentrated ſtate, and therefore in the largeſt quantity, is ſuppoſed to extend its demulcent qualities to the bronchiæ, and there to correct the acrimony that occaſions coughing; and it is eſpecially ſuppoſed to reach the urinary organs, and there to cover any acrimony prevailing in the urine, and thus to relieve ſtrangury, ardor urinæ, &c.

But it is difficult to ſuppoſe that the demulcent matter retains its mild and inviſcating quality, after it has been taken into the body. For, in the firſt place, its viſcidity muſt be greatly diminiſhed in its paſſage through the ſtomach and inteſtines to the blood-veſſels, ſuppoſing that no other change took place, by mere dilution with the ſerous fluids. But, ſecondly, it is not to be queſtioned that demulcents, which are commonly of a very nutritious nature, ſhould paſs through the ſtomach, without undergoing that digeſtive proceſs, by the power of the gaſtric liquor, which all ſuch matter undergoes; *i. e.* that it ſhould, in common with other ſubſtances taken in, be altogether changed in its qualities, and rendered of the ſame fluidity with the other matters that paſs into the lacteals; in a word, that theſe demulcents can have no effect as ſuch, in the maſs of the blood, or in paſſing by the various excretions.

Beſides this general reaſoning with reſpect to mucilages, the conſideration of the quantity thrown in is of no ſmall weight. In common practice, hardly more than a few ounces are given in one day; and it is obvious that this can communicate a very ſlight mucilaginous quality to many pounds of ſeroſity. But not only reaſoning *à priori*, experience alſo coincides in proving the correctneſs of this opinion. "What others may have obſerved," ſays Dr. Cullen, "I cannot determine; but, for myſelf, I can aſſert that, in innumerable trials, I have never obſerved the effects of gum arabic in the maſs of the blood, or in the excretions derived from it. The moſt frequent occaſion for its uſe is in the ardor urinæ; and in that I have been often diſappointed, and have often found, that two pounds of water, or watery liquors, added to the drink, would be of more ſervice than four ounces of gum arabic, taken in without ſuch addition." Materia Medica, vol. ii.

In ſhort, there has been a deception, not uncommon in the practice of medicine, upon this ſubject. When the urine is much diluted, its acrid ſalts are diffuſed through a large medium, and irritate the paſſages but little. Hence the effects of the quantity of liquid containing mucilage in ſolution, have been miſtaken for the effects of the mucilage, which it contained.

In the caſe of coughing, mucilages, which often decidedly allay it, and ſuſpend the repetition of it, produce their beneficial effects not by covering the acrimony of the circulating fluids, but, by beſmearing the throat and preſerving thoſe parts from the irritation of their own ſecretions, and of the matter raiſed from the lungs.

DEMURRAGE, in *Traffic*, an allowance made to the maſter of a ſhip, by the merchants for ſtaying in a port longer than the time firſt appointed for his departure.

DEMURRER, in *Law*, a kind of pauſe, or ſtop, put to the proceeding of any action, upon ſome difficult point, which muſt be determined by the court, before any further progreſs can be had in it.

In every action, the controverſy is either as to fact, or as to law; the firſt, decided by the jury, the ſecond, by the court.

A demurrer is, therefore, an iſſue upon matter of law; and it confeſſes the facts to be true, as ſtated by the oppoſite party, but denies, that by the law ariſing upon theſe facts, any injury is done to the plaintiff, or that the defendant has made out a legitimate excuſe; accordingly the party, which firſt demurs, (*demuratur*, *moratur in lege*), reſts or abides upon the point in queſtion. As, if the matter of the plaintiff's complaint or declaration be inſufficient in law, as by not aſſigning any ſufficient treſpaſs, then the defendant demurs to the declaration; if, on the other hand, the defendant's excuſe or plea be invalid, as if he pleads that he committed the treſpaſs by authority from a ſtranger, without making out

out the ſtranger's right; here the plaintiff may demur in law to the plea:—and ſo on in every other part of the proceedings, where either ſide perceives any material objection in point of law, upon which he may reſt his caſe.

The form of ſuch demurrer is by averring the declaration or plea, the replication or rejoinder, to be inſufficient in law to maintain the action or the defence; and therefore praying judgment for want of ſufficient matter alleged. Sometimes demurrers are merely for want of ſufficient *form* in the writ or declaration. But in caſe of exceptions to the form, or manner of pleading, the party demurring muſt, by ſtatute 27 Eliz. c. 5. and 4 & 5 Ann. c. 16. ſet forth the cauſes of his demurrer, or wherein he apprehends the deficiency to conſiſt. And upon either a *general*, or ſuch a *ſpecial* demurrer, the oppoſite party muſt aver it to be ſufficient, which is called "a joinder in demurrer;" and then the parties are at iſſue in point of law; which iſſue in law, or demurrer, the judges of the court before which the action is brought muſt determine. (Finch. L. lib. iv. c. 40. 1 Inſt. 71. Blackſt. Comm. vol. iii. p. 314.)

Accordingly, demurrers, or queſtions concerning the *ſufficiency* of the matters alleged in the pleadings, are to be determined by the judges of the court, upon ſolemn argument by counſel on both ſides; and to that end a demurrer book is made up, containing all the proceedings at length, which are afterwards entered on *record*; and copies thereof, called *paper-books*, are delivered to the judges to peruſe. When the ſubſtance of the record is completed, and copies are delivered to the judges, the matter of law upon which the demurrer is grounded, is upon ſolemn argument determined by the court, and not by any trial by jury: and judgment is thereupon accordingly given.

A *demurrer in equity* is nearly of the ſame nature as a demurrer in law; being an appeal to the judgment of the court, whether the defendant ſhall be found to anſwer the plaintiff's bill; as for want of ſufficient matter of equity therein contained; or, when the plaintiff, upon his own ſhewing, appears to have no right; or where the bill ſeeks a diſcovery of a thing which may cauſe a forfeiture of any kind, or may convict a man of any criminal miſbehaviour. For any of theſe cauſes a defendant may demur to the bill. And if, on demurrer, the defendant prevails, the plaintiff's bill ſhall be diſmiſſed: if the demurrer be over-ruled, the defendant is ordered to anſwer. Bl. Comm. v. iii. p. 466.

DEMURRER *to evidence* takes place when a record, or other matter, is produced in evidence, concerning the legal conſequences of which there ariſes a doubt or queſtion in law; in which caſe the adverſe party may, if he pleaſes, demur to the whole evidence, which admits the truth of every fact that has been alleged, but denies the ſufficiency of them all in point of law to maintain or overthrow the iſſue. (Co. Litt. 72. 5 Rep. 104.) This draws the queſtion of law from the cognizance of the jury, to be decided by the court. But this kind of demurrer is now ſeldom uſed.

DEMURRER *to indictments* is incident to criminal caſes, as well as civil, when the fact, as alleged, is allowed to be true, but the priſoner joins iſſue upon ſome point of law in the indictment; by which he inſiſts that the fact, as ſtated, does not amount to the crime charged.

Some have held (2 Hal. P. C. 257.) that if, on demurrer, the point of law be adjudged againſt the priſoner, he ſhall have judgment and execution, as if convicted by verdict: but this is denied by others, (2 Hawk. P. C. c. 32. § 56.) who maintain, that in ſuch caſe he ſhall be directed and received to plead the general iſſue, not guilty, after a demurrer determined againſt him. However, upon this doubt, demurrers to indictments are ſeldom uſed; ſince the ſame advantages may be taken upon a plea of not guilty; or, afterwards, in arreſt of judgment, when the verdict has eſtabliſhed the fact. Blackſt. Comm. vol. iv. p. 334.

MURIS, JOHN DE, in *Biography*, the celebrated writer on muſic, to whom the invention of muſical characters is generally given. Fabricius, biſhop Tanner, and others, allow him to have flouriſhed about the year 1330. He is ſtyled by ſome a doctor and canon of the Sorbonne, by ſome a mathematician and philoſopher, and by others a chanter of the church of Nôtre-Dame at Paris. His country is likewiſe diſputed: for though the general opinion be that he was born at Meurs in Normandy, whence he had his name, yet, by a typographical error, he is called Parmigiano in Bontempi, inſtead of Parigino, which makes him a native of Parma, inſtead of Paris. We call it a typographical error, in order to acquit Bontempi of making J. de Muris an Italian, either from ignorance or want of integrity; as we are in poſſeſſion of a proof copy of his Storia della Muſica, in which, among other corrections made in his own hand, the word Parmigiano is changed to Parigino. But though he has no title to the invention of the time-table, as we ſhall ſoon demonſtrate, he muſt certainly have been a great benefactor to practical muſic by his numerous writings on the ſubject, which, doubtleſs, threw new lights upon the art, as may be better imagined now from the gratitude of his ſucceſſors, by whom he is ſo frequently quoted and commended, than from the writings themſelves, which Time, to whom he was ſuppoſed to have been ſo great a friend, has rendered totally uſeleſs, and almoſt unintelligible.

But though he is entitled to an honourable place among muſical worthies; yet, as both his country and profeſſion have been diſputed, all that can be done to gratify the reader's curioſity concerning him, is to give a complete liſt of his works that are ſtill preſerved in the ſeveral libraries of Europe; and, from their titles and contents, to deduce at leaſt a probable opinion of other circumſtances concerning him.

Beſides a MS. by the ſame author, in the Vatican, on the ſubject of counterpoint, we found there three others by De Muris, on the ſubject of muſic. Of the two firſt, which are in the ſame volume, No. 5221, one of which is a treatiſe on "Time, or Meaſured Muſic:" Joannis de Muris Practica Cantus Menſurabilis, pr. quilibet in Arte: This tract is likewiſe in Be'net college Camb. No. 410, in the ſame vol. as Walter Odington's treatiſe, though the author has been hitherto unknown: the other is "A Compendium of Counterpoint:" Joannes de Muris Ars Summaria Contrapuncti, pr. volentibus introduci. The third, which is among the queen of Sweden's MSS. No. 1718, conſiſts of "Muſical Theorems explained in Verſe:" Joan. de Muris Theoremata Muſica Verſibus explicata.

In the king of France's library at Paris, there are two copies of his "Speculum Muſicæ," or Mirror of Muſic, in ſeven books, which is the principal and moſt ample of all his muſical writings. This is the work mentioned by Merſennus, Du-Cange, and Rouſſeau, and in which they all tried in vain, as well as myſelf, (ſays Dr. Burney) to find proofs of his having been the inventor of the time-table.

Rouſſeau has given two conſiderable quotations from this work in his Muſical Dictionary, article DISCANT, which de Muris defines "The ſinging extempore with one or more perſons in different concords, in ſuch a manner as to produce one harmony." Diſcantat qui ſimul cum uno vel pluribus dulciter cantat, ut ex diſtinctis ſonis ſonus unus fiat, non unitate ſimplicitatis, ſed dulcis concordiſque mixtionis unione. After which he explains what he means by con-

cords, and the choice that ſhould be made of them upon theſe occaſions. He then ſeverely cenſures the fingers of his time for their ignorance and indiſcriminate uſe of them. "If our rules are good, with what front," ſays he, "do thoſe dare to *diſcant* or *compoſe*, who are ſo ignorant of concords as not to know which are more or leſs pleaſing, which ought to be avoided, or moſt frequently uſed; where to introduce them, or any thing that concerns the true practice of the art? If they accord, it is by mere chance; their voices wander about the tenor or plain-ſong without rule, truſting wholly to Providence for their coincidence. They throw ſounds about at random, as awkward people throw ſtones at a mark, without hitting it once in a hundred times."

The good maſter Muris then proceeds to flagellate with great fury theſe corruptors of the pure and ſimple harmony of his time: "Heu! proh dolor! His temporibus aliqui ſuum defectum inepto proverbio colorare moliuntur. Iſte eſt, inquiunt, novus diſcantandi modus, novis ſcilicet uti conſonantiis; offendunt ii intellectum eorum, qui tales defectus agnoſcunt, offendunt ſenſum: nam inducere cùm deberent delectationem, adducunt triſtitiam. O incongruum proverbium! O mala coloratio, irrationabilis excuſatio! O magnus abuſus, magna ruditas, magna beſtialitas, ut aſinus ſumatur pro homine, capra pro leone, ovis pro piſce, ſerpens pro ſalmone! Sic enim concordiæ confunduntur cum diſcordiis, ut nullatenùs una diſtinguatur ab aliâ. O! ſi antiqui periti Muſicæ Doctores tales audiſſent diſcantatores, quid dixiſſent? Quid feciſſent? Sic diſcantantem increparent, et dicerent: non hunc diſcantum, quo uteris, de me ſumis. Non tuum cantum unum et concordantem cum me facis. D quo te intromittis? Mihi non congruis, mihi adverſarius ſcandalum tu mihi es; O utinam taceres! non concordas, ſed deliras et diſcordas." The Latin of this paſſage is ſo obſolete and monkiſh, that it ſeems as if it would fall more naturally into Engliſh of the 16th century, than into that of the preſent times. "But, alas! in theſe our dayes, ſome do ſtryve to gloſſe over theyr lacke of ſkyll with ſilly ſayenges. This, cry they, is the *newe* method of diſcantynge, theſe be the newe concordes.—Howbeit they grievouſly offend thereby both the hearing, and the underſtanding of ſuche as be ſkylled to judge of theyr defects; for where we look for delight, they do induce ſadneſſe. O incongruous ſayenge! O wretched gloſſe! irrational excuſe! O monſtrous abuſe! moſt rude and beſtial ignorannce! to take an aſſe for a man, a goat for a lyon, a ſheepe for a fiſhe, a ſnake for a ſalmone! For in ſuche ſorte do they confound concordes with diſcordes, as ye ſhall in no wiſe diſcerne the one from the other. O! if the good old mayſters of former time did hear ſuche *diſcanters*, what would they ſay or do? Out of doubte they wolde thus chyde them and ſay, This diſcant, whereof ye now make uſe, ye do not take it from *me*; ye do in no wyſe frame your ſonge to be concordaunt with *me*; wherefore do ye thruſt yourſelves in? ye do not agree with me; ye are an adverſary, and a ſcandal unto me. O that ye wolde be dumb! This is not *concordynge*, but moſt doatynge and delyrious *diſcordynge*."

Concerning the writings upon various ſubjects by John de Muris that are ſtill preſerved among the manuſcripts of the Bodleian and Muſeum libraries, we ſhall tranſcribe the account given in Tanner's Bibliotheca Britannica, p. 537, which is ſo ample as to need little addition.

"John de Muris, or Murus, an Engliſhman, and an eminent philoſopher, mathematician, and muſician, wrote "Ex Stellarum Poſitionibus Prophetiam." Lib. i. Infra Annum certe Mundi. "Arithmeticam Speculativam." Lib. i. MS. Oxon. in Bibl. Publ. Impreſſ. Mogunt. "Tractatum Muſicum." Lib. i. Quoniam Muſica eſt de Sono relato ad Numeros. MS. Bodl. N. E. F. 10, 11. "Artem componendi (metiendi) fiſtulas Organorum ſecundum Guidonem." Lib. i. "Cognita conſonantia in Chordis. Ibid." "Sufficientiam Muſicæ Organicæ editam (ita habet MS.) a Mag. Joanne de Muris, Muſico Sapientiſſimo, et totius orbis Subtiliſſimo experto." Pr. Princeps Philoſophorum Ariſtoteles. Ib. "Compoſitionem Conſonantiarum in Symbolis ſecundum Boëtium." Pr. Omne Inſtrumentum Muſicæ. Ib. "Canones ſuper Tabulas Alphonſinas." Pr. Quia ſecundum Philoſophum, 4to. Phyſicorum. MS. Bodl. Digby 168. f. 132. "Collectionem Prophetiarum de Rebus Anglicis, per Joh. de Muris." MS. Cotton. Veſpaſ. E. VII. 8. In MS. Bodl. Digby 190. fol. 72. extat "Prologus in Opus, cui Titulus; Tractatus Canonum minutiarum Philoſophicarum et Vulgarium, quem compoſuit Mag. Johannes de Muris, Normannus A. MCCCXXI. a quo eodem anno (verba ſunt autoris) Notitia Artis Muſicæ proferendæ et figurandæ tam menſurabilis quam planæ, quantum ad omnem modum poſſibilem diſcantandi, non ſolum per integra, ſed uſque ad minutiſſimas fractiones:" "Cognitioque circuli quadraturæ" perfectiſſime demonſtratæ: "Expoſitioque tabularum Alphonſi" regis Caſtelliæ: et "Genealogiæ Aſtronomiæ" nobis claruit, &c. "Canones de Eclipſibus." Pr. In oppoſitione habenda aliud. MS. Bodl. Digby 97. ubi habetur hæc nota: Hos Canones diſpoſuit Joannes de Muris Pariſiis in A. MCCCXXXIX. in Domo Scolarium de Sorbona. "De Conjunctione Saturni et Jovis," A. MCCCXLV. Pr. Tres Principes ex Militia. MS. Bodl. Digby 176. Bal. XI. 74. Pits. App. p. 872. ſeq."

As all the tracts in the liſt of his writings which concern muſic have been carefully examined, we will endeavour to convey to the reader an idea of their contents.

The tract which begins "Quoniam Muſica eſt de Sono relato ad Numeros," is now marked Bodl. 300. It is a treatiſe of Harmonics, in which the circular and conical diagrams and diviſions of the ſcale are innumerable. The author is as fond of the circle in this work, as Tartini was four hundred years after. The tranſcriber has, however, omitted many of theſe illuſtrations of his doctrines, by which, perhaps, the injury to muſical ſtudents of the preſent age is not very conſiderable. "Explicit Muſica Magiſtri Joannes de Muris."

What follows in the manuſcript is manifeſtly a continuation of the ſubject, and a ſecond part of the preceding tract. It begins thus: "Princeps Philoſophorum Ariſtoteles ait in Principio Mathematicæ ſuæ omnino Scientis Signum eſt poſſe docere." We find after the introduction a repetition of the initial ſentence of the firſt part: "Quoniam Muſica eſt de Sono relato ad Numeros." This part, however, relates more to the practice of muſic than the other.

In his chapter "De Tempore perfecto et imperfecto," he ſeems to call common time perfect, and triple time imperfect: for, he ſays, "quod longa poſſit imperfici per brevem. Brevis per ſemibrevem. Semibrevis per minimam. Quod minima non poſſit imperfici." However, by theſe words, he, perhaps, only means to ſay that a long, which by itſelf is perfect, or equal to three breves, by poſition may be rendered imperfect, that is, equal to two breves only, by a breve, the next ſhorteſt note being placed after it; and ſo a breve, which alone, or with other breves, is triple, becomes double by a ſemibreve following it. What he means by ſaying that a minim cannot be imperfected in the ſame manner, is, that there was no ſhorter note, the crotchet not being then invented, to perform the operation. In his Diagrams of Muſical Proportions, or Time Tables, he gives but four

kinds of notes; that is, in four columns; for in theſe are manifeſtly five diſtinct forms of characters: as  .

The ſcale of Guido, in a perpendicular diagram; and the hexachords, which are well arranged under their ſeveral denominations of durum, naturale, and molle, are exhibited in this tract.

In the tract by John de Muris, beginning "Quilibet in arte," which we unexpectedly found in Be'net college, Cambridge, in the ſame volume as Odington's treatiſe, the notes are divided into five claſſes: "Quinque ſunt partes prolationis, videlicet, maxima, longa, brevis, ſembrevis et minima," ut hic —giving the ſame characters as in the tract juſt mentioned: and here, likewiſe, his doctrine agrees with that in his other treatiſe, where he ſeems to call the triple proportions imperfect, and the dual perfect.

This is the moſt ancient manuſcript in which we have found the ſigns of the modes, C ☉ ○ ⊙, and the "punctum perfectionis." Here it plainly appears that the punctum, or point, in John de Muris, operates in the ſame manner as that already deſcribed in Franco, p. 187, where it makes the note to which it is prefixed *perfect*, that is, of three times; and the calling it "punctum perfectionis," or point of perfection, prove its power of making a double quantity triple, as at preſent. At the bottom of fol. 6. is written, "Explicit tractatus Joannis de Muris:" however, it goes on for fifteen pages more. Here, too, we firſt ſaw an open, or white minim,  and a half lozenge note  . The ink is pale, and the writing very bad, and difficult to decipher; but the manuſcript, which is written on paper of a coarſe texture, ſeems entire, and correſponds in every particular with that in the Vatican library, No. 5321. It was this treatiſe which Proſdocimo de Beldemandis of Padua, a voluminous writer on muſic in the beginning of the fifteenth century, thought of ſufficient importance to merit a commentary, which is now in the poſſeſſion of Padre Martini of Bologna. "Practica Menſurabilis Cantus," Mag. Joan. de Muris, de Normandia, alias Pariſienſis, cum expoſit. Proſdocimo de Beldemandis Patav. MS. an. 1404.

The tract by J. de Muris, in the Bodleian library, upon the meaſures, and proportions of organ-pipes, according to Guido, beginning "Omne inſtrumentum muſice," is very ſhort, and contains nothing very important to muſic at preſent. It is not known that Guido ever wrote on the ſame ſubject, and de Muris only means by "ſecundum Guidonem," to ſay that he has followed the ſame proportions which Guido eſtabliſhed in his diviſion of the monochord.

In another ſhort tract of the ſame volume he follows Boëthius. And in his "Tractatus Canonum minutiarum Philoſophicarum et vulgarium," where he tells us that he had compoſed at the ſame time "a Treatiſe on the Art of Muſic," teaching and deſcribing in figures or notes both meaſured and plain-ſong, with every poſſible kind of diſcant, not only by integers or long-notes, but by the ſhorteſt and moſt minute fractions, he probably alludes to his "Speculum Muſicæ," in ſeven books, which ſeems the moſt voluminous of all his writings, but the invention of the Characters for Time, which has been given to de Muris, by almoſt all the writers on muſic of the two laſt centuries, and whom many Engliſh authors ſeem ambitious of claiming as their countryman, probably with the hopes of honouring this kingdom with his invention of the time-table. But however patriotic may be their deſign, we are in poſſeſſion of ſuch a ſtubborn proof, from his own acknowledgment, of that diſcovery not being his property, as he would be unable to refute, if he could riſe from the tomb and claim it.

Among the MSS. which were bequeathed to the Vatican library by the queen of Sweden, there is a "Compendium of Practical Muſic," by John de Muris, in which he treats of muſical characters for time; but introduces the ſubject with a ſhort chronological liſt of anterior muſicians who had merited the title of *Inventors:* beginning, as uſual, with Tubal; and, after naming Pythagoras and Boethius, he proceeds to Guido, the monk, "who conſtructed the gammut, or ſcale for the monochord, and placed notes upon lines and ſpaces; after whom came Magiſter Franco, who invented the figures, or notes, of the Cantus Menſurabilis."—Deinde Guido monachus qui compoſitor erat gammatis qui monochordum dicitur, voces lineis, et ſpaciis dividebat. Poſt hunc Magiſter Franco, qui invenit in cantu menſuram figurarum. MS. Reginæ Sueciæ in Vatic. No. 1146. "Compendium Joannes de Muribus."

With reſpect to the diſpute concerning the place of his nativity, though Tanner, copying Pits and Bale, calls him an Engliſhman, yet we find that in the title of one of the manuſcripts of the Bodleian library, in Tanner's liſt, he is called a Norman, and in another a Pariſian. Padre Martini likewiſe quotes a manuſcript of the year 1404, in which he is called the Great John de Muris, de Normandia, alias Pariſienſis.

Having taken ſome pains to trace the opinion of his being an Engliſhman to its ſource, we have been able to find no ſuch title given to him in any of his numerous writings that have been preſerved in manuſcript throughout Europe. The aſſertion reſts entirely on Robert Record, a phyſician at Cambridge, and one of the firſt writers upon ſcience in the Engliſh language. His works were very voluminous, of which, however, little more remain than the titles preſerved in Pits' account of him, which ſays, that he was living in 1552. (Append. Illuſt. Ang. Script. tom. i. p. 872.); at leaſt, we have never been able to procure any of his writings, except his Arithmetic, printed in black letter 1543. And as John de Muris had written on the ſame ſubject (Arithmeticam Speculativam, l.b. duos,) we had hopes of meeting in this tract the place where Record calls him an Engliſhman; but no ſuch could be found.

Pits, (loc. cit.) calls him an Engliſh mathematician, and ſays, "he was a man of ſome genius, but poſſeſſed of too daring a curioſity; for, while he was ſtudying philoſophy, he addicted himſelf to mathematics, and to that more ſublime part of aſtronomy which contemplates the heavens: and in the exerciſe of his genius for calculation, he had the inſolence to predict future events; thus perſuading the ignorant and vulgar, that by the aſpect of the ſtars he could penetrate the decrees of Providence. He dared to publiſh celeſtial ſecrets under the title of Prophetiarum, prophecies."

Theſe particulars, and many more, he ſays, were collected from Robert Record. But neither from him nor any one elſe was he able to diſcover at what time he lived. Bale, who calls him a mathematician and a conjurer (*Mathematicus et Vates*) gives the ſame authority for his being an Engliſhman.

This bare aſſertion, made at a time when it was not ſo cuſtomary to give or expect proofs and critical exactneſs in ſupport of facts as at preſent, has not only been copied, without farther enquiry by Pits, Bale, and Tanner, at home, but by Fabricius and other reſpectable writers on the continent. A Latin diſtich, by an anonymous writer, which has been quoted in favour of this opinion, can add but little to its weight, when it is known to come from the moſt ignorant

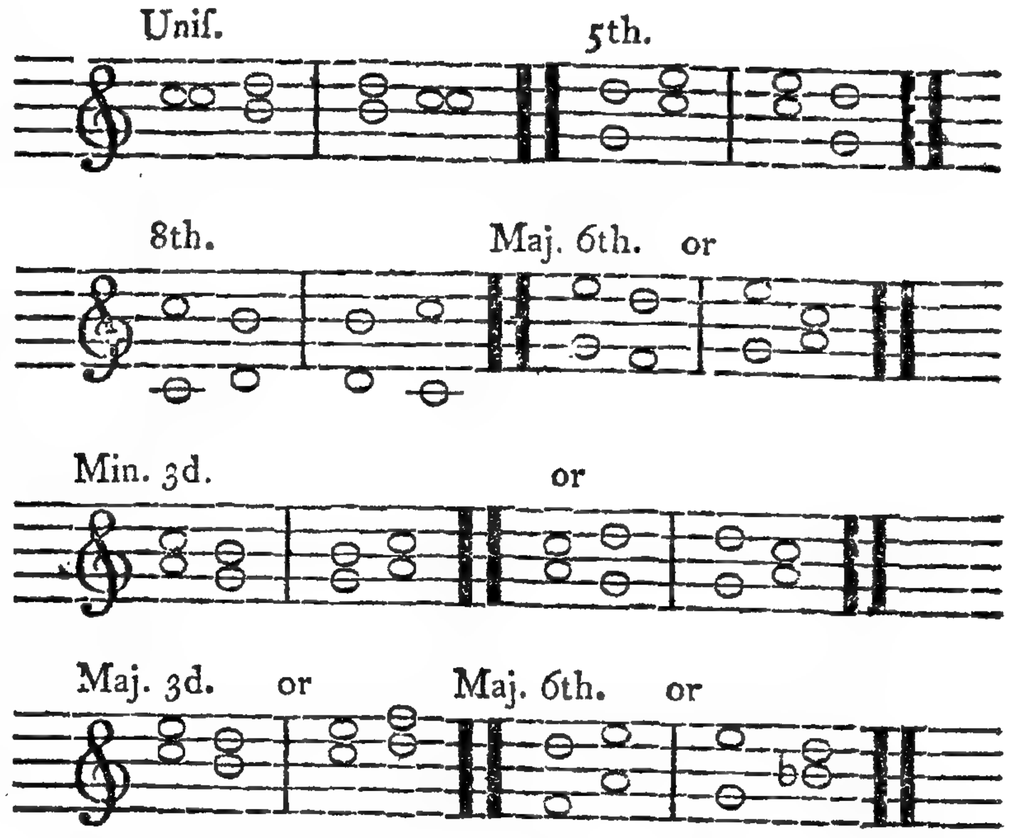
and monk'ſh of writers, the author of a treatiſe "De Origine et Effectu Muſice," written 1451; who tells us that "Cyrus lived ſoon after the deluge; that one king Enchiridias was a writer on muſic," miſtaking, I ſuppoſe, ſome Enchiridion which he had ſeen, for the name of a royal author: And that "Thubal kept a blackſmith's ſhop, at which Pythagoras adjuſted the conſonances by the ſound of his hammers." But ſuch authority will be found no more to prove J. de Muris an Engliſhman, than Guido or Franco, as both thoſe writers equally contributed to the progreſs of muſic in this kingdom; and it may as well be inſiſted upon, that, becauſe Metaſtaſio has enriched this country with many beautiful ſongs, he muſt conſequently be a native of England.

That monks and perſons of learning, for many centuries before the Reformation, were more frequently diſtinguiſhed by the name of the place which gave them birth joined to their baptiſmal appellation, than by their family name, is moſt certain: as Guido Aretinus, Geoffry of Monmouth, Henry of Huntingdon, William of Malmſbury, John of Saliſbury, Mathew of Weſtminſter, &c. who have been always ſuppoſed natives, or, at leaſt, inhabitants, of the ſeveral places by which they were called. Now, though no town in Normandy of the name of Meurs can be found, either in maps or geographical books, yet, as there are ſeveral places ſo called in France, particularly one in Touraine, and another in Anjou, near Angers, which by giving birth to our John, ſerved to diſtinguiſh him from his innumerable nameſakes of other kingdoms, cities, and profeſſions; and as no ſatisfactory or probable reaſon has been aſſigned for ſuppoſing him an Engliſhman, nor can any one be now ſuggeſted, except a patriotic deſire of appropriating to our own country a man whoſe learning and talents have been long celebrated, it is but juſt to reſtore him to that country which ſeems to have the faireſt claim to him.

John de Muris, though not the inventor of the "Cantus Menſurabilis," ſeems, by his numerous writings, greatly to have improved it. Indeed, every ſpecies of note to be found in his tracts, except the minim, is deſcribed in Franco, as well as uſed in compoſitions anterior to his time, and mentioned by authors who wrote upon muſic before him. Nor is it poſſible to imagine that this art was invented and received by all Europe at once: like others, it had its beginning, improvements, and perfection, in different periods of time. His "Art of Counterpoint," of which we procured a copy at Rome, though compriſed in a few pages, is, however, the moſt clear and uſeful tract on the ſubject, which thoſe times could boaſt.

He begins, by informing his reader, that, beyond the octave, all is repetition. That, "within the octave there are ſix ſpecies of concord, three perfect, and three imperfect: of the firſt kind are the uniſon, 8th and 5th: and of the ſecond, the two 3ds, and major 6th. The firſt of the perfect kind, he ſays, is the uniſon, which, though by ſome not allowed to be a concord, yet, according to Boethius, it is the ſame, and the origin of all conſonance. The uniſon naturally requires after it a minor 3d; which, on the contrary, for variety, is beſt ſucceeded by a perfect concord. The 5th being of the perfect kind, is well followed by a major 3d, and *è contra*. The octave, another perfect concord, may be ſucceeded by the major 6th; after which, either a perfect or imperfect concord may be taken. It is the ſame with the minor 3d, which, being of the imperfect kind, may be ſucceeded either by a perfect or imperfect concord. The major 3d, though beſt followed by a 5th, yet may be ſucceeded by another 3d, but then it muſt be minor. The major 6th, too, though beſt followed by an 8th, may yet be ſucceeded either by a perfect or imperfect concord of another ſpecies, for the ſake of variety; it can be followed by a fifth only when the under part riſes a major or minor 3d; but by 3ds and 6ths at pleaſure. Every compoſition ſhould begin and end in a perfect concord; and it muſt be remembered that no two parts ſhould aſcend or deſcend in perfect concords, though imperfect may be uſed without limitation: and, laſtly, care muſt be taken, that when the under part aſcends, the upper ſhould deſcend, and the contrary."

Moſt of theſe rules were given by Franco, but with leſs clearneſs and preciſion; and as they will not only ſhew that harmony had made ſome progreſs in the fourteenth century, but are ſuch as would not ſhock modern ears, we ſhall preſent them to the muſical reader in notes.



The minor 6th, we know not why, is called a *diſcord* by Franco, and has no admiſſion among concords, by John de Muris; though it is only an inverſion of the major 3d, which both allow to be a concord.

John de Muris makes no mention of the 4th in this tract, though, in his "Speculum Muſicæ," he gives rules for diſcanting in a ſucceſſion of fourths, under the barbarous term *diateſſaronare*.

DEMY SANGUE. See HALF-BLOOD.

DEN, a ſyllable added to the names of places, and ſhews their ſituation to be in a valley, or near woods, as Tenterden, Biddenden, &c.

The word is Saxon *den, i. e. vallis*, or *locus ſylveſtris*.

DEN *and ſtrond*, &c. in *Law*, was a liberty for ſhips or veſſels to run or come a-ſhore. King Edward I. by charter, granted this privilege to the barons of the cinque ports.

DENA, in *Geography*, a river of Hindooſtan, S.E. of Adjodin, being one of the four branches of the Setlege (probably the Dond), and, perhaps, ſays Mr. Rennell, the only principal one among them, exeept the Beyah.

DENAIN, a ſmall town of France, in the department of the North, near the river Scheldt, between Valenciennes and Bouchain, remarkable for its abbey, founded by a daughter of king Pepin, and for a victory gained in its neighbourhood by the French, under the duke of Villars in the year 1712, over the allies, after the departure of the Engliſh.

DENARIATUS TERRÆ, in *Ancient Law-Books*, as much land as is worth a penny by the year. See FARDING-*deal*.

"Sibylla Barthelot tenet unam acram, & 5 *denariatos* terræ in eodem tenemento." Du-Cange.

DENARII, in *Antiquity*, a general term for any ſort of *pecunia numerata*, or ready money. Paroch. Antiq. 320.

DENARII *de Caritate*, cuſtomary oblations made to cathedral churches about the time of Pentecoſt, when the pariſh prieſts, and many of their people, went in proceſſion to viſit their mother church. This cuſtom was afterwards changed into a ſettled due, and uſually charged upon the pariſh prieſt; though at firſt it was but a gift of charity, or preſent, for helping to maintain and adorn the biſhop's ſee. Cartular. Abb. Glaſton.

DENARIUS, the Roman penny; a ſilver coin, equivalent to, from ſix to eight-pence half-penny ſterling. See COIN.

The Romans having, for a long time, uſed braſs money, which they call *as*, quaſi *æs*; or *libra* and *pondo*, becauſe it was a pound weight; began in the year of Rome 485, or 269 years B.C. to coin ſilver; and coined firſt the denarius, which was marked with the letter X, becauſe it is worth ten aſſes, whence its name, and divided into two quinarii, marked with V, which were ſubdivided into two ſeſtertia, marked with theſe three letters IIS. The as was then of 3 ounces, and allowing, which was probably the caſe, that theſe large denarii of 90 grains at a medium, are of the firſt coinage, the proportion of copper to ſilver was as 1 to 160. Afterwards, when the denarius was of 60 grains at a medium, and the as of 2 ounces, copper was ſtill to ſilver as 1 to 160; but when the as fell to only an ounce, copper was to ſilver as 1 to 80; and when it fell to half an ounce, and 16 went to the denarius, it was as 1 to 64, at which rate it remained. With us copper to ſilver is in coinage 1 to 40; but in actual value 1 to 72. The denarius was worth eight-pence of our money, the quinarius four pence, and the ſeſtertius, whether ſilver or braſs, two-pence. Afterwards, about the year 579, or 175 years B.C., when the as fell to half an ounce, the ſilver denarius was made to paſs for ſixteen aſſes, the quinarius for eight, and the ſeſterce for four; but in the pay of the army, the ſoldier generally received a ſilver denarius for ten aſſes, (Pliny, Nat. Hiſt. lib. xxxiii. cap. 3. Livy, lib. xv) though not without ſome variations and deductions. The denarius continued at this value till the time of Gallienus. Under Caracalla, or probably under his predeceſſor, Severus, who firſt debaſed the ſilver coinage, there were denarii ſtruck of two ſizes. The large denarius of Caracalla, and his ſucceſſors, is one-third heavier than the uſual one, and it may be reaſonably concluded that it bore one-third more value; and was worth 6 braſs ſeſtertii, while the other retained its firſt value of 4. This large denarius of courſe had 24 aſſaria; and it is called by the writers of the Auguſtan hiſtory, and in reſcripts of the period, *Argenteus*, or the ſilver piece, and *Argenteus Philippus*, or the ſilver Philip, the word *Philip* having become a familiar appellation for any coin. The common denarii now firſt began to be termed *minuti*, and *argentei Philippi minutuli*, and the like, to expreſs their being ſmaller than the others. The firſt *argenteus* is worth nearly one ſhilling ſterling.

From the time that Caracalla ſtruck the large denarius, both it and the ſmall had been leſſening by degrees; till after Gordian III. the latter totally vaniſhed, and the large alone remained. This, in the time of Gallienus, was the ſole denarius of ſilver, and ſo much diminiſhed, as only to equal the *minutus*, or ſmall one, of Caracalla. But Gallienus introducing the *denarii ærei*, which was copper waſhed with ſilver, and of the ſize of the denarius, inſtead of the ſeſtertii, the *argenteus*, though reduced more than a third in ſize, bore 6 *denarii ærei*, its old ſtandard of *ſeſtertii*. Writers of the period, and after, ſay, that the *denarius*, or *argenteus*, was of 60 aſſaria; hence it follows that each *denarius æreus* had 10; and received its name from that circumſtance, as well as its being of the ſize of the ſilver denarius. Theſe aſſaria are of the ſize of the argentei; and ſhew that copper retained its old proportion to ſilver of about 1 to 60. The denarii or argentei continued to be coined in the time of Conſtantine I., and were the money moſt common in currency. As they had been rated at 100 to the pound of ſilver in tale, they began to be called *centenionales*, or *hundreders*. They then diminiſhed very faſt in ſize; thoſe of Conſtantine I. and II., Conſtans, and Conſtantius weigh 50 grains down to 40; thoſe of Julian II., Jovian, 40 down to 30; thoſe of later princes, till Juſtinian, 30 to 20. Under Heraclius, when they ceaſed, the denarii were from 15 grains down to 10. The miliarenſis, which was ſubſtituted by Conſtantine in the room of the denarius, attends the denarius in proportional decline of ſize. See MILIARENSIS and POUND.

The moſt ancient denarii have on one ſide the head of a woman in a helmet, with the inſcription ROMA, and the mark of the denarius X or , and ſome few XVI, and a biga or quadriga on the other; whence they are denominated bigati and quadrigati. The next to theſe in antiquity, have the head of Roma, or ſome other deity, on one ſide, and on the reverſe the name of the mint-maſter, with hiſtorical or emblematical figures. Many of theſe have the mark X or  , which remained long after the denarius paſſed for 16 aſſes. A third ſort have the head of a conſul or general on one ſide, with an hiſtorical or emblematical reverſe: few of theſe have the mark X or  , upon them. Theſe three ſorts are called conſular denarii, becauſe they were ſtruck during the republican government by conſuls. The imperial denarii have commonly the head of the reigning emperor, with his names and titles on one ſide, and ſome emblematical figures on the reverſe, with ſuitable inſcription. The Romans did not uſe the denarius for a weight, as the Greeks did their drachm, till the Greek phyſicians coming to Rome, and finding the two coins nearly equal, preſcribed by it, as they had been uſed to do by the drachm in their own country.

We are informed both by Celſus and Pliny, that eighty-four denarii were coined out of the pound of ſilver; and therefore by determining the true weight of the Roman pound, we ſhall obtain that of the denarius, which depended upon it. But the Roman pound in tale exceeded it, in like manner as our pound in tale falls ſhort of our pound in weight; the Roman pound in tale conſiſted of 100 denarii. Celſus de Medicina, lib. v. cap. 17. Pliny, Nat. Hiſt. lib. xxxiii. cap. 9.

If we take 5040 troy grains for the weight of the Roman pound, as determined from the gold coins, the conſular denarius of 84 in the pound will weigh juſt 60 troy grains. Mr. Raper took the mean weight of forty-ſix of the faireſt denarii in the Britiſh Muſeum, and found it to be 60.95 troy grains; but as ſome of theſe were imperfect, he found the mean of twenty perfect denarii to amount to 60.92: and he queſtions whether the denarii of above ſixty-three grains ever paſſed as current coin. The weight of the denarius was diminiſhed under the emperors; and Greaves found, by examining many imperial denarii, that from Auguſtus's time to Veſpaſian they continually almoſt decreaſed, till, from being the ſeventh part of the Roman ounce, they came now to be the eighth part; and ninety-ſix were coined out of the Roman libra, whereas under the conſuls they coined only

eighty-four. Under Severus and Gordianus they recovered their weight, but with a conſiderable mixture of allay. J. Caſpar Eiſenſchmid of Straſburg, in a book "De Ponderibus et Menſuris Veterum." &c. publiſhed in 1708, informs us, that he found the weight of the imperial denarius from Nero to Sept. Severus, to be to the conſular denarius in the proportion of 7 to 8.

In order to determine the value of the conſular denarius of 60 troy grains of fine ſilver, we are to conſider, that ſixty-two Engliſh ſhillings are coined out of eleven ounces two penny weight, troy, of fine ſilver, and eighteen penny weight allay; and therefore the troy grain of fine ſilver is worth $\frac{62}{1111}$ths of a farthing; and ſixty grains, or the denarius, worth ſomewhat more than eight-pence farthing and a half ſterling; and the as, or ſixteenth part of the denarius, a little more than a half-penny. Phil. Tranſ. vol. lxi. part. ii. art. 48.

Others, as Greaves, and after him Arbuthnot, have made the conſular denarius the ſeventh part of an ounce in weight, a little more than ſixty-two grains, allowing 5256 troy grains to the Roman pound, and its value, allowing eight Engliſh grains to the ſilver penny, $7\frac{3}{4}d.$ of our money; and the imperial denarius the eighth part of an ounce, and worth about $6\frac{1}{2}d.$ ſterling.

M. Tillemont obſerves, that the denarius was held ſufficient to keep a perſon handſomely for a day; and, upon the whole, ſeems to intimate, that it was equal to twelve French ſous, or eleven Engliſh pence; but this eſtimate errs in exceſs more than the preceding does in defect. See Greaves's Diſcourſe of the Denarius, in his works, by Dr. Birch, vol. i. p. 235, and Arbuthnot on Coins, p. 15.

Denarius is alſo uſed, in our *Law books*, for an Engliſh penny.

"Denarius Angliæ, qui nominatur ſterlingus, rotundus ſine tonſura, ponderabit 32 grana frumenti in medio ſpicæ; & 20 denarii facient unciam; & 12 unciæ facient libram." Stat. Ed. I. De menſuris.

Denarius *Dei* denotes earneſt-money; called alſo argentum Dei, by the French deniers de Dieu, and in ſome parts of our country arles.

"Ita quod neuter mercatorum ab illo contractu poſſit diſcedere, vel reſilire poſtquam denarius Dei inter perſonas contrahentes datus fuerit & receptus." Charti Eduardi I.

Denarius *tertius comitatus*, denoted a third part of the profits of county courts. When thoſe courts had ſuperior juriſdiction, before other courts were erected, two parts of the fines, and other profits belonging to them, were reſerved to the king, and a third part to the earl of the county. Paroch. Ant. 418.

Denarius *Sti. Petri*. See Peter-pence.

DENAROS, in *Ancient Geography*, an iſland ſituated at the eaſtern extremity of the iſle of Cyprus, near the promontory Dineratum.

DENAT, in *Geography*, a ſmall town of France, in the deparment of the Tarn, on the river Agout; 9 miles S. of Alby.

DENATES, in *Antiquity*, domeſtic gods, more frequently called *Penates*, which ſee.

DENAVACA, in *Geography*, a town of the iſland of Ceylon; 50 miles S. of Candy.

DENBERA, in *Antiquity*, from the Saxon *Den*, a vale, and *berg*, a hog, denoted a place for the rearing and feeding of hogs, in which they are penned; called by ſome a *ſwine-comb*.

DENBIGH, in *Geography*, the county town of Denbighſhire, North Wales, is ſituated on the ſide and at the top of a craggy and lofty hill, which riſes out of the beautiful and fertile vale of Clwyd. This place was called by the Britons *Cledfryn yn Rhos*, or the craggy hill in Rhos. This part of the county was given by Edward I. to David ap Gruffydd, brother to Llewelyn the laſt prince of North Wales, who being afterwards beheaded for high treaſon, it was given to Lacy, earl of Lincoln, who fortified the town with a ſtrong wall, and either built, or enlarged the caſtle; but his only ſon being unfortunately drowned in the well of this caſtle, his grief was ſo great that he was induced to leave it unfiniſhed. After the earl's death, it went by the marriage of his daughter Alice, into the poſſeſſion of the family of the houſe of Lancaſter. Edward II. gave it to Hugh Spencer; after which, in the reign of Edward III., Roger Mortimer became the poſſeſſor, and fixed his arms on the chief gate; but he being executed for high treaſon, it went to Montague, earl of Saliſbury, and was ſoon afterwards reſtored to the Mortimers. After many changes it came to the houſe of York, and now belongs to the crown. Charles I. reſided in it ſome time. It was delivered up to the parliamentary army in 1646, and appears to have been a place of ſuch ſtrength, that after the reſtoration it was thought adviſable to blow it up. The ruins of the caſtle are ſtill to be ſeen on the ſummit of a rock, which ſlopes on all ſides but one, which is a precipice. The principal part of the caſtle was built anno 1280, temp. Edward I. The grand entrance was through a large gate, with a pointed arch, flanked by two octagonal towers. The caſtle ſeems to have been of a ſingular conſtruction: two walls being built ſeveral feet aſunder, the intervening ſpace was filled up by pouring in a mixture of mortar and rough ſtones, which formed, in drying, a maſs as ſolid as the rock itſelf. The proſpect from the caſtle is particularly grand and delightful, commanding an extenſive reach of the banks of the Clwyd, interſperſed with gentlemen's ſeats. Denbigh is a borough town, governed by two aldermen, a recorder, two bailiffs acting as ſheriffs, and twenty-five capital burgeſſes, who form a common council. The aldermen are juſtices, and hold quarter-ſeſſions in the ſame manner as the county ſeſſions are held, by ſtatute. The borough returns one member to parliament: the election is veſted in the reſident burgeſſes, in number about five hundred; the bailiffs are the returning officers. The political influence is entirely in the Middleton family, of Chirk-caſtle, whoſe anceſtors have repreſented the borough in various parliaments from 33 Henry VIII. to the preſent time. The town is not large, but generally well built, and contains 534 houſes and 2391 inhabitants, of whom 794 were returned as being employed in trade and manufacture, particularly of ſhoes, gloves, and other articles of leather, in which commodities the town carries on a conſiderable traffic. Denbigh gives the title of earl to the noble family of Fielding. Near the caſtle ſtands the chapel of St. Hilary, which is the common place of worſhip for the inhabitants of the town; as the pariſh church and burial ground are about a mile diſtant in the bottom of the vale. Near the lower end of the town, in the pariſh of Henllan, ſtood a priory of White Friars; but little of it remains except a part of the church, now converted into a barn. Here are alſo the ruins of an abbey of Black Monks of the Benedictine order, founded and endowed by Adam Saluſbury, in the reign of Henry III. Denbigh is diſtant from London 218 miles N. W. Evans' Cambrian Itinerary.

Denbigh, *Cape*, a point of a peninſula, on the American coaſt, ſouth of Norton Sound, obſerved in captain Cook's third voyage in 1778, firſt ſuppoſed to be an iſland, but afterwards found to be united to the continent by a low neck of land, on each ſide of which the coaſt forms a bay. N. lat. 64° 30′. E. long. 198° 30′. The captain had ſome intercourſe

intercourſe with the natives, who exchanged a few dry fiſh for ſuch trifles as they could procure; but they were moſt deſirous of knives, and had no diſlike of tobacco. Lieutenant Gore, who was ſent to examine the peninſula, found there was little freſh water, and that the wood was difficult to be obtained, as the boats grounded at ſome diſtance from the coaſt. To the ſouthward of cape Denbigh, was an iſland named "Beſborough iſland," S. 52° E., 15 leagues diſtant. The adjacent country, where there was no wood, was covered with heath and other plants, ſome of which produced abundance of berries. The underwood, ſuch as birch, willows, and alders, rendered it troubleſome walking amongſt the trees, which were all ſpruce, and none of them above 6 or 8 inches in diameter. All the drift-wood in theſe northern parts was fir. The natives in their ſize and features reſembled thoſe whom the voyagers had met with on every other part of the coaſt, King George's Sound excepted. As they approached the ſhip, they ſang, while one of their number beat upon a kind of drum, and another made a thouſand antic motions with his hands and body; but there was nothing ſavage either in the ſong, or in the geſtures that accompanied it. Their clothing conſiſted principally of deer-ſkins; and they obſerved the cuſtom of boring their under lips, and fixing ornaments to them. Their habitations, ſeated cloſe to the beach, conſiſted ſimply of a ſloping roof, without any ſide walls, compoſed of logs, and covered with graſs and earth. The entrance was at one end; the fire-place juſt within it; and a ſmall hole near the door let out the ſmoke. Although they had ſome beads, the article which they ſeemed chiefly to value was iron; and for four knives made out of an old iron hoop, they gave 400 pounds weight of fiſh, ſome being trout, and the reſt in ſize and taſte between a mullet and herring. The berries procured here were wild currant-berries, hurtle-berries, partridge-berries, and heath-berries. The low land connecting this peninſula with the continent was full of creeks, and abounded with ponds of water, ſome of which in the month of September were frozen over. Here were a great many geeſe and buſtards, ſome ſnipes, and on the high ground partridges of two ſorts. In the wood, muſquitoes were in great plenty. This peninſula ſeemed to have been in remote times an iſland; for there were marks of the ſea having flowed over the iſthmus, and it appeared to be kept out by a bank of ſand, ſtones, and wood, thrown up by the waves. Cook's Third Voyage, vol. ii. p. 485. See Norton's *Sound*.

DENBIGHSHIRE, a county of North Wales, is bounded on the weſt by Caernarvonſhire; on the north by the Iriſh ſea; on the eaſt by Flintſhire, Cheſhire, and Shropſhire; and on the ſouth by Merionethſhire and Montgomeryſhire. This diſtrict is divided into ſix hundreds; and extends from north-north-weſt to ſouth-eaſt about thirty-nine miles; while its greateſt breadth from eaſt to weſt does not exceed twenty-three miles. This extent is not accurately aſcertained, as there has never been a correct ſurvey of the county. Mr. Kay, who drew up a conciſe agricultural report reſpecting Denbighſhire, ſtates, that it contains about 410,000 acres of land, the greater part of which is rugged and mountainous, but the lower grounds being incloſed, and in general well wooded, with a great variety of very rich valleys interſperſed, conſiderably ſoften its appearance. The ſoil is various, conſiſting of gravel, clay, and loam; chiefly loamy gravel and ebb ſhale. The air is ſalubrious; and the inhabitants in general long-lived. The principal rivers are the Clwyd and the Conway; the former paſſes through the vale of the ſame name; whilſt the latter is the boundary between this county and Caernarvonſhire. All the country about Wrexham (the moſt populous, and largeſt town in North Wales, lying on the eaſtern parts of this county,) is beautifully variegated. Chirk caſtle, the ſeat of Mr. Middleton, within twelve miles from Wrexham, is pleaſantly ſituated on a riſing ground, commanding a moſt extenſive view, although ſurrounded with large and very valuable plantations. Wynſtay, the ſeat of ſir Watkin Williams Wynne, which lies half-way between Chirk and Wrexham, is alſo a moſt delightful ſituation, with extenſive old plantations; beſides a great number of other gentlemen's ſeats, all of which are encompaſſed with fine woods. The banks of the Dee afford excellent paſture and hay. The moſt extenſive valley in this county is the celebrated vale of Clwyd, in which are a number of towns, villages, and gentlemen's ſeats. It is above twenty miles in length, and from three to eight miles in breadth, according to the approach or receſs of the mountains, with which it is guarded on all ſides except on the north. This vale is in general in a high ſtate of cultivation; though the weſtern parts are more barren, except on the ſea coaſt. The crops principally cultivated are wheat, oats, barley, and peas, with red and white clover, and rye-graſs, potatoes, and a few turnips. Denbighſhire contains 57 pariſhes, and 12,621 houſes, inhabited by 60,352 perſons, of whom 6,960 were returned as being employed in trade and manufacture, and 21,104 in agriculture. Wool is the principal object of manufacture of the county, and is wrought into cloths of different qualities, and alſo into ſtockings, particularly thoſe called Angola hoſe. Near the village of Chirk are a foundery for cannon, and alſo ſome iron forges. The borders of the county afford ſome lead mines; and in the ſouth-weſtern parts coal-pits are worked. The chief products of this county are cattle, corn, and cheeſe: the latter in ſome parts, particularly in the fine paſture land on the banks of the Dee, is equal in quality to that made in Cheſhire. Denbighſhire returns two members to parliament; one for the county, and one for the county-town. It lies partly in the dioceſe of St. Aſaph, and partly in that of Bangor. "Kay's General View of the Agriculture of North Wales." "Evans's Cambrian Itenerary."

DENCHE', Denchea, or *Endenché*, in *Heraldry*. See Danche'.

DENDER, in *Geography*, a river of Flanders, which runs into the Scheldt at Dendermond.

DENDERA, the ancient *Tentyris* or *Tentyra*, a town or large village of Egypt, built near the ruins of the ancient city at a ſhort diſtance from the weſt bank of the Nile, at the extremity of a very fertile plain, about 242 miles S. of Cairo, and 48 S.S.E. of Girgé. The ſurrounding orchards, which produce excellent oranges, lemons, pomegranates, grapes, and figs, render it a charming place, and afford a delightful coolneſs in a ſcorching country. A foreſt of palms and fruit-trees, mentioned by the ancients, ſtill exiſts in its environs, and furniſhes the greateſt part of the charcoal that is conſumed in Egypt. An Arabic prince, with the title of emir, has a ſovereign authority over Dendera and the circumjacent country; but he pays a tribute to the beys of Cairo. The ſite of Tentyris, which was formerly a celebrated city of Egypt, and gave its name to the nome Tentyritus, of which it was the capital, is little more than a quarter of a league from the preſent village of Dendera, towards the mountains to the weſtward. This city was of great extent, and, from its ſplendour, was reckoned one of the moſt conſiderable cities. Iſis and Venus were here honoured with public worſhip; and a temple was conſecrated to each of thoſe divinities. But what rendered this place more particularly remarkable was the enmity which the inhabitants had ſworn to crocodiles, and the continual war which they waged againſt thoſe hideous reptiles. The Tentyrite

tyrite purſued the crocodile into the water, overtook him, leaped upon his back, and ran a ſtick into his mouth, with which, as with a bridle, he brought him to the ſhore, where he put him to death. In the midſt of ruins and rubbiſh, occupying a great ſpace of ground, and atteſting the grandeur and magnificence of ancient Tentyris, there is ſtill ſtanding a temple, entire, and in good preſervation. It was dedicated to Iſis; and this tutelary divinity was there worſhipped in the ſhape of a cat. This temple is in the form of an oblong ſquare, and is built of white ſtones, taken from the calcareous rocks of which the neighbouring mountains conſiſt. The façade is 132 feet and ſome inches in length. In the middle of the cornice, below the corona, is a globe reſting upon the tails of two fiſhes. The large veſtibule is ſupported by enormous columns, which are 21 feet in circumference. Their capitals are of a ſingle piece, and repreſent heads or broad faces placed oppoſite to each other, and upon a feſtooned drapery; over them are ſquare blocks, which project beyond the figures, and have ſome reſemblance to pannels. The interior of the building is divided into ſeveral apartments, the walls of which are covered with hieroglyphics and ſymbolical figures. The exterior walls are alſo charged with them. Theſe figures are very remarkable images, and ſuch as are not to be found on any other monuments of ancient Egypt. Three perſons are ſeen, who form part of an Iſiac proceſſion. Behind each of theſe figures is a row of hieroglyphics; which, if they were underſtood, would probably explain the different attributes diſtinguiſhing theſe ſeveral perſonages. The Egyptian figures which have tails are cynocephali (dog-headed) or other monkies; having a human form, with appendages aſſimilating them to animals. The flowers are probably thoſe of the lotus, or water-lily, a plant which was famous in Egypt, as a proof of the neceſſary overflowings of the Nile, and as one of the moſt common articles of ſubſiſtence of the inhabitants. The figure of Oſiris or Iſis has the head of a ſparrow-hawk; but it is impoſſible to determine whether it be a man or a woman. Its head-dreſs is compoſed of the ſun's diſk and the lunar creſcent; it holds in one hand the *thau*, or handled croſs, and in the other, a ſceptre capped with a ſection of the fruit of the Egyptian arum (arum colocaſia) one of the plants moſt in uſe for the ſuſtenance of the inhabitants of Egypt. Here is obſerved a ſceptre ſurmounted by a fleur-de-lis, adopted by the kings of France for their coat of arms. This ſeems to have been the emblem of power among ſeveral ancient nations in the Eaſt. Herodotus and Strabo relate, that the kings of Syria and Babylon formerly bore the fleur-de-lis at the end of their ſceptre. The cieling of part of this temple is painted in freſco, of the brilliant azure blue colour, with which, in fine weather, the canopy of heaven is adorned; the figures in relievo, with which this blue ground is interſperſed, have been painted of a beautiful yellow; and theſe paintings, at the expiration of ſome thouſands of years, ſtill poſſeſs a brilliancy to which our preſent colours cannot be compared, and they are ſtill as bright as if they had been recently laid on.

We have already obſerved, that the façade of this temple is more than 132 feet in length. The depth of the periſtyle is 115 feet 3 inches, and its breadth 60 feet 11 inches. The two ſides of the edifice are 254 feet 9½ inches in length; and the depth is 110 feet 11 inches. The roof of the temple is flat, and formed of very large ſtones, placed from one pillar to another, or from a wall to a pillar, or reſting upon two party-walls. Several of theſe blocks are 18 feet long, and 6 broad. Such is the deplorable change that has taken place in Egypt with regard to the arts, which had their birth here, and which had arrived at a high degree of perfection, that a number of figures have diſappeared in this wonderful monument of ingenuity, under the efforts of that deteſtation which modern barbarians have vowed to the arts, in general; and, in particular, to repreſentations of animated nature. All the figures, within their reach, are in a great meaſure deſtroyed. Several Greek and Roman copper medals and engraved ſtones, as well as other fragments of antiquity, and emeralds, are very commonly found in the ruins of Tentyris. According to the aſtronomical obſervations made by Mr. Bruce, the latitude of Dendera is determined to be 26° 10′. Sonnini's Travels in Upper and Lower Egypt.

DENDERMOND, Dermonde, *Tenermonde*, *Teneræmunda*, but at preſent generally called *Termonde*, is a town of France, in the department of the Scheldt (Eſcaut), at the confluence of the river Scheldt and Dender, which traverſes the town; 18 miles S. of Antwerp, 18 miles W. of Malines, and 18 miles N. W. of Bruſſels. N. lat. 51° 3′. Dendermond is well fortified, its environs can eaſily be laid under water, and ſome works which have lately been added, render it very ſtrong, and particularly important in time of war to facilitate or to impede the communication between Gand and Antwerp. It is the chief place of a diſtrict of the ſame name, and counts 5028 inhabitants. Its canton has an extent of 90 kiliometres, 11 communes, and a population of 18875 individuals. The whole diſtrict contains 11 cantons, 73 communes, 180,516 inhabitants, and a territorial extent of 892 kiliometres and a half. The ſoil is uncommonly fertile, producing all ſorts of corn, beſides hemp and flax. It has excellent paſtures, and is remarkable for good horſes.

DENDRANATOMY, from δενδρον, *tree*, and ανατομη, *anatomy*, a term uſed by Malpighi, and others, to expreſs the diſſection of the ligneous parts of trees and ſhrubs, in order to the examination of their ſtructure and uſes. Galen has uſed the ſame word, and taken ſome pains to diſcover ſome of the ſubjects of theſe reſearches. There is a very remarkable analogy between the parts of ſome trees, and thoſe of peculiar parts of animal bodies; and Malpighi has, with great juſtice, uſed the comparative anatomy of trees, to explain, by the formation of the galls, and other preternatural tumors on them, the puſtules and other unnatural fleſhy excreſcences on animal bodies.

DENDRITES, Dendritical. This term, derived from δενδρον, *a tree*, is applied to thoſe cryſtallizations of ſalts and other bodies that aſſume a ramified appearance. The lateral branches of the dendritically cryſtallized ſalts are generally long and ſlender, and more or leſs curved; hence they often as much reſemble feathers as vegetables, in which caſe they are generally denominated feathery or plumoſe. Some of the moſt beautiful ſpecimens of this kind of cryſtallization are exhibited by the froſt work that forms on the inſide of windows during the winter. Sal ammoniac and nitre may alſo be made to depoſit cryſtals of great beauty by ſpreading a few drops of a watery ſolution of each on the ſurface of a plate of glaſs, and allowing it to dry gradually.

Of the mineral ſubſtances, thoſe the moſt liable to this kind of cryſtallization, are native copper, ſilver, and gold, and the mixed oxyds of iron and manganeſe. The latter forms thoſe extremely delicate blackiſh brown ſprigs reſembling moſs, and the ſmaller kinds of ſea-weed by which the ſurface of many kinds of marble is variegated, and which, when imbedded in agate and chalcedony, form thoſe pretty pebbles called Mochoa ſtones. It may be obſerved by the way that they are thus called not becauſe they come from the town of Mochoa in Arabia, but from a corruption of the German term *mochſtein*, moſs-ſtone.

DENDROBIUM, in *Botany*, (from δενδρον, *a tree*, and βιος, *life*,)

life,) a genus of plants, belonging to the Orchis tribe, growing paraſitically, for the moſt part, on the trunks or branches of old trees, in tropical countries. Willd. Sp. Pl. v. 4. Swartz. Act. Holm. 1800. p. 244. Tracts on Botany, 197. Schrad. Journal, 1799, 234. t. 2. f. 1. Sw. Orchid. in Schrad. Neues Journ. v. 1. 92. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juſſ.

Gen. Ch. reformed. *Cal.* (in ſome ſpecies reverſed,) three-leaved, oblong, ſomewhat ſpreading; the two lowermoſt leaves extended at the baſe, on their under ſide, and cohering ſo as to form a pouch, bearing ſome reſemblance to a ſpur. *Cor.* Petals two, oblong, lateral; nectary a lip, of various ſhapes in different ſpecies; its baſe included in, and often connected with, the pouch of the calyx, deſtitute of a ſpur; its prominent part occaſionally concave or flat, undivided or lobed, generally more coloured than the reſt of the flower. *Stam.* Anther an hemiſpherical terminal deciduous lid, of two or four cells; maſſes of pollen two or more, globular, yellow, glutinous. *Piſt.* Germen inferior, oblong or ovate, erect, furrowed; ſtyle columnar, ſemi-cylindrical, a little incurved, concave in front; ſtigma a moiſt, ſhining, orbicular ſpot, in the fore part of the ſtyle near the top. *Peric.* Capſule oblong or ovate, with three or ſix angles or ribs, one cell and three valves, burſting between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic.

Eſſ. Ch. reformed. Calyx-leaves forming a pouch with their baſe. Lip without a ſpur. Anther vertical. Pollen globoſe. Flowers often reverſed.

* *Flowers direct.*

Sp. 1. D. *palmifolium*. Sw. (Epidendrum palmifolium; Sw. Prod. 123.) "Leaves lanceolate, broad, ribbed, each proceeding from a bulb. Flower-ſtalks radical, many-flowered." Sw. Found by Dr. Swartz in Jamaica, and known to us by the above characters only. 2. D. *Barringtoniæ*. Sw. (Epidendrum Barringtoniæ; Sm. Ic. Pict. t. 15.) Leaves elliptic-lanceolate, many-ribbed, ſeveral proceeding from each bulb. Flower-ſtalks radical, moſtly ſingle-flowered. We believe this magnificent ſpecies has never been publiſhed but by the writer of the preſent article, in the work above quoted. Dr. Swartz has taken his characters from thence, he not having met with it in Jamaica, from which iſland its roots were ſent to the late Hon. Mrs. Barrington, in whoſe fine collection at Mongewell they flowered in April, 1791. The next year the ſame ſpecies bloſſomed under Mr. Fairbairn's care at Cheſſea. The *roots* are, as in the whole genus, perennial and paraſitical; conſiſting of long, thick, round, downy branching fibres, which inſinuate themſelves into the cracks and cavities of the old rotten bark of trees. *Bulbs* expoſed, cluſtered, ovate, green, ſmooth, longitudinally furrowed and wrinkled, as large as turkey's eggs. *Leaves* three or four from the top of each bulb, a foot long, ſheathing, ſpreading, of a broad lanceolate, ſomewhat elliptical, ſhape, waved, pointed, ribbed, plaited, entire, ſmooth, of a fine green. *Flower-ſtalks* radical, few, three inches high, ſimple, ſheathed with ſcales, each bearing one, rarely two, large and very ſingular flowers, whoſe *calyx* and *petals*, each much above an inch long, are green, tipped with a tawny hue, and elliptical. *Lip* rather ſhorter than the petals, three-lobed, with a thick yellow palate; the ſide lobes ſmall, thin, acute; the central one large, fringed, orange bordered with yellow. *Style* with its lid white, bent down to the palate. In drying every part turns black. The flowers have no ſmell. 3. D. *præcox*. (Epidendrum præcox; Sm. Exot. Bot. t. 97.) Leaves lanceolate, three-ribbed; two from each bulb. Flower-ſtalks terminal, ſingle-flowered. Lip of the nectary tubular, fringed, marked with five rough lines. Found by Dr. Francis Buchanan in Upper Nepal in the Eaſt Indies, growing among moſſes on the trunks of trees or on rocks. The natives call it *Caybu ſwa*. *Bulbs* at firſt ſmall, awl-ſhaped, inveſted with ſcales; afterwards ovate or heart-ſhaped, and as large as the root of a tulip, green ſpeckled with purple. *Leaves* in pairs from the ſummit of each bulb, lanceolate, three-ribbed, ſomewhat ſtalked, coming after the *flowers*, which grow ſolitary on a little ſtalk from the top of (we believe) a diſtinct, but ſimilar, bulb, and are very large and handſome, purple; their *nectary* rolled up into a tube, its edge fringed and white, its palate marked with five parallel, rough, yellow ribs. 4. D. *humile*. (Epidendrum humile; Sm. Exot. Bot. t. 98.) Leaves ..... Flower-ſtalks radical, ſingle flowered. Lip of the nectary tubular, jagged, hairy, marked with nine elevated lines. Gathered alſo on the moſſy trunks of trees in Upper Nepal, by Dr. Buchanan, who never could find any *leaves*. Its habit is like the laſt, and probably the *bulbs* bear leaves at their ſummits, as in that. The *flower-ſtalks* however ſpring from the root. *Flowers* ſolitary, fleſh-coloured with purple ribs. *Lip* very beautifully coloured internally with yellow and crimſon, fringed alſo and hairy. The two laſt are moſt lovely plants, whoſe bulbs, if they could be procured, would prove a great acquiſition to our gardens. 5. D. *ſanguineum*. Sw. (Satyrium n. 3; Browne's Jamaica, 324. Vilcum radice bulboſâ minus, delphinii flore rubro ſpecioſo; Sloane's Jam. v. 1. 250. t. 121. f. 2.) "Leaves oblong, ſingle-ribbed, two from each bulb. Stalk terminal, with ſeveral flowers. Petals decurrent along the germen." A native of the Weſt Indies. Browne ſays it is one of the moſt beautiful of its tribe, and grows indifferently on all the trees and rocks in the low lands of Jamaica. *Bulbs* about the ſize of nutmegs, each bearing two rigid, elliptic-oblong, blunt *leaves*, with one channelled rib. *Stalks* terminal, ſolitary from between the leaves, a ſpan high, divided into a few branches, every one of which bears a purple flower, above an inch in diameter, whoſe lip is broad and crenate, variegated with yellow and purple. According to Swartz the two *petals* run down the germen, of courſe within the pouch of the *calyx*, in the form of a ſpur. 6. D. *moſchatum*. Sw. Orch. 94. (Epidendrum moſchatum; Buchanan in Symes's Emb. to Ava, t. 26. Thee-kua nee of the Birmans.) Stem creeping, marked with eight furrows. Leaves two-ranked, elliptic. Cluſters many-flowered. Petals twice as broad as the calyx. Lip entire. Grows on trees in the Eaſt Indian kingdom of Ava. The leafy *branches* are a foot long, with eight furrows, like the main ſtem. *Leaves* rigid, ſmooth, elliptic-oblong, obtuſe, ſpreading in two ranks. *Cluſters* ſpreading in an oppoſite direction to the branches; their ſtalks round and even. *Flowers* about ſix in each cluſter, large, very fragrant, yellow with a purple ſpot on each ſide of the nectary. Buchanan. 7. D. *Myoſurus*. Sw. (Epidendrum Myoſurus; Forſt. Prod. 60.) "Leaves linear, ſomewhat lanceolate, channelled, ſlightly emarginate. Flower-ſtalks naked. Spike filiform, drooping." Sw. A native of the Society iſlands in the South ſea. Forſter. 8. D. *utricularioides*. Sw. (Epidendrum utricularioides; Sw. Prod. 122.) "Leaves lanceolate, lineated, flat, ſtalk panicled. Petals united by their baſes into a very ſhort ſpur, beneath the great inverſely heart-ſhaped lip." Sw. Found by Dr. Swartz in Jamaica and Hiſpaniola, and his ſpecific character is all the information we have concerning it. 9. D. *teſticulatum*. Sw. (Epidendrum ſatyrioides; Sw. Prod. 123.) "Leaves cylindrical, ſomewhat tapering. Flower-ſtalk nearly ſimple. Flowers with two globoſe ſwellings at the baſe in front." Sw. A

native of Hiſpaniola. 10. D. *punctatum*. Sm. Exot. Bot. t. 12. Leaves radical, very ſhort, imbricated. Spike many-flowered. Lip three-lobed, acute, downy. Sent by Dr. White from the neighbourhood of Port Jackſon, New South Wales. *Stems* ſeveral, two or three feet high, unbranched, round, purple, clothed with a few ſtraggling ſcales only, and bearing ſix or eight ſhort, imbricated, ovate, fleſhy *leaves* at the baſe. Each ſtem terminates in a long ſimple bracteated *ſpike*, or rather *cluſter*, of very numerous and handſome purple flowers, dotted all over with red ſpecks, and their germens are beſprinkled with purple glands. The *calyx-leaves* and *petals* are lanceolate and acute. *Lip* ſcarcely equal to them in length, deeply three-lobed, yellow and downy above towards the baſe. 11. D. *corniculatum*. Sw. (Epidendrum corniculatum; Sw. Prod. 123.) "Stem very ſhort. Leaf ſolitary, oblong, ſomewhat wedge ſhaped, ſlightly ſtalked. Flower ſolitary, with a curved point." Sw. A native of Jamaica. 12. D *lanceolatum*. Sw. (Epidendrum Lanceola; Sw. Prod. 123.) "Stem very ſhort. Leaf ſolitary, lanceolate, ſtalked. Stalks two-flowered." Sw. This minute ſpecies forms little tufts, each plant conſiſting of a *ſtem* about half an inch high, bearing at its ſummit one narrow, lanceolate, ſtalked, ſmooth, pale-green, ſtraight leaf, ſcarcely two inches long, and by its ſide a ſlender, ſhorter flower-ſtalk, on which ſtand two little pale bracteated *flowers*. It grows in Jamaica, from whence we have received it through Dr. Swartz's hands. 13. D. *ſertularioides*. Sw. (Epidendrum ſertularioides; Sw. Prod. 122) "Stem ſlender, creeping. Branches erect, very ſhort, ſingle-leaved. Leaves lanceolate, ſomewhat ſtalked. Flowers ſolitary." Sw. A native of Jamaica. 14. D. *racemiflorum*. Sw. (Epidendrum. racemiflorum; Sw. Prod. 125.) Stem elongated, erect, ſheathed. Leaf ſolitary, elliptical, ſtalked. Cluſter taller than the leaf. Flowers leaning to one ſide, pointed, quadrangular. A native of Jamaica. Dr. Swartz. It has ſomewhat of the aſpect of the Linnæan *Ophrys monophyllos*, but with fewer flowers in the cluſter, and thoſe flowers are alſo larger. The *leaf* is obtuſe, with one principal rib, and many ſmaller ones. *Stem* inveſted with a few long, tubular, brown, membranous ſcales. 15. D. *alpeſtre*. Sw. (Epidendrum alpeſtre; Sw. Prod. 125.) "Stem elongated. Leaf ſolitary, ovato-lanceolate. Cluſters looſe. Angles of the capſule muricated." Sw. A native of Hiſpaniola. 16. D. *laxum*. Sw. (Epidendrum laxum; Sw. Prod. 125.) "Stem elongated. Leaf ſolitary, oblong, pointed. Cluſters looſe. Capſules naked." Sw. A native of Jamaica. Dr. Swartz ſuſpects Plumier's Helleborine ophiogloſſo ſimilis, Ic. t. 176. f. 3, may be this ſpecies, though quoted by Linnæus for his Epidendrum ophiogloſſoides, which is Stelis ophiogloſſoides of Swartz, a very different plant. 17 D. *ruſcifolium*. Sw. (Epidendrum ruſcifolium; Linn. Sp. Pl. 1353. Jacq. Amer. 226. t. 133. f. 3.) "Stem elongated. Leaf ſolitary, ovato-lanceolate. Flowers cluſtered in the boſom of the leaf." Sw. Found in Martinico. *Root* fibrous. *Stem* ſolitary, ſimple, ſtraight, ſcarcely a ſpan high, bearing one pale terminal *leaf*, of an ovato-lanceolate, pointed form, with many ribs, from the inſertion of whoſe ſtalk ſprings a little tuft of greeniſh white flowers.

* * *Flowers reverſed.*

18. D. *biflorum*. Sw. (Epidendrum biflorum; Forſt. Prod. 60.) "Stem round, ſimple. Leaves in two ranks, linear-lanceolate, flat. Flower-ſtalks very ſhort, in pairs, oppoſite to the leaves, proceeding from the baſe of their ſheaths." Sw. Native of the Society iſlands, in the South ſea. The *ſtem* bears many *leaves*, whoſe ſheaths are perforated by a pair of flower-ſtalks, each bearing a ſingle flower. Sw. 19. D. *anceps*. Sw. "Stem two-edged, ſimple. Leaves in two ranks, lancet-ſhaped, flat. Flower-ſtalks very ſhort, in pairs from the baſe of the ſheaths." Sw. A native of the Eaſt Indies, known to us only by the above characters. 20. D. *moniliforme*. Sw. (Epidendrum moniliforme; Linn. Sp. Pl. 1352. E. monile; Thunb. Jap. 30. Fu Ran; Kæmpf. Exot. 864, cum ic.) Stem round, ſimple, jointed. Leaves linear-lanceolate, acute. Flowers on terminal, elongated, divaricated ſtalks. Spur rounded. Common upon trees, rocks, and walls in Japan, where it is uſual to hang up bunches of this plant in the houſes, in which ſituation it will, according to Kæmpfer, bear flowers and ſeed; and though it bloſſoms no more, it will retain life for ſeveral years. The *roots* creep by means of ſcyons. *Stems* cluſtered, erect, ſimple, of many ſtriated joints. *Leaves* coming after the flowers, linear-lanceolate, acute, chiefly about the tops of ſome of the ſtems. *Flowers* from the ſummits of the leafleſs ſtems, two, three, or more, together, on ſpreading ſtalks about an inch long. They are white or bluſh-coloured, with a thick rounded baſe or ſpur. The lip is ſpotted with purple. Kæmpf. Thunb. 21. D. *crumenatum*. Sw. (Angræcum crumenatum; Rumph. Amb. v. 6. 105. t. 47. f. 2.) "Stem ſomewhat branched, ſlightly compreſſed, tuberous at the baſe. Leaves ovato-lanceolate. Cluſters erect. Flowers in alternate diſtant pairs. Spur acute." Sw. Native of Java; Sw. Amboina; Rumphius. This ſpecies is but imperfectly known to us, though we have ſeveral from Dr. Buchanan, and there are ſome in Rumphius, nearly related to it, the preciſe determination of which muſt be reſerved for ſome future opportunity. Their *flowers* are generally large and handſome, often in pairs, with a conſiderably elongated ſpur-like baſe. *Stems* clothed with alternate *leaves*, of a coriaceous texture whith numerous ribs. 22. D. *polyſtachyon*. Sw. (Epidendrum minutum; Aubl. Guian. v. 2. 824. Heleborine ramoſa, floribus minimis luteis; Plum. Ic. 180. t. 185. f. 1.) "Leaves nearly radical, elliptic-lanceolate. Stem two-edged. Spikes numerous, alternate, all leaning one way." Sw. Native of Guiana, the Weſt Indies, and, according to Swartz, of Africa and the Eaſt Indies. *Root* of many thick, juicy, ſimple fibres. *Stem* ſolitary, clothed, at the very baſe only, with ſeveral broad-lanceolate, ſpreading, rigid, ribbed *leaves*. *Flowers* terminating the ſtem, which is otherwiſe ſimple, in ſeveral alternate, looſe, roughiſh ſpikes. *Bracteas* minute. *Petals* ſmall, yellowiſh. *Germen* long. *Capſules* elliptical. The flowers in Plumier's plate are very incorrect. 23. D. *criſpatum*. Sw. (Epidendrum criſpatum; Forſt. Prod. 60.) "Stem branched, wand-like. Leaves thread-ſhaped, ſomewhat incurved. Cluſters lateral, ſimple." Sw. Found in the Society iſles of the South ſea. The middle ſegment of the lip is revolute, undulated and crenate. Forſter. 24. D. *javanicum*. Sw. "Stem throwing out roots. Leaves ſtalked, erect, broad-lanceolate, obtuſe. Stalks many-flowered, from the baſe of the ſheathing footſtalks." Sw. A native of Java. 25. D. *ſpecioſum*. Sm. Exot. Bot. v. 1. 17. t. 10. Stem ſimple. Leaves nearly radical, elliptic-oblong. Cluſter ſolitary, terminal, many flowered. Lip three-lobed. Grows on rocks and trees about Port Jackſon, New South Wales. *Stem* ſhort and thick. *Leaves* almoſt entirely radical, from ſix to twelve inches long, more or leſs recurved, oblong or ſomewhat elliptical, ribbed, very tough and rigid. *Cluſter* ſolitary, on a terminal, ſcaly ſtalk, ſimple, a foot or more in length, conſiſting of a great number of alternate or ſcattered flowers, which are large and handſome, variegated with white, yellow, and pink, the lip dotted with purple. *Capſule* obovate, large. 26. D. *linguiforme*. Sm. Exot. Bot. v. 1. 19. t. 11. Stem creeping. Leaves ſeſſile, obo-

vate ſmooth, fleſhy. Cluſters from the baſe of the leaves. Lip revolute. Grows on rocks along the ſea-ſhore at Port-Jackſon, New South Wales. *Stems* branched, creeping, with very long, thick, fibrous roots. *Leaves* alternate, ſcarcely an inch long, ſeſſile, obovate or elliptical, ſmooth, extremely thick and juicy, convex beneath, furrowed above. *Stipula* ſolitary, ſheathing, membranous, very large. *Cluſters* ſolitary from each ſtipula at the baſe of the leaf, erect, about a finger's length, inveſted with a double ſheath of their own in the lower part, ſlender above, of ſix or more very elegant flowers. The *petals* and *calyx-leaves* are upright, linear, acute, cream-coloured. *Pouch* yellowiſh, ſhort. *Lip* narrow, acute, revolute, ſlightly three-lobed, blue near the baſe, yellowiſh and furrowed towards the extremity. 27. D. *pygmæum*. Stem creeeping, bulbiferous. Leaves nearly ſeſſile, elliptical, downy, coriaceous, ſolitary from each bulb. Cluſters .... Gathered on moſſy rocks and trees in New Zealand, by Mr. Archibald Menzies, F.L.S. This is but half the ſize of the laſt, with which it agrees ſo nearly in habit, that though its flowers are unknown, we ſcruple not to refer it hither. *Stems* thread-ſhaped, ſlender. *Leaves* alternate, on very ſhort footſtalks, elliptical, obtuſe, revolute, coriaceous rather than fleſhy; ribbed and roughiſh beneath; clothed above with ſhort, prominent, downy hairs. Each footſtalk proceeds from a little round bulb, like a ring, ſmooth and ſhining, yellowiſh, and much wrinkled in a dry ſtate, but apparently very ſucculent when freſh. 28. D. *reptans*. Sw. "Stem creeping, bulbiferous. Leaves ovate, in pairs from each bulb. Flower-ſtalks radical." Sw. Found in the iſland of Mauritius. Of this we know nothing but the above character of Dr. Swartz, who quotes in Schrader's Journal, 215, (where he originally made it a *Cymbidium*,) the Tjſeroutecka-maravara, Rheede Hort. Mal. v. 12. 45. t. 23, but with a mark of doubt. The plant there figured is cloſely allied to our laſt ſpecies, but its leaves are larger, ſmooth, emarginate, and their bulbs rather elliptical than annular. Each bulb bears but one leaf, which circumſtance does not accord with Dr. Swartz's ſpecific character. 29. D. *galeatum*. Sw. "Stem creeping. Branches ſheathed, ſingle-leaved. Leaves broad-lanceolate, obtuſe. Cluſters ſolitary, many-flowered, ſhorter than the leaves. Flowers conical, incurved, helmet-ſhaped." Sw. Gathered at Sierra Leone, Africa, by Dr. Adam Afzelius, as well as the three following, all known to us merely by the characters given in Dr. Swartz's work above quoted. 30. D. *pumilum*. "Stem creeping, thread-ſhaped, bulbiferous. Leaves oblong, ſolitary from each bulb. Flower-ſtalks from the baſe of the bulbs, very ſlender, elongated; zig-zag at their ſummits." Sw. 31. D. *roſeum*. "Stem leafleſs, upright, clothed with ovato-lanceolate membranous ſheaths. Cluſter terminal. Flowers conical, ſomewhat deltoid; lip ſpatulate, minutely crenate." Sw. 32. D. *paniculatum*. "Stem clothed in its lower part with oblong, obtuſe, emarginate leaves; in its upper two-edged and ſheathed. Spikelets thread-ſhaped, panicled, terminal. Flowers crowded, minute." Sw.

Dr. Swartz conjectures the *Epidendrum carinatum*, Linn. (Bontiana luzonica; Petiv. Gazoph. t. 44. f. 10.) may be of this genus, which, as far as can be gueſſed from Petiver's incomplete figure, is probable. Linnæus, who truſted to this figure alone, ſeems to have taken the bulbs for leaves.

Alſo the following:

Epidendrum graminifolium; Linn. known only by Plumier's Ic. t. 176. f. 1.

Epidendrum concretum; Jacq. Amer. 228.

Ceraia ſimpliciſſima; Loureir. Cochinch. 518.

Flos lyncis; Hernand. Mex. 266, a magnificent plant apparently moſt akin to our ſecond ſpecies.

The whole genus *Maxillaria* of the Flora Peruviana. See its Prodromus, t. 25.

With ſeveral ſpecies of *Angræcum* in Rumphius, to which we have already alluded; ſee his v. 6. t. 45—51.

DENDROMETER, (from δενδρον, *a tree*, and μετρεω, *I meaſure*,) an inſtrument for meaſuring trees. The firſt inſtrument for the purpoſe of meaſuring the trunk, the branches, and the height of a tree, without actually touching the tree, was contrived, not many years ago, by Meſſrs. Duncombe and Whittel, who called it the *dendrometer*, and obtained a patent for the excluſive ſale of it. Since this inſtrument ſerves to meaſure trees from a determinate diſtance, other inſtruments, contrived ſubſequent to it, for the purpoſe of meaſuring the ſizes as well as the diſtances of objects in general, though not particularly intended for the menſuration of trees, have likewiſe been called *dendrometers*. The principle of every one of thoſe inſtruments is, that a part of the inſtrument forms a baſe of known dimenſions, and the angle at each extremity of this baſe being meaſured with great accuracy, the diſtance of the object may be obtained by means of an eaſy calculation, or from a table. The diſtance being thus aſcertained, the ſize of the object will afterwards be eaſily determined from the angle which it is found to ſubtend. We ſhall now in the firſt place deſcribe Meſſrs. Duncombe and Whittel's original dendrometer; ſecondly, we ſhall deſcribe another inſtrument lately contrived for the purpoſe of meaſuring trees but by immediate contact; and ſhall, laſtly, give a general idea of the other inſtruments for meaſuring diſtances, &c. which have likewiſe obtained the name of *dendrometers*.

"Meſſrs. Duncombe and Whittel's dendrometer conſiſts of a ſemicircle A, (*Plate* VI. *Surveying*, *fig.* 7.) divided into two quadrants, and graduated from the middle. Upon the diameter B, there hangs a plummet, L, for fixing the inſtrument in a vertical poſition. There is alſo a chord, D, parallel to the diameter, and a radius, E, paſſing at right angles through the diameter and chord. From a point on the radius, hangs an altimeter C, between the chord and diameter, to which is affixed a ſmall ſemicircle G, and a ſcrew to confine it in any poſition. The altimeter, which is contrived to form the ſame angle with the radius of the inſtrument as the tree forms with the horizon, is divided from its centre both ways into 40 equal parts; and theſe parts are again ſubdivided into halves and quarters. Upon the ſmall ſemicircle, G, on which is accounted the quantity of the angle made by the altimeter and radius, are expreſſed degrees from 60 to 120; being 30 on each quadrant. The radius is numbered with the ſame ſcale of diviſions as the altimeter. There is alſo a nonius to the ſmall ſemicircle, which ſhews the quantity of an angle to every five minutes. On the back of this inſtrument the ſtock M, (*fig.* 8.) of the ſliding-piece is confined to the axis N, which moves concentrically paralliel to the elevation index, F, (*fig.* 7.) on the oppoſite ſide, to which it is affixed. This index is numbered by a ſcale of equal diviſions with the altimeter and radius. At the end of the index is a nonius, by which the angles of elevation above or of depreſſion below the horizon, meaſured upon the ſemicircle of the inſtrument, are determined to every five minutes. There is alſo a groove in the radius, that ſlides acroſs the axis by means of a ſcrew, I, working between the chord and ſemicircle of the inſtrument; and this ſcrew is turned by the key O. Upon the ſtock, M, (*fig.* 8.) is a ſliding piece, P, that always acts at right-angles with the altimeter, by means of a groove in the latter. To the ſhank of the ſliding piece is affixed a moveable limb, Q, which

forms the ſame angle with the altimeter as the bough forms with the body, or trunk, of the tree. This limb may be of any convenient length, divided into equal parts of the ſame ſcale with all the foregoing diviſions."

"At the extremity of the fixed axis, on a centre, an index, R, with teleſcopic ſights, works horizontally upon the moveable limb of the ſliding piece. Upon this horizontal index, R, may be fixed a ſmall quadrant, T, deſcribed with any convenient radius from the centre, on which the index moves, and divided into 90°; beginning at a right line drawn from the centre at right angles with the fiducial edge of the ſaid index; and upon the extremity of the axis is a nonius, whereby to determine the quantity of an angle upon the quadrant to every five minutes. There are alſo two ſmall circular arches, S, S, ſerving to keep the ſights in a parallel poſition, each containing an equal number of degrees. Upon theſe arches is meaſured the angle, ſubtending a ſide equal to the difference of the altitudes of the obſerved objects, above the plane of the horizon, and whoſe baſe is the neareſt diſtance between the perpendiculars, in which thoſe objects are ſituated. The *dendrometer* is fitted to a theodolite, and may be uſed either with or without it, as occaſion requires."

"The principal uſe of this inſtrument is for meaſuring the length and diameter of any tree, perpendicular, or oblique, to an horizontal plane, or in any ſituation of the plane on which it reſts, or of any figure, whether regular or irregular, and alſo the length and diameter of the boughs, by mere inſpection; and the inventors of it have calculated tables, annexed to their account of the inſtrument itſelf, by the help of which the quantity of timber in any tree is obtained without calculation, or the uſe of the ſliding rule.

"The inſtrument is rectified by ſetting it in a perpendicular poſition, by means of the plummet, and ſcrewing it to the ſtaff; then the altimeter is placed in the exact poſition of the tree, whether perpendicular, reclining, or inclining, and is ſcrewed faſt. If the tree ſtands on level ground, the horizontal diſtance from the tree to the axis of the inſtrument is meaſured with a tape line, and the radius is moved with the key, till that diſtance be cut upon it by the inſide of the diameter: but if the ground be ſlanting, the diſtance from the tree to the inſtrument is meaſured, and the elevation index is moved, till the point of the tree, from which the diſtance was meaſured, is ſeen through the ſights, and there ſcrewed faſt; and the radius is moved backwards or forwards with the key, till this diſtance is cut upon the elevation index by the perpendicular line of the altimeter; and the horizontal line will be marked upon the radius by the inſide of the diameter. In order to obtain the length of the tree, the elevation index is firſt moved downwards, till the bottom of the tree, cut by the horizontal wires, is obſerved through the ſights, and the feet and inches marked by the index upon the altimeter below the point of ſight, or horizontal line, are noted down: then the index is moved upwards, till the part which you would meaſure, cut by the horizontal wires, is ſeen, and the feet and inches marked on the altimeter, above the point of ſight, are noted: theſe two quantities added together, give the exact length of the tree, which is inſerted in a field-book. For the girth of the tree, the circumference in that part where the horizontal diſtance was taken, is meaſured with the tape line; and a ſixth part of this circumference is added to the diſtance on the radius, which was before cut by the inſide of the diameter, becauſe the tape-line, in taking the diſtance, cannot be applied to the centre of the body of the tree; then the elevation index is lowered to that part of the tree, of which the diameter is to be taken, and is ſcrewed faſt. Set the moveable limb of the ſliding-piece quite ſtraight; and the edge of the horizontal index upon the firſt diviſion of it. Turn the whole inſtrument about to the left hand, till you ſee, through the ſights, the left ſide of the tree cut exactly by the perpendicular wires; then the inſtrument being fixed, move the ſights only upon the ſliding-piece, till you ſee the right ſide of the tree, cut alſo by the perpendicular wires, and you will find the true diameter, marked by the horizontal index upon the ſliding-piece, which is to be entered in a diſtinct column of the field-book.

"For the boughs: let the diſtance on the radius be now reduced to its former quantity, and the elevation index moved upwards, till the bough is ſeen through the ſights, and ſcrewed faſt. Set the moveable part of the ſliding piece in a poſition parallel to the bough, and the edge of the horizontal index on the firſt diviſion of it. Turn the whole inſtrument about, till you ſee, through the ſights, the ſhoot of the bough, cloſe to the trunk cut by the perpendicular wires; then move the ſights, till you ſee the other end of the bough cut by the ſaid wires, and note the feet and inches marked by the horizontal index on the moveable limb of the ſliding piece, which will give the true length of the bough to be inſerted in the field-book. And the girth of the bough may be obtained, by directing the ſights to that part of it, whoſe girth is deſired; then by moving the elevation index downwards, till you ſee the under-ſide of the bough cut by the horizontal wires, and there noting the feet and inches marked by the ſaid index on the altimeter; after which let the elevation index be moved upwards, till the upper ſide of the bough, cut by the horizontal wires, is ſeen; the feet and inches marked upon the altimeter are to be noted as before: the former quantity ſubtracted from the latter, will give the true diameter of the bough, which is entered in the field-book. The true ſolidity, both of the body of the tree, and of the boughs, may be found from the diameter and lengths, in tables calculated for this purpoſe.

"The dendrometer, fitted to a theodolite, may be applied to the meaſuring of heights and diſtances of objects acceſſible or inacceſſible, whether ſituated in planes parallel, or oblique, to the plane in which the inſtrument is placed. It may be alſo uſed for taking all angles, whether vertical, horizontal, or oblique, in any poſition of the planes in which they are formed; and thus for facilitating the practical operations of engineering, land-ſurveying, levelling, mining, &c. and for performing the various caſes of plane trigonometry, without calculation; of which the inventors have ſubjoined a variety of examples to their account of the inſtrument in their treatiſe upon the *Dendrometer*."

Notwithſtanding the oſtenſible extenſive application of this inſtrument, it does not appear that the uſe of it has been generally adopted, which may be principally attributed to its complicated conſtruction.

The 25th volume of the Tranſactions of the Society for the encouragement of Arts, Manufactures, and Commerce, contains a very uſeful and ſimple machine for the meaſurement of the girths of trees, to which the inventor, Mr. James Broad, gives the name of *Gauge*, or *Meaſure for Timber*, but which in fact is a dendrometer in the ſtrict ſenſe of the word, and it therefore deſerves a place in the preſent article. This inſtrument is repreſented in *Plate* III. *Surveying*, *fig.* 9. *a a*, *a a*, Mr. Broad ſays, are two long pieces of well-ſeaſoned wood, joined near the middle by a pin, *b*, going through them, forming an axis on which they move: *c*, *c*, are two pieces of braſs ſcrewed near the upper ends, on the ſides oppoſite to each other, and projecting over to form the meaſuring points: *d*, is the index faſtened to one of the pieces of wood at *e*, and moving freely under a ſmall bar at *f*:

g, *g*,

g, *g*, are ſcrews with nuts, placed in the middle of the long ſlits of the two arms, to wedge them open, whereby the vibration is deſtroyed, and the arms, though light, are rendered ſtiff: *h*, *h*, *h*, *h*, are ſcrews and nuts, to prevent the arms from ſplitting. With reſpect to the general conſtruction, uſe, and improvements that may be made to it, Mr. Broad expreſſes himſelf in the following manner.

"The inſtrument is compoſed of two ſtraight pieces of well-ſeaſoned deal, about 13 feet long, joined together by a pin going through them, on which they are moveable; but neither the length nor thickneſs is of any particular conſequence, as by following the directions hereafter given, they may be made of any ſize. A little way from the large end is a braſs limb, I call the index, on which are engraven figures denoting the quarter-girth in feet and inches. To uſe this inſtrument, it is only neceſſary to take hold of the large end, and apply the other to that part of the tree where you wiſh to know the girth, opening it ſo wide as juſt to touch at the ſame time both ſides of it, without ſtraining it, keeping the graduated ſide of the index uppermoſt, on which the greater girth will be ſhewn, after allowing for the bark, by the inner edge of the braſs on the right-hand leg. An operation ſo eaſy and ſimple, that a perſon of the meaneſt capacity might meaſure a great number of trees in a day.

"For taking the height of a tree, I would recommend deal rods of ſeven feet long, made ſo as to fit into ferrils at the end of each other, tapering all the way in the ſame manner as a fiſhing-rod. A ſet of five of them with feet marked on them, would enable a man quickly to meaſure a tree of more than 40 feet high, as he would be able to reach himſelf about ſeven feet.

"The improvements it is capable of, are, making a joint in the arch or ſcale, to enable it to ſhut up, (when the legs are cloſed) towards the centre, which would make it eaſier to carry. Secondly, as it ſometimes happens that ſtanding timber is ſold without any allowance for bark, and at other times with a leſs allowance than one inch in 13, two other ſcales on the index might be added in ſuch caſes, one without any allowance, and the other to allow as might be agreed on. I would have added theſe, but thought the ſociety would rather ſee it in the ſtate in which it has been tried on a large ſurvey, as any artiſt can with great eaſe add whatever ſcale he pleaſes. The preſent ſcale allows one inch in 13 for bark, and is calculated on the following data. The diameter of a circle, whoſe quarter-circumference is 26 inches, is 33.96 inches. The diameter of a circle, whoſe quarter-girth is $6\frac{1}{2}$ inches, is 8.27 inches. To graduate the ſcale, the inſtrument is opened ſo as to take in at the ſmall end between the touching points 8.27 inches, and a mark is made on the arch to denote 6 inches quarter-girth; it is then opened ſo as to take in 33.96 inches, and another mark is then made on the arch, to denote 2 feet quarter-girth; (theſe marks are made cloſe to the inner edge of the braſs on the right-hand limb:) the ſpace between them is then divided into 18 parts, which repreſent inches, and are again divided into halves, for half-inches; if any notice is to be taken of quarter-inches, the eye will eaſily make a farther deciſion."

The methods of determining the diſtances and ſizes of objects placed at a diſtance from the obſerver, depend entirely upon trigonometrical principles; and thoſe methods for effecting that purpoſe, which ſeem to differ from trigonometrical principles, will upon examination be found to be nothing more than trigonometrical methods abridged or diſguiſed. The general principle upon which all the operations of plane trigonometry depend, is to find out three of the ſix parts of a triangle, when the other three are known; (the ſix parts being the three ſides and the three angles;) excepting, however, when the three angles are given; for in this caſe the proportion only of the three ſides may be found; but not their actual lengths.

When an inacceſſible diſtance is to be determined by trigonometry, the method is to meaſure a line or baſe upon any convenient place, and to obſerve the angles which the imaginary lines, ſuppoſed to be drawn from the extremities of that baſe line to a point or object at the extremity of the diſtance ſought, make with the baſe; for in that caſe we have two angles, and one ſide of a triangle, whence we find by calculation the lengths of the other ſides, one of which is the diſtance ſought. If an object of any known dimenſions be ſituated at the extremity of the diſtance ſought, that diſtance may then be determined without the neceſſity of aſſuming a baſe line upon the place of obſervation; for in that caſe, the object itſelf will be ſuppoſed to form the baſe of an iſoſceles, or of a right-angled triangle; and it will be only neceſſary to meaſure the angle which that object ſubtends at the place of obſervation. The diſtance of an object being known, the ſize of the object may be eaſily determined by only meaſuring the angle which it ſubtends. See TRIGONOMETRY.

Now the dendrometers for meaſuring diſtances from a ſingle ſtation, are ſo conſtructed as to have a line of a determinate length within themſelves, which ſerves as a baſe line, and two divided circular arches, or ſome other contrivance by which the angle which the direction of a diſtant object makes with that baſe line at each extremity of it, may be meaſured. But as ſuch inſtruments cannot be made of an inconvenient large ſize, the baſe line which they contain is but ſhort, and the error of the calculation is greater when the baſe line is ſhorter, and *vice verſâ*; whence ſuch inſtruments ſeldom furniſh a reſult ſufficiently exact, at leaſt for certain purpoſes.

The moſt complete inſtruments of this kind are furniſhed with two or more ſpeculums, (ſomewhat in the manner of Hadley's quadrant,) for meaſuring the difference of the angles at once. Upon this plan ſeveral inſtruments have been contrived and offered to the public by various writers. One of the moſt promiſing, though not the moſt compact, is deſcribed in "Gower's Supplement to the Practical Seamanſhip." But as we are not acquainted with the conſtruction of any inſtrument of this kind, that is quite free from ſtrong objections, we ſhall only ſubjoin a general idea of the principles upon which ſuch an inſtrument may be conſtructed; for the uſe of thoſe perſons who may be deſirous of employing their thoughts upon the poſſible improvements of that conſtruction.

The following plans are ſuggeſted by William Pitt, eſq. in the ſecond volume of the Repertory of Arts; which, he ſays, may perhaps be otherwiſe varied and improved.

"O, (*fig.* 10.) is the object, whoſe diſtance is required. A B C D E is the inſtrument *in plano*; B C a teleſcope placed exactly parallel to the ſide A E. C E an arch of a circle whoſe centre is at A, accurately divided from E, in degrees, &c. A D is an index, moveable on the centre A, with a nonius at the end D, graduated to apply to the diviſions of the arch; alſo with a teleſcope, to enable the obſerver to diſcriminate the object, or any particular part, or ſide, thereof, the more accurately. The whole ſhould be mounted on three legs in the manner of a plane-table or theodolite, and furniſhed with ſpirit levels, to adjuſt it to an horizontal poſition. The inſtrument being placed in ſuch poſition, the teleſcope B C muſt be brought upon the object O, or rather upon ſome particular point or ſide thereof; when,

when, being there faſtened, the index A D muſt be moved, till its teleſcope exactly ſtrikes the ſame point of the object; then the diviſions on the arch E D, mark out the angle D A E, which will be exactly equal to the angle B O A. And the ſide B A being already known, the diſtance B O, or A O, may be eaſily determined two different ways; *viz.* 1ſt, by ſuppoſing the triangle B O A to be an iſoſceles triangle; or, 2dly, by ſuppoſing the triangle A B O right-angled at B. The accuracy of ſuch an inſtrument does, *cæteris paribus*, much depend upon the length of the line A B.

"The conſtruction of a ſimilar inſtrument, on the principles of Hadley's quadrant, for naval obſervations, would alſo doubtleſs be an acceptable object in navigation, by enabling the mariner to aſcertain the diſtances of ſhips, capes, and other objects, at a ſingle obſervation; and that perhaps with greater accuracy than can be done by any method now in uſe.

"For this purpoſe, the following conſtruction is propoſed. A B C D, (*fig.* 11.) repreſents the inſtrument *in plano*. O is the object whoſe diſtance is required. At A, at C, at D, and at 3, are to be fixed ſpeculums, properly framed and fitted; that at 3 having only its lower part quickſilvered, the upper part being left tranſparent, to view the object; the ſpeculum at A being fixed obliquely, ſo that a line A 1, drawn perpendicular to its ſurface, may biſect the angle B A C in equal parts; that at C being perpendicular to the line C 2; thoſe at E, and at 3, being perpendicular to the index E 3; and that at E being furniſhed with a ſight. The arch D C is to be divided from D, and the motion of the index is to be meaſured as before by a nonius. And as the length of the line A E would tend to the perfection of the inſtrument, it may be conſtructed ſo as to fold up in the middle, on the line C 2, into leſs compaſs when not in uſe. The inſtrument may be adjuſted for uſe, by holding up a ſtaff at a diſtance, whoſe length is exactly equal to the line A E.

"To make an obſervation by this inſtrument, it being previouſly properly adjuſted, the eye is to be applied at the ſight in the ſpeculum E, and the face turned towards the object; when the object being received on the ſpeculum A, is reflected into that at C, and again into that at E, and that at 3 on the index; the index being then moved till the reflected object, in the ſpeculum at 3, exactly coincides with the real object in the tranſparent part of the glaſs. Then the diviſions on the arch D 3, ſubdivided by the nonius, will meaſure the angle D E 3 = A O E; from which the diſtance of O may be determined as before."

When a ſtraight line of at leaſt 10 or 20 feet, may be meaſured at the ſtation, where the obſerver is ſituated, and in the direction of a diſtant object; the ſize and diſtance of that object may be determined by the uſe of a moſt ſimple inſtrument; namely, a teleſcope furniſhed with a micrometer, and thus trees and other objects may be meaſured in a manner extremely commodious and ſufficiently accurate. The problems neceſſary for this purpoſe, as given by Mr. Cavallo in the deſcription of his "Teleſcopical Mother-of-Pearl Micrometer," will be found under the article MICROMETER.

DENDROPHORIA, formed of δενδρον, *tree*, and φερω, I *bear*, in *Antiquity*, the carrying of one or more trees, in ceremony, through a city, at certain feaſts, and in honour of certain deities.

The dendrophoria was performed at the ſacrifices of Bacchus, Cybele, and the god Sylvanus. Arnobius, lib. v. makes mention of that performed in the ſacrifices of the mother of the gods. It conſiſted in carrying a pine in proceſſion through the city; which pine was afterwards planted in memory of that under which Atys, the favourite of this goddeſs, mutilated himſelf. The branches of this tree they crowned, in memory of Cybele's doing the ſame; and they covered its trunk with wool, becauſe the goddeſs covered Atys's breaſt with the ſame matter.

The perſons who performed the office of carrying the tree were called dendrophori.

In the Roman hiſtory we find mention made of a company or college of dendrophori, who attended the army; and the critics have laboured much to aſſign their office. Some hold, that they hewed and faſhioned the wood for the tents: others, that they provided the wood neceſſary for the military works, machines of war, &c. Salmaſius, in his notes to the life of Caracalla by Spartian, owns this to be the general opinion of all the learned men of his time; but aſſures us, that they were all miſtaken, and that the dendrophori of the army were the ſame with thoſe of the feaſts and ſacrifices.

DENEB, an Arabic term, ſignifying tail; uſed by aſtronomers as a denomination of ſeveral fixed ſtars.

Thus deneb elecet ſignifies the bright ſtar in the Lion's tail; deneb adigege, that in the Swan's tail, &c.

DENEB, or ALDENEB, *Alcahil*, in the *Writings of the Arabian Phyſicians*, the name of the equiſetum or horſe-tail; there is, however, no great dependence to be had on what authors ſay of this plant.

DENE'E, in *Geography*, a ſmall town of France, in the department of Maine and Loire; 9 miles S. of Angers.

DENEITER, a town of America, in the ſtate of New York, and county of Chenango, containing 310 inhabitants.

DENEUVRE, a ſmall town of France, in the department of the Meurthe; 3 miles S.E. of Baccarat, and 12 miles S.E. of Luneville. It is ſituated on the river Meurthe.

DENEZ'E, a town of France, in the department of the Maine and Loire; 8 miles W. of Saumur.

DENFIELD, a town of America, in New York, and county of Oneida, containing 1039 inhabitants.

DENGLING, a town of Germany, in the circle of Bavaria, and archbiſhopric of Saltzburg; 20 miles N.W. of Saltzburg.

DENGUIN, a ſmall town of France, in the department of the Lower Pyrenées; 3 miles W. of Leſcar.

DENHAM, Sir JOHN, in *Biography*, a poet who has obtained celebrity, chiefly, if not entirely, on account of a few happy couplets that have been quoted a thouſand times as illuſtrative of high poetic excellence. He was born at Dublin in 1615; his father, ſir John, being at the time of the ſon's birth, chief baron of the exchequer in Ireland; an office which he did not long enjoy, as he returned to England in 1617. The young man having laid the foundation of a learned education at a grammar-ſchool, was, at the age of ſixteen, entered a gentleman commoner in Trinity college, Oxford. As a ſtudent he did not by any means diſtinguiſh himſelf, but nevertheleſs obtained his bachelor's degree, and removed to Lincoln's-Inn to ſtudy the law. At college he had acquired an unfortunate propenſity for gaming, which in London rather increaſed than diminiſhed. In theory he felt as much as any man the folly and guilt of the practice, and wrote an eſſay on the ſubject, expoſing its enormity, but he was ſtill a practical gameſter, and, after the death of his father, loſt much of the property that had devolved to him by the ſolemn event. In the year 1641 he commenced his literary career, and brought out a tragedy, entitled "The Sophy," which, though now forgotten, was well received on the ſtage, and admired in the cloſet. As a political

cal character he adhered to the king's party, and was appointed, ſoon after the breaking out of the civil wars, governor of Farnham caſtle; an honour which he ſoon reſigned, his mind being ill-adapted to a military life. He ſtill remained with the court, and performed ſome ſignal ſervices for the king, during his calamities. It does not appear how the poet was employed, or ſupported, during the interval between the execution of Charles I. and the reſtoration of his ſucceſſor. It was, however, very early in the civil broils of the nation, that he publiſhed his poem, entitled "Cooper's Hill," which very ſoon underwent ſeveral conſiderable editions, and which is ſtill read and referred to, on account of ſome excellent and highly expreſſive lines, and alſo becauſe it is one of the earlieſt examples of local deſcription united with hiſtorical and ſentimental matter. The lines which have excited the moſt attention are part of a deſcription of the river Thames:

O could I flow like thee, and make thy ſtream,
My great example—as it is my theme!
Tho' deep, yet clear; tho' gentle, yet not dull;
Strong without rage: without o'erflowing, full.

Of theſe lines Dr. Johnſon ſays: "But ſo much meaning is confined in ſo few words; the particulars of reſemblance are ſo perſpicaciouſly collected, and every mode of excellence ſeparated from its adjacent fault, by ſo nice a line of limitation; the different parts of the ſentence are ſo accurately adjuſted, and the flow of the laſt couplet is ſo ſmooth and ſweet, that the paſſage, however celebrated, has not been praiſed above its merit. It has beauty peculiar to itſelf, and muſt be numbered among thoſe felicities which cannot be produced at will by wit and labour, but muſt riſe unexpectedly in ſome hour propitious to poetry." Much has been written by way of accounting for the beauty of theſe lines: Mr. Maſon, in his Eſſay on the Power of Numbers and Principles of Harmony, after a critique of ſome length, ſays, "the beauty of this diſtich conſiſts in two things, *viz.* the elegance of the ſtyle, and the harmony of the verſe. The elegance of the ſtyle ariſes from the tranſpoſition of the words, the propriety of the pauſes, and the contraſts of the deſcription: and the harmony of the verſe ariſes from the variety and diſpoſition of the numbers happily adapted to the emphaſis of the words, and the nature of the ſubject."

To return however to the author; ſoon after the reſtoration he obtained the office of ſurveyor of the king's buildings, in the room of Inigo Jones, and was created knight of the bath, and a member of the royal ſociety. Amidſt theſe honours, accompanied with ſome emoluments, he was doomed to much diſquietude from a ſecond marriage, which terminated in a temporary inſanity, from which however he recovered, and continued highly eſteemed by the great and the wiſe till his death, which happened in the ſpring of 1668. His remains were depoſited in Weſtminſter Abbey. Biog. Brit. Johnſon's Poets.

DENIA, in Latin *Dianium*, from Diana, in whoſe honour it was built by a colony from Marſeilles ſome centuries before the Chriſtian era, is a town of Spain, in the province of Valencia, on the declivity of a mountain, ſtretching towards the ſea; 63 miles N. by E. of Alicante, 54 miles S.E. of Valencia, oppoſite the iſland of Ivica, containing 1500 inhabitants. N. lat. 38° 56'. It has a ſtrong caſtle, and a convenient harbour, and is remarkable for a tower of great height, from whence veſſels are perceived at a great diſtance at ſea. The Mooriſh kings reſided here from A. D. 1015 to 1244.

DENIER, in *Coinage*, the French penny; a ſmall copper coin, twelve whereof make a ſol, or French ſhilling.

The French denier is now about the twenty-third part of the Engliſh penny. It is ſubdivided into two mailles, and the maille into two oboles. Anciently denier was a general name for all ſorts of monies in France; as nummus for thoſe of Rome. Thus, a piece of gold money was called denier d'or, ſilver money, denier d'argent: after the ſame manner as the Romans ſaid nummus aureus, and nummus argenteus.

There are two kinds of deniers; the one Tournois, the other Pariſis; whereof the latter was worth a fourth part more than the former, and was called monnoy royale, or forte monnoye, and ſometimes denier d'or, and denier à valeur d'or. See MONEY, &c.

There are at preſent in France ſeveral little copper pieces, which, having no proper name, are diſtinguiſhed only by their value in deniers; ſuch are the pieces of 36. 30. 24. 18. 12. 6. 4. and 2 deniers. The pieces of 4 and 2 deniers were coined at Straſburg for currency in their province of Alſace, purſuant to the declaration of Sept. 6, 1695. Thoſe of ſix deniers were coined in the mints of Aix, Montpelier, Rochelle, Bourdeaux, and Nantz, by the edict of 1709, and are little current. Poſt. Dict. Comm.

DENIS, ST., in *Geography*. See ST. DENYS.

DENIS, *St.*, the chief town of the iſle of Reunion, formerly called Bourbon; and the reſidence of the governor of the colony. The abbé de la Caille has, by aſtronomical obſervations, aſcertained the ſituation of the town in 20° 51' S. lat., and 53° 10' E. long. from the meridian of Paris.

DENIZEN, from the Britiſh *dinaſddyn*, man of the city, or *dineſyddl*, free of the city, in *Law*, an alien enfranchiſed in England by the king's letters-patent, and donation; and thereby enabled, in many reſpects, to do as the king's native ſubjects do: namely, to purchaſe, poſſeſs, and deviſe lands, &c.

Denizenſhip is a right inferior to naturalization by parliament: for a ſtranger naturalized may inherit lands by deſcent which a denizen cannot. A denizen is in a kind of middle ſtate between an alien and a natural born ſubject, and partakes of both of them. He may take lands by purchaſe or deviſe, which an alien may not; but cannot take by inheritance; (11 Rep. 67.) for his parent, through whom he muſt claim, being an alien, had no inheritable blood, and therefore, could convey none to the ſon. And, upon a like defect of hereditary blood, the iſſue of a denizen, born *before* denization, cannot inherit to him; but his iſſue born *after*, may. (Co. Litt. c. 8. 8 Vaugh. 285.) A denizen is not excuſed from paying the alien's duty, (ſtat. 22 Hen VIII.) and ſome other mercantile burthens. No denizen can be of the privy council, or either houſe of parliament, or have any office of truſt civil or military, or be capable of any grant of lands, &c. from the crown. (Stat. 12 Will. III. cap. 2.) See ALIEN.

Add, that, in the charter, whereby a perſon is made a denizen, there is uſually ſome clauſe or other, which abridges him of that full benefit which natural ſubjects enjoy.

When a man is thus enfranchiſed, he is ſaid to be *ad fidem regis Angliæ*, or under the king's protection; till ſuch time his goods might be ſeized to the king's uſe.

DENMARK, in *Geography*, in Latin *Dania*, in German *Dänemark*, one of the moſt ancient monarchies of modern Europe; compriſes 1. Denmark Proper, or the peninſula of Jutland, the ſouthern part of which is called the duchy of Sleſwick; with ſeveral iſlands in the Baltic, the principal of which are Zealand, Funen, Laaland, Langeland and Falſter. 2. The duchy of Holſtein in Germany. 3. The kingdom of Norway with Finmark and part of Lapland. 4. Iceland. 5. The Faro or Ferro iſlands. 6. Greenland. 7. The iſlands

iſlands of St. Thomas, St. Croix, and St. John, in the Weſt Indies, which at this time, 1808, however, are in the poſſeſſion of the Engliſh. And, 8. The eſtabliſhment of Tranquebar, on the coaſt of Coromandel, in the Eaſt Indies, which has ſhared the ſame fate.

Denmark Proper is ſituated between 54° 20′, and 58° 40′ north latitude, and 8° 10′, and 12° 40′ eaſt longitude. It is that part of the Scandinavia of the ancients which they called Cherſoneſus Cimbrica. Its name ſeems to be derived from the ancient Teutonic words *dane* or *thane*, a prince or lord, and *mark*, a boundary or frontier country, correſponding in ſome degree with the German *marggrafſchaft*, a frontier country, confided to the protection of an earl. Saxo Grammaticus, however, is of opinion that Denmark ſignifies the country of Dan, who is ſuppoſed to have lived 1038 years before the Chriſtian era, and to have raiſed himſelf to the throne by his courage and ſkill in war. But it is uncertain whether any ſuch king ever exiſted, unleſs it be Dan Mikillati, or the Haughty, mentioned by the hiſtorians of Iceland as having reigned in the year of Chriſt 146. Others pretend that the river Eyder, which ſeparates Denmark from Germany, was anciently called Don, Dana, or Dena, and that all the country now called Jutland was from that river named Dania, or Denmark, which appellation was alſo applied to the conquered iſlands. The name of Denmark may perhaps be traced in the old Britiſh word *Dan*, a ſtrong fortification.

Nearly at the time when Rome paſſed under the authority of emperors, that part of the north of Europe, known to the Romans by the name of Scandinavia, was invaded by a fierce people emigrated from the banks of Boryſthenes and the Tanaïs. The natives adopted the language, religion, and manners of their conquerors. With them they formed a nation that acted a conſpicuous part in the revolution which altered the political exiſtence of Europe after the fall of the Roman empire. Three diſtinct ſtates aroſe by degrees, Denmark, Sweden, and Norway; yet the uncertainty of their limits created frequent and bloody contentions. At the death of Rolf Krake, who is ſuppoſed to have reigned in the ſixth century, ſeveral tributary chiefs ſhared Denmark among themſelves and formed ſmall independent kingdoms; but new diſſenſions aroſe, and at length the three kingdoms of Denmark, Sweden, and Norway united under one chief, formed a powerful monarchy under the deſcendants of the firſt kings of Denmark. The ancient annals of the north extol the exploits of Ragnar Lodbroek, the laſt of thoſe powerful princes. In his attempt to invade England he was made a priſoner and put to death. His ſons divided his extenſive dominions among themſelves. Denmark again acknowledged a ſeparate king.

Powerful rivals, however, ſtarted up in ſome provinces; it was but in the tenth century that they were ſubdued. Schonen, Halland, and Blekingen, three Swediſh provinces ſituated on the other ſide of the Sound, were ceded by Emund, king of Sweden, to Swein. This king conquered all Norway and a conſiderable part of England; the complete conqueſt of which was achieved by his ſon Knut, or Canute the Great. But Magnus, a deſcendant from the kings of Norway, reconquered that kingdom in 1036, and England ſhook off the Daniſh yoke at the death of Hardeknut, or Hardy Canute, one of the ſons of Canute the Great, after whom the Daniſh crown paſſed in 1076 to his ſiſter's ſon, Swein Eſbrithſon. The latter began a dynaſty which held the ſceptre of Denmark for nearly four hundred years.

In the twelfth century Waldemar I. waged war againſt the Vandals who occupied the greateſt part of northern Germany. He took the iſland of Rugen, the town of Stettin, and ſeveral other places in Pomerania. In 1165 he is ſaid to have laid the foundations of Dantzic. In 1169 he ſubdued Courland, and eaſily maintained his authority in his new poſſeſſions, the emperor Frederick Barbaroſſa being favourable to his ſchemes of aggrandizement. He died in 1180. In the year 1195 his ſon Canute cauſed a muſter to be made of all the men fit to bear arms in his dominions, and ordered each province to fit out its proportion of ſhipping, when the whole naval force of Denmark was found to conſiſt of 670 ſhips. Aſſiſted by his brother, and by Abſalom biſhop of Roſchild, he made the conqueſt of part of Holſtein and of the cities of Hamburgh and Lubeck. Both the duke of Pomerania and the prince of Mecklenburg acknowledged themſelves his vaſſals. He died in 1202, and left the throne to his brother Waldemar II., a no leſs ambitious and warlike prince.

After having obtained from the emperor of Germany the ſanction of his claims on the countries conquered from the empire during the two preceding reigns, Waldemar II. ſet ſail for Eſthonia to convert the idolatrous inhabitants of that coaſt of the Baltic to Chriſtianity. But diſmayed at the unuſual ſight of numerous hordes of ſavages, clothed in ſkins, ready to oppoſe them, his troops were going to fly; when, encouraged by the biſhops who attended the king, they ruſhed on the enemy. The report of a banner having been ſent from heaven rallied the fugitives, and led them on to victory. This banner, which was religiouſly kept as a precious relic, under the name of Danebrog, became the oriflame or ſacred ſtandard of Denmark. The vanquiſhed Eſthonians acknowledged the God of the Chriſtians, and ſubmitted to Waldemar, whoſe powerful ſway was extended to both the ſouthern and eaſtern coaſts of the Baltic.

From an account copied by Pontanus from Wilfeld, who aſſerts that he had it from a regiſter kept by Waldemar's ſteward, it appears that the tributary provinces ſent in daily 24 laſts of oats, 24 laſts of rye, half that quantity of wheat, 13 talents of butter and cheeſe, and nine of honey, 24 oxen, 300 ſheep, 200 hogs, and 600 marks of coined money, beſides fines, forfeitures, taxes on law ſuits and pleadings, and other contingencies, amounting in all to upwards of 100,000 marks a-day. With this almoſt incredible revenue, 1400 great and ſmall ſhips of war were kept in conſtant ſervice for the uſe of the crown. Each ſhip carried 121 ſoldiers.

But Waldemar outlived the greatneſs of his power and the ſplendour of his glory. In the year 1223, Henry earl of Schwerin, a prince of Mecklenburg, ſurpriſed and carried him off whilſt he was engaged in a chace. The conquered countries immediately proclaimed their independence. Waldemar was kept a cloſe priſoner for three years, at the end of which he obtained his liberty on the moſt humiliating conditions, to the obſervation of which he bound himſelf by a ſolemn oath. Having however procured a diſpenſation from the pope, he attempted to regain his loſt dominions, and in the year 1227 entered Holſtein with a numerous army. But fortune no longer befriended him. His troops were defeated with great ſlaughter by the Germans at Bornhoevede. At his death, which happened in 1242, Denmark, of all his conqueſts in the Baltic, retained only a ſmall part of Eſthonia and the iſland of Rugen, which a hundred years later paſſed under the dominion of the dukes of Pomerania. Eſthonia was ſold in the year 1346 to the knights of the Teutonic order, who at that time were ſovereigns of Pruſſia.

But before theſe two laſt remnants of the conqueſts of three fortunate princes were loſt, Denmark experienced a long ſeries of misfortunes. Waldemar II. had left the crown to his eldeſt ſon Eric, and the duchy of Sleſwick to his ſecond ſon Abel. In the year 1250, Eric intreated

Abel's

Abel's mediation with the princes of Holſtein, with whom he was at war; but Abel had him treacherouſly murdered at ſea. Abel however did not long enjoy a crown which he had ſo infamouſly acquired. His ſubjects having riſen in arms againſt him in 1252, he was ſlain in a battle which he fought to quell the inſurrection.

Chriſtopher I., who ſucceeded Abel on the throne, had to reſiſt the uſurpations of ſeveral rivals. His more fortunate ſucceſſor, Eric Menved, kept thoſe potent vaſſals in awe. But under Chriſtopher II. the kingdom was torn by the moſt violent factions. The nobles aſſumed arrogant powers; the towns to reſiſt them, ſent deputies to the herredage or diets of the kingdom; and the peaſants or farmers, who as land owners had till then been ranked among thoſe nobles that were not in the king's ſervice, began to form a ſeparate claſs. Theſe encroachments left the king a bare ſhadow of authority, and ſcarcely any revenue. In this diſtreſs he mortgaged ſeveral provinces to the very vaſſals whoſe power he vainly attempted to reduce. The death of Eric, duke of Sleſwick, which happened in 1325, increaſed his difficulties. The duke having left a ſon under age, Chriſtopher claimed the guardianſhip of the young prince; but his claim was reſiſted by Gerhard, earl of Holſtein, as maternal uncle of the minor. Chriſtopher had recourſe to arms; but was defeated near Gottorp. Encouraged in their factious views by this defeat, his rebellious ſubjects proclaimed that Chriſtopher and his eldeſt ſon Eric had forfeited the crown. Eric fell into the hands of the rebels, who kept him cloſely confined in a ſtrong caſtle. The king himſelf fled into Mecklenburg with his two younger ſons Otto and Waldemar. The young duke of Sleſwick, whoſe name was alſo Waldemar, was at firſt proclaimed king, and his duchy given as an hereditary and independent fief to his uncle Gerhard. The factious barons provided for themſelves each at his own convenience. But this arrangement was almoſt as ſoon annulled as formed. Waldemar kept the duchy of Sleſwick; Gerhard took poſſeſſion of Jutland and the iſland of Funen. The diſcontented nobles ſhared the other iſlands. The king of Sweden recovered Schonen, Halland, and Blekingen. The unfortunate Chriſtopher returned to Denmark ſome time after, and died in a corner of the province of Laaland, the only part of his dominions that recognized his authority. Eric his eldeſt ſon had paid the debt of nature before him. Otto the youngeſt was a priſoner of Gerhard, by whom he had been defeated in battle. The fugitive Waldemar had found an aſylum at the court of the emperor of Germany.

Waldemar of Sleſwick now claimed the crown; but Gerhard his uncle enjoyed the regal power, until he was aſſaſſinated near Randers, in the year 1340. Exaſperated at the aſcendency which the houſe of Holſtein had gained, the nation called Waldemar, the youngeſt ſon of Chriſtopher II., to the throne. Supported by the emperor and the margraves of Brandenburg, he eaſily recovered his hereditary dominions, and reigned by the name of Waldemar III. A treaty of peace was concluded between the new king, the duke of Sleſwick, and the earl of Holſtein. The duke renounced the crown, but kept the duchy as an hereditary fief.

Waldemar III. ſoon redeemed the provinces which had been mortgaged. A ſkilful negociation with Magnus Smek, king of Sweden, ended in the recovery of Schonen, Halland, and Blekingen. During his reign the foundation was laid to that political combination which for more than a century ſubjected a large portion of the north of Europe to the Daniſh power, and effected the ſtill laſting union of Norway with Denmark. Waldemar had a daughter named Margaret, who to the graces of her ſex joined talents and qualities which are generally conſidered as the excluſive appanage of men, and which in the ſequel gained her the ſurname of the Semiramis of the North. Her he married to Hakon Hagen or Haquin VII. king of Norway, ſon to the king of Sweden.

Waldemar III. died in the year 1378, and with him ended the dynaſty of the Eſtrithides in the male line. His grandſon Olaf or Olaus ſucceeded him on the throne of Denmark, and after the death of the king of Norway, aſcended likewiſe the throne of that kingdom. But his reign was not long; he died very young, nine years after his grandfather Waldemar. His mother Margaret, being ſtill a widow, inherited the double crown to which there was no male aſpirant left. Her bold genius ſoon inſpired her with a moſt extenſive project.

Sweden was a prey to domeſtic convulſions. Diſcord raged among the nobles, the clergy, and the people. Albert of Mecklenburg had been called to the Swediſh throne. Deſtitute of the qualifications requiſite to ſuppreſs factious tumults, he fell a victim to national broils. Margaret, whoſe power was firmly eſtabliſhed in Denmark and Norway, obſerved the Swedes with a watchful eye. She kept among them emiſſaries who prepared the minds of the people for her vaſt deſigns. A love intrigue with one of the moſt diſtinguiſhed Swediſh noblemen enabled her to gain partizans among the nobility, and an ardent zeal for the intereſts of the church, combined with a rigid obſervance of religious ceremonies, captivated alike the clergy and the people. Albert ſtill fancied himſelf firmly ſeated on the throne of Sweden when the crown was given to Margaret by the moſt powerful party. To recover his power the dethroned monarch took up arms; but the battle of Fahlkœping, which was fought in the year 1389, confirmed his misfortune.

Secure of her triple diadem, Margaret aſſembled the ſtates of the three kingdoms in the town of Calmar, and propoſed a perpetual union of the three crowns, which was decreed. Her adopted ſon, Eric of Pomerania, was proclaimed her ſucceſſor. The memorable treaty by which the union was effected, was concluded on the 13th of July, 1397, and is known by the appellation of the "Union of Calmar."

But neither Margaret's immediate ſucceſſor Eric, nor Chriſtopher of Bavaria, who was choſen to ſucceed the latter, being poſſeſſed of any ſhare of Margaret's abilities, the union of Calmar was not of long duration. Norway alone continued united with Denmark. The kingdom of Sweden ſoon recovered its independency.

Notwithſtanding the ſolemn renewal of the union in the year 1436, the Swedes choſe Charles Knutſon for their king, and had three adminiſtrators, Sten Sture the elder, Swante Sture, and Sten Sture the younger. The union, however, was not yet formally diſſolved; but at length the impolitic conduct of Chriſtian or Chriſtiern II. was the ſignal of an inſurrection, which broke aſunder the political chain that had been forged for Sweden at Calmar. See SWEDEN.

In the year 1448, after Chriſtopher of Bavaria, the Danes choſe Chriſtiern or Chriſtian, earl of Oldenburg, for their king. He reigned by the name of Chriſtian I., and it is from him that the preſent royal family of Denmark is deſcended. His ſon John was choſen his ſucceſſor in 1481, and forced to ſhare Sleſwick and Holſtein with his brother Frederick. Like all the preceding kings who were elected by the ſtates, John, and his ſon Chriſtian II., who ſucceeded him in 1513, were obliged to ſign at their acceſſion to the throne, a capitulation or charter of privileges, by which they

granted conſiderable immunities to the nobility. The Daniſh monarchs were little more than preſidents of a ſenate compoſed of the principal nobles, who continually encroached at once on the rights of the commons, and on the prerogative of the kings. In vain did Chriſtian II. attempt to reſiſt their overbearing influence. His fiery ſpirit prompted him to meaſures of equal ſeverity againſt a violent ariſtocracy, and an inſolent hierarchy, at a time when he was at open war with the Hanſeatic towns. Factious nobles, and arrogant prieſts, miſrepreſented his beſt intentions, and it is difficult to aſcertain whether or to what degree he deſerved the ſtigma of tyranny which has been affixed to his name. The Swedes were the firſt to renounce him. He was obliged to fly from that kingdom. Guſtavus Ericſon Vaſa was proclaimed king of Sweden in 1523, and in the ſame year the Danes rebelled againſt Chriſtian II., and called his uncle Frederick, duke of Holſtein, to the throne. By flying with his wife and children into the Netherlands, Chriſtian in ſome degree ſanctioned the election. Frederick continued in the ſecure poſſeſſion of the crown, and reigned by the name of Frederick I. until the 10th of April 1533, when he died. The opinions of Luther, which he himſelf embraced, made great progreſs in Denmark during his reign; but the Reformation was not formally introduced before the year 1536, under his ſucceſſor Chriſtian III. whoſe ſon Frederick II. aſſiſted by his able miniſter, Peter Oxe, turned the attention of the Danes towards commerce, regulated the Sound dues, and brought under his dominion that portion of the duchy of Holſtein, known by the name of Ditmars or Ditmarſh.

Frederick II. was ſucceeded at his death by his ſon Chriſtian IV. who, in the year 1615, introduced the firſt ſtanding army in Denmark. By the acquiſition of three-fifths of the county of Pinneberg, in Holſtein, he extended the ſouthern part of the Daniſh dominions to the very gates of Hamburgh; but experienced conſiderable loſſes on his eaſtern and northern frontier.

The brilliant ſucceſs of Guſtavus Adolphus of Sweden, the abilities of the generals who had the command of the armies after this great prince, and the diplomatic talents of Oxenſtierna, had given to Sweden a preponderating influence in Germany. During the protracted and intricate negociations which preceded the peace of Weſtphalia, Chriſtian IV. ſhewed that he was not indifferent to the ambitious views of a power which he conſidered as a formidable rival of Denmark; but unfortunately he raiſed the Sound dues. The meaſure irritated the Dutch, who at that time were the principal traders in the Baltic. They agreed with the Swedes to reſiſt the payment of the new duties. Some Swediſh ſhips were treated with uncommon ſeverity. This induced the Swediſh general Torſtenſon to invade Holſtein in 1643. He penetrated as far as Jutland. Chriſtian IV., little accuſtomed to war, oppoſed but a feeble reſiſtance. The Swediſh fleets, reinforced by a Dutch ſquadron, defeated the Daniſh fleet. Negociations were entered into, and in the year 1645, a peace was concluded at Brömſebro under the mediation of France. Sweden obtained the iſlands of Gothland and Oeſel, the provinces of Jemtland and Herjedalen, which had belonged to Norway, and the ceſſion of Halland for 30 years. Chriſtian IV. died in 1648. The eſtabliſhments of the Danes in the Eaſt Indies, as well as the Daniſh joint companies trading to Greenland and Iceland, date from his reign.

His ſon Frederick III. in the capitulation which he, like all the elective kings, was forced to ſign on his acceſſion to the throne, reluctantly granted ſtill farther immunities to the nobles. They ſoon engroſſed the whole adminiſtration of affairs. The clergy and the commons groaned under their oppreſſive meaſures until theſe inteſtine diviſions induced Charles Guſtavus, king of Sweden, to attack Denmark with a powerful army, and to beſiege Copenhagen itſelf. But Frederick III. encouraged by his queen Sophia Amelia, princeſs of Brunſwick Luneburg, and faithfully aſſiſted by the inhabitants of Copenhagen, held out above two years, when preliminaries of peace were ſigned at Roſchild, in 1651, under the mediation of Cromwell, protector of England. Frederick ceded the provinces of Halland, Blekingen, and Schonen, the iſland of Bornholm, and the biſhoprics of Bohus and Drontheim, in Norway, to the Swedes. But the ambition of the Swediſh monarch, which aimed at nothing leſs than the total conqueſt of Denmark, not being yet ſatisfied, he once more beſieged Copenhagen by ſea and land. On the night of the 11th February, 1659, Charles Guſtavus ordered a general aſſault; but his troops were valiantly repulſed on all points, and a Dutch fleet almoſt at the ſame time defeated the Swediſh fleet. The gallant ſpirit of the Swediſh hero could not brook theſe misfortunes. Charles Guſtavus died in the beginning of the year 1660, and Frederick III. kept the Daniſh crown. A new treaty was concluded at Copenhagen, in 1660, under the mediation of France and England. The iſland of Bornholm, and the biſhopric of Drontheim, in Norway, were reſtored to Denmark; but Schonen, Blekingen, and Halland, were left to Sweden.

The active zeal and intrepid conduct of Frederick during the two ſieges of Copenhagen, had endeared him to his ſubjects in general, and more particularly to the inhabitants of his capital. Soon after the concluſion of the treaty with Sweden, a diet was ſummoned at Copenhagen, to take into conſideration the diſtreſſed ſtate of the kingdom. The deputies aſſembled on the 8th of September, 1660.

This Daniſh diet of 1660, affords the unparalleled example of a free people deliberately reſigning their liberty into the hands of a monarch whom they had hitherto controlled, and voluntarily granting him deſpotic ſway. To humble the nobles, the clergy and the commons concurred in rendering the power of the king abſolute. Frederick himſelf appeared to take no ſhare whatever in a project which intereſted him moſt; but the queen was zealouſly active in augmenting the number of the king's friends. She brought over to the court party, the field-marſhal John Schack, and another nobleman of the name of Annibal Sehefted. But the principal actors in this extraordinary political revolution, were Swane, biſhop of Zealand, Nanſen, burgomaſter of Copenhagen, Gabel, a German, ſecretary to the privy council, and king's private ſecretary, and Lenthe, likewiſe a German by birth.

The means of raiſing the ſums neceſſary for the national exigencies, were the firſt object of the deliberations of the diet. The nobles propoſed a tax on all articles of conſumption, and offered to ſubmit to it themſelves, but with ſo many reſtrictions and exceptions, that the principal weight of the new impoſt muſt have fallen on the commoners. This propoſal was held out as a mark of the utmoſt condeſcenſion, and accompanied with ſarcaſtic reflections on the riſing influence of the commons and clergy, both of which would not admit of any tax that was not to be levied equally upon all ranks, without any reſerve. They demanded that the demeſnes of the crown, which had till then been farmed by the nobles excluſively, ſhould be let to the higheſt bidder without diſtinction. This demand the nobles conſidered as an arrogant infringement on their privileges. Reproachful expreſſions were uſed by one of the ſenators. A general ferment enſued. The aſſembly broke up. The friends of the

court,

court, availing themſelves of this ſtate of irritation, ſuggeſted the extenſion of the prerogative of the crown as moſt conducive to the happineſs of the nation at large. A fortunate incident haſtened the ſucceſs of their ſchemes.

Biſhop Swane, one of his colleagues, the deputies of Copenhagen, and a few of other towns, had been invited to the hall of the nobility to diſcuſs on a point relating to the new taxes. More commoners attending than were expected, the ſenator Otto Kragg, a proud and violent man, diſmiſſed thoſe whom he thought too many. This inſult increaſed the general ferment. The clergy and the commons having new propoſals to offer, it was aſked how they ſhould be communicated to the ſenate. The recent affront they had experienced was yet freſh in their memory. They determined to apply directly to the prince, without any intermediate communication with the ſenators. The deputation was moſt graciouſly received by the king.

On the 8th of October 1660, Nanſen aſſembled the deputies of the commons to examine the clauſes of the projected ſtamp act. They diſcovered that the bill had been materially altered by the ſenate. Loud murmurs were heard. This general diſcontent encouraged Nanſen to move that the crown ſhould be rendered hereditary, in order that the king might be the maſter. The clergy were aſſembled at the ſame time. Swane made the ſame propoſal, and after having conferred with the commons, read the act for rendering the crown hereditary in the perſon of the king and his poſterity, male and female, which was unanimouſly approved. It was then communicated to the ſenate. The nobles met immediately, but having been taken by ſurprize, they ſeparated without coming to a determination on the ſubject.

The next day a deputation of the commons, headed by the burgomaſter of Copenhagen, waited upon the king to remonſtrate againſt the intended ſtamp act. On their return from the palace, they met the ſenator Kragg, who having inquired whence they came, pointed at the Blue Tower, the ſtate priſon of Copenhagen, ſaying, "Do you know that place?" Nanſen immediately replied, "And you, do you know what is ſuſpended yonder?" pointing at the alarm bell in the ſteeple of St. Mary's.

As the nobles had not ſignified their concurrence on the 10th of October, the clergy and the commons repaired in proceſſion to the ſenate, where they found only four ſenators. They returned in the afternoon, but Kragg anſwered, that the ſenate, which beſides was not complete, could not aſſent to the meaſure propoſed by two inferior orders. The deputies then proceeded to the palace, and being admitted into the royal preſence, offered to render the crown hereditary. The king anſwered that he would inform them of his reſolution after he had conferred with the ſenate. Nugatory negociations took place between the prince and the nobles, ſeveral of whom left the city with the intention to paralyſe the proceedings of the diet. To fruſtrate their deſign, the gates were ſhut. Diſpirited at this meaſure, the nobles on the 12th of October ſignified their concurrence ſo far as to render the crown hereditary in the male line of the royal family: but this offer having been rejected, they concurred the following day with the reſolution of the clergy and the commons without any limitation. A committee of the three orders was appointed to ſettle the tranſaction. The choice of the members was left to the king, who appointed four ſenators, four deputies of the nobles who were not ſenators, five of the clergy, ſeven of the commons, and one of the univerſity of Copenhagen. This committee met on Sunday the 14th of October in the forenoon. Swane and Nanſen obſerved a profound ſilence; but Lange, the deputy of the univerſity, ſuggeſted the neceſſity of eſtabliſhing fundamental laws according to the example of other countries where the crown was likewiſe hereditary. Several deputies ſeconded his propoſition. The principles of different conſtitutions were diſcuſſed; but the biſhops interrupted the diſcuſſion by obſerving that it was noon, that the hour for the afternoon's ſervice was approaching, and that it was proper to adjourn the conference for a few hours. The committee ſat again in the evening; but in the mean time it had been intimated to Lange that his preſence was not required. The annulling of the capitulation or charter ſigned by the king at his acceſſion was unanimouſly agreed upon; but to fix on a new tie between the prince and the ſtates was found more difficult. The nobles claimed the continuation of ſome of their ancient privileges, againſt which the clergy and the commons raiſed violent objections. To end their clamorous debates, the biſhop of Zealand propoſed to render the crown hereditary without any ſtipulation, and to leave to the impartiality of the monarch the deciſion of a point on which they, who were moſt concerned in it, could not agree.

On the 16th of October 1660, the three orders framed the decree by which they rendered the government hereditary in the male and female line; ſtipulating only the right of primogeniture, and the indiviſibility of the monarchy. Nothing, however, was mentioned of abſolute ſovereignty. Frederick Gabel, ſon of Chriſtian Gabel, ſecretary to the privy council, who has been named before as one of the principal agents for the court party, ſtates in his memoirs, that his father ſecretly procured the inſertion of *abſolute ſovereignty* in the act by the printer, and thus contributed to render the power of the Daniſh monarchs abſolute: but moſt of the Daniſh writers doubt the truth of his aſſertion. Indeed the term is found in other acts publiſhed before the royal law, which eſtabliſhed the deſpotiſm of the Daniſh kings.

The new oath of allegiance was taken on the 18th of October. The king promiſed to eſtabliſh a form of government by which his ſubjects ſhould be certain of enjoying the advantages of a Chriſtianlike and merciful adminiſtration under his ſucceſſors. The firſt edict which explicitly proclaims the abſolute power of the king was publiſhed in Denmark on the 10th of January 1661, in Norway on the 7th of Auguſt 1661, in Iceland on the 28th of July 1662, and in the Faro Iſlands on the 14th of Auguſt of the ſame year. It was only four years after, that the royal law of Denmark, which is ſtill the baſis of the Daniſh conſtitution, was framed by biſhop Swane and the king's ſecretary Schumacher, afterwards known by the name of count Griffenfeld. This conſtitutional act received the king's ſignature on the 14th of November 1665, but remained in the archives of the crown during the reign of Frederick III., and was only promulgated on the acceſſion of Chriſtian V. to the throne in 1670. Frederick IV. cauſed this law to be engraved in 1709, with an introduction of his own; an abſtract of it will be given under the head of the Daniſh Conſtitution.

From all theſe circumſtances, on which we have purpoſely expatiated with ſome length, it appears evident that the Daniſh people were with much addreſs cajoled into the acceptance of a deſpotic government. The intentions of the commons to diminiſh the power of the nobles by rendering the crown hereditary, did not imply that they meant to renounce their ancient freedom, and to inveſt the monarch with unbounded authority. They were gradually drawn into this conceſſion. When the royal law was promulgated, they could not recal the ſteps they had taken,

and perhaps the joy which they felt at having cruſhed their noble oppreſſors, rendered them inſenſible to the chains which they had eventually forged for themſelves.

Frederick III. was ſucceeded, in 1670, by his ſon Chriſtian V. Not only was the royal law proclaimed at his coronation, but he alſo introduced ſeveral new regulations, which all tended more or leſs to ſtrengthen his abſolute power. He raiſed ſeveral nobles to the dignity of counts and barons, fixed their privileges, and inſtituted the Danebrog order of knighthood. The acquiſition of the counties of Oldenburg and Delmenhorſt, in Weſtphalia, which reverted to Denmark through the death of the earl Anthony Gunther, compenſated in ſome degree for Chriſtian's loſſes in Sweden, with which power he had been forced to ſign a treaty on the terms preſcribed by France, after an obſtinate and unſucceſsful war. He was alſo forced to reſtore the duchy of Holſtein to duke Albert, whom he had treacherouſly detained at Rendſburg, and whoſe poſſeſſions he had invaded. By the treaty concluded at Altona in 1689, under the mediation of the emperor of Germany, the king of Sweden, and the republic of Holland, Albert was alſo confirmed in the poſſeſſion of Sleſwick.

Chriſtian V. died in 1699. His ſucceſſor Frederick IV. jealous of the increaſing rival power of Frederick duke of Holſtein, who had married the ſiſter of Charles XII. of Sweden, laid ſiege to Tonningen, which the duke had fortified with particular care. Charles XII., bent upon avenging his brother-in-law, invaded Denmark, and would have taken Copenhagen, had not the Daniſh king agreed to the peace of Travendahl, which was concluded in 1700, in favour of the duke. But fortune having at length deſerted Charles, after a ſeries of the moſt aſtoniſhing ſucceſſes, his general, Stenbock, was forced to throw himſelf into Tonningen, whilſt Charles was an exile at Bender. This circumſtance occaſioned a new war in Holſtein. Frederick, the brother-in-law to Charles, had been killed at the battle of Cliſſau in 1702. His ſon Charles Frederick, a minor, reigned under the guardianſhip of his uncle Chriſtian Auguſtus, biſhop of Lubeck. When Tonningen opened its gates to Stenbock, the king of Denmark accuſed the houſe of Holſtein Gottorp of being leagued with Sweden, and occupied the duchy with his troops. At the death of Charles XII. the young duke claimed the Swediſh crown, but was forced to yield to Ulrica Eleonora and Frederick of Heſſe Caſſel, her huſband. The king of Denmark concluded a peace with the young duke in 1720, by which he kept poſſeſſion of Sleſwick, and reſtored only part of Holſtein. As Sweden did not oppoſe theſe terms, and as the obſervation of the treaty was guaranteed by England and France, Charles Frederick ſubmitted, but ſolemnly proteſted againſt the injuſtice of the arrangement. He ſoon after married the eldeſt daughter of the czar Peter the Great; and in 1741, their ſon Peter Ulric was nominated by the empreſs Elizabeth, heir to the Ruſſian dominions.

After the death of Frederick IV. his ſon, Chriſtian Frederick, better known by the appellation of Chriſtian VI., mounted the Daniſh throne in the year 1730. To render his ſubjects happy was the firſt wiſh of his heart, and to promote the arts of peace his principal ſtudy. The ruins of the palace of Copenhagen, which was deſtroyed by fire in 1794, evince his taſte in architecture. A diſpute with the king of England, in 1738, about the lordſhip of Steinhorſt, in which ſome blood was ſpilt, terminated in a treaty by which Great Britain paid a ſubſidy of 70,000 *l.* ſterling a-year, on condition that Denmark ſhould keep 7000 troops on foot for the protection of Hanover.

Chriſtian VI. died in 1746, and was ſucceeded by his ſon Frederick V. who, three years before, had married the princeſs Louiſa, daughter to the king of England. Aſſiſted by the elder count Bernſtorf, he improved upon his father's plans for the happineſs of his people: but the new financial and commercial regulations which he introduced were chiefly the work of count Schimmelmann. He took no concern in the ſeven years' war in Germany; yet it was through his mediation that the capitulation of Cloſter Seven was agreed upon between the late duke of Cumberland and the French general Richelieu. Some time after the death of his firſt queen, who was the mother of his ſucceſſor, Chriſtian VII., Frederick V. married a daughter of the duke of Brunſwick Wolfenbuttel. Towards the latter end of his reign, Peter Ulric of Holſtein, who had aſcended the throne of Ruſſia, revived his pretenſions to the whole of Holſtein and the duchy of Sleſwick. His menaces unfortunately induced Frederick to call into his ſervice the count St. Germain, a French officer, whoſe injudicious and haſty reforms in the Daniſh army had almoſt cauſed in Denmark a revolution as fatal as that which his raſhneſs in reforming the French military prepared for France. The Ruſſian general Romanzow was ordered to enter into Holſtein, but he had not yet reached his deſtination when Peter loſt his crown and his life. Catherine recalled the army, and Denmark continued to enjoy the comfort of peace. Another part of Holſtein, that of Ploen, had reverted to Denmark in 1761. As ſoon as the authority of Catherine was firmly eſtabliſhed in Ruſſia, the court of Copenhagen made ſome propoſitions to the court of St. Peterſburg relative to the exchange of the remaining part of Holſtein Gottorp againſt the counties of Oldenburg and Delmenhorſt: but whilſt the count Ernſt Bernſtorff, miniſter of foreign affairs, was zealouſly exerting himſelf in the accompliſhment of this project, Frederick V. died on the 14th of January, 1766.

His ſon Chriſtian VII. ſignalized his acceſſion to the throne by the emancipation of the peaſants on the royal demeſnes, who till then had been held in a ſtate of dependence not far ſhort of ſlavery. A proviſional convention was ſigned with Ruſſia in 1767, reſpecting the exchange of Holſtein; but the tranſaction itſelf was delayed till Paul Petrowitz, as heir of the German poſſeſſions of the unfortunate Peter Ulric, had attained the proper age to ratify the treaty by his ſignature.

Chriſtian VII. married the Engliſh princeſs Caroline Matilda, youngeſt ſiſter to king George III. But his want of firmneſs, and the intrigues of the queen dowager his mother-in-law, involved the young queen in the moſt ſerious misfortune. Ambitious to raiſe her own ſon Frederick to the throne, the queen dowager ſowed the ſeeds of diſſenſion between the king and his conſort. She placed perſons about the monarch to keep him conſtantly engaged in riot and debauchery, and magnified his faults to the unſuſpecting queen, who yet contrived to live on good terms with her royal huſband. All the plans of the old queen failed until the king raiſed his phyſician, Struenſee, a young German doctor, to the dignity of a count, and appointed him his prime miniſter. Inſtigated by an unbounded ambition, this giddy young man, who was not without a ſhare of great political talents, raſhly began to introduce the moſt unexpected reforms, which created him an hoſt of enemies among the old courtiers whom he diſplaced. Deaf to the warning voice of his friend Brandt, who ſhared with him the royal favour, he attempted innovations in ſeveral departments of the ſtate at once. Some of the principal military officers attached to the queen dowager, accuſed him loudly of an intention to overthrow the government by ſuperſeding the king on the ſcore of incapacity, and declaring

claring Carolina Matilda regent of the kingdom during the minority of her ſon.

On the 16th of January 1772, a maſked ball was given at court. The young queen, after having danced the greateſt part of the night with Struenſee, retired about two in the morning. At four, prince Frederick and the queen dowager, accompanied by general Eichſtedt and count Rantzau, went to the king to inform him that the queen, with count Struenſee and Brandt, were at that moment drawing up an act of renunciation to the crown, which they would compel him to ſign, and that he muſt give immediate orders for their being arreſted. The king heſitated, but having been threatened into compliance, count Rantzau proceeded to the apartments of the queen, and conveyed her, together with her infant princeſs, to the caſtle of Cronenburg. Struenſee and Brandt were confined in ſeparate dungeons, ironed, and treated with barbarous ſeverity. They underwent frequent examinations. The fear of the rack extorted from Struenſee the confeſſion of a criminal converſation with the queen. She certainly appears to have taken particular delight in the ſociety of him, who was the favourite of her huſband; yet no intimacy between them was ever proved. Struenſee and Brandt, after having had their right hands cut off, were beheaded on the 28th of April 1772. Their bodies were quartered. A treatment ſo inhuman reflects no ſmall diſgrace on the prince, who had honoured Struenſee in particular with the name of friend. By the interference of the Engliſh miniſter, queen Carolina Matilda was ſuffered to leave Denmark in a Britiſh frigate, which conveyed her to Hanover. She reſided in the palace of Zell, where ſhe died three years afterwards, aged 23 years and 10 months.

After this ſanguinary revolution, count Guldberg was placed at the head of the king's council. He rendered his adminiſtration popular by the promulgation of a law in favour of the natives of Denmark, called the law of "indigenate," and conſidered as one of the fundamental laws of the kingdom. The grand duke Paul Petrowitz having in the mean time attained his majority, the negociations with Ruſſia were reſumed, and a definitive treaty ſigned at Garſkoezelo on the 21ſt of May, and at Fredenſburg on the 1ſt of July 1773. By this treaty the counties of Oldenburg and Delmenhorſt were ceded to the grand duke of Ruſſia, inſtead of which the king of Denmark was put in poſſeſſion of the whole of Holſtein. Paul Petrowitz renounced the two counties in favour of Frederick Auguſtus, biſhop of Lubeck, from whom they devolved to his ſon, Peter Frederick William, who was raiſed to the dignity of a duke of the German empire.

In 1780 Chriſtian VII. acceded to the armed neutrality propoſed by the empreſs of Ruſſia. But the debility of his underſtanding diſqualifying him every day more and more for the management of public affairs, another court revolution took place on the 14th of April, 1784. The queen dowager's friends were removed from the king's councils, and a new council was formed under the auſpices of the crown prince, who had not yet attained his ſeventeenth year. No inſtrument ſigned by the king was declared to be valid, unleſs counterſigned by the crown prince. The commencement of the adminiſtration of this prince was marked by the moſt beneficial meaſures for the proſperity of the country. By the advice of count Bernſtorff, the younger, the Daniſh peaſants were all reſtored to complete freedom, and their emancipation was accompliſhed in a manner ſo gradual and ſo cautious, that it challenges imitation wherever the chains of a long ſlavery are to be broken. The ſlave-trade was alſo gradually aboliſhed by the diſintereſted exertions of count Schimmelmann, who was himſelf poſſeſſed of large eſtates in the Daniſh Weſt-India iſlands. Order was reſtored to the finances of the country, the national debt reduced, uſeful knowledge more generally diffuſed by the moſt liberal patronage beſtowed on ſocieties for the promotion of learning, arts and ſciences, the adminiſtration of juſtice improved, induſtry encouraged, commerce freed of its former ſhackles, and in the midſt of the wars occaſioned by the French revolution the ſtricteſt neutrality was maintained. Every ſolicitation to declare againſt France proved vain, but the menaces of Ruſſia ſucceeded at length in determining Denmark to accede to the confederacy which the northern powers formed againſt Great Britain in 1801. This league however was quickly diſſolved by the appearance of an Engliſh fleet under admirals Parker and Nelſon, in the Baltic, and Nelſon's forcing the line of defence formed by the Daniſh fleet before Copenhagen, on the memorable 2d of April 1801, when the Danes fought with a bravery equal to that of their gallant oppoſers. The diſpute between Great Britain and the northern powers being ſoon after amicably ſettled, Denmark recovered the iſlands in the Weſt Indies, and the ſettlement of Tranquebar, on the coaſt of Coromandel, which had been forced to yield to the Britiſh arms.

The battle of the 2d of April 1801, had interrupted the calm of an eighty years' peace, and appeared to be the commencement of a new era in the naval and military eſtabliſhments of Denmark, which received ſo great an acceſſion of ſtrength, that full confidence was repoſed in the future exertions of either the army or navy on any emergency. Yet the war between England and France having been renewed in 1803, and France having ſucceſſively triumphed over Auſtria and Pruſſia, and formed an intimate connection with Ruſſia, it was ſuppoſed that Denmark would no longer be able to reſiſt the united ſolicitations of Ruſſia and France, and be forced to declare againſt England; particularly as a conſiderable French and Spaniſh force was hovering on its frontier. Under this ſuppoſition, the Engliſh miniſtry propoſed to the crown prince to ſurrender the Daniſh navy into the hands of the king of Great Britain, until the reſtoration of a general peace. This propoſal was indignantly rejected, the prince aſſerted his ability, and proteſted his readineſs to maintain his neutrality, and to defend his country againſt the firſt power that dared to attack it. The peace of Tilſit, which France had juſt concluded with Ruſſia and Pruſſia, left to that ambitious and daring power ſuch irreſiſtible means to compel the feeble kingdom of Denmark to turn its weapons againſt England, that the latter country conſidered herſelf juſtified in reſorting to extraordinary meaſures. In the month of Auguſt, 1807, a ſtrong Engliſh fleet ſurrounded the iſland of Zealand, and landed an army of 20,000 men. Copenhagen was bombarded. (See COPENHAGEN.) On the ſeventh of September the Engliſh took poſſeſſion of the citadel for ſix weeks, and all the Daniſh ſhips then at Copenhagen, being 18 ſail of the line, 15 frigates, ſix ſloops, and 25 gun-boats, together with all the ſtores of the naval arſenal of Chriſtianſholm, were ſurrendered to the diſpoſal of the king of Great Britain. Exaſperated at this treatment, the crown prince declared war againſt England, and ſoon after againſt Sweden, its only ally. He invoked the aid of France. The French marſhal Bernadotte (prince of Ponte Corvo) arrived at Copenhagen on the 16th of March, 1808, at the very moment when intelligence was received in that capital of the death of Chriſtian VII., who died at Rendſburg on the 13th of March, 1808. The crown prince was proclaimed king on the 16th of March by the name of Frederick VI.

On the 22d of March, the prince Chriſtian, Daniſh man of war, ſtruck to the Engliſh, after an obſtinate engagement,

in

in which the Danes had 50 killed and 88 wounded. As the ſhip had been run aſhore, ſhe was ſet on fire and burnt. Thus the Daniſh navy was reduced to one ſingle ſhip of the line.

In the mean time 15000 Spaniſh, 10,000 French, and 5000 Dutch troops, entered the Daniſh continental dominions to aſſiſt the Danes, and 387 veſſels were taken up for the invaſion of Sweden. Several privateers haraſſed the Engliſh traders in the Baltic, and committed ſucceſsful depredations. Frequent engagements took place between Daniſh gun-boats and Engliſh brigs. The Swedes, under baron Armfeldt, entered Norway, and drove the Danes acroſs the Glommen, but could not penetrate to Chriſtiania. A ſtrong Engliſh armament, under the command of ſir James Saumarez, prevented the intended attack upon Sweden. Bernadotte complained in May of the remiſſneſs of the Daniſh government in completing the warlike preparations neceſſary for the execution of the plans with which he was charged. The iſland of Heiligeland, at the mouth of the Elbe, which is conſidered as part of Sleſwick, and the Daniſh poſſeſſions in the Eaſt and Weſt Indies, were occupied by Engliſh troops.

For the remainder of the hiſtory of Denmark, from the month of July 1808, ſee NORWAY.

The boundaries of Denmark Proper are, the river Eyder to the ſouth, which divides it from Holſtein, and conſequently from Germany; to the weſt the North ſea, or German ocean, which the Danes call the Weſtern ocean; to the north that part of the north ſea which is called the Cattegat, and Shaggerack, by which it is divided from Norway; and to the eaſt that inlet into the Baltic ſea, known by the name of the Sound, or Ore-Sound, which divides Denmark from Sweden.

The extent of Denmark Proper is about 4964 Engliſh ſquare miles. It is divided into two parts, the peninſula of Jutland, anciently called Cherſoneſus Cimbrica, and the iſlands at the entrance of the Baltic.

Jutland was anciently divided into North and South Jutland; but the former is now ſimply called Jutland, and the latter Sleſwick, which ſee.

The iſlands at the entrance of the Baltic are two large ones, Zealand and Funen, and five ſmall ones, Laaland, Langeland, Falſter, Moen, Bornholm, which ſee.

Denmark Proper counts 68 towns, 22 market towns, 7000 villages, 948 lordſhips, and 15 earldoms or counties. The principal towns are Copenhagen, Flenſburg, Elſineur, Sleſwick, and Odenſee.

The climate of Denmark Proper is variable and moiſt, but rather temperate on account of the vapours of the ſurrounding ſea. In the northern parts the winter is ſometimes very ſevere; the entrance of the Baltic through the Sound is often obſtructed with ice, and has been at times ſo completely frozen over as to be croſſed by heavy loaden carriages.

The ſoil in general is rather ſandy, but fertile in grain and paſturage. The weſtern coaſt of Sleſwick is expoſed to the inroads of the North ſea, on which account it is kept embanked at a very great expence, and theſe embankments are often extended. The land which the ſea leaves behind is uncommonly fertile, and is called *koog*. The appearance of the country in general is low and flat. There are but a few hills of a bleak and wild aſpect, and ſome high cliffs on the coaſt; yet the country is agreeably variegated with woods and lakes. Denmark has alſo many little ſtreams which interſect the country in various directions. Two of them, the Guden, and the Eyder, deſerve the name of rivers. In the northern part, a large creek of the ſea called the Lymfiord, extends from the Cattegat through more than ſeventy Engliſh miles. It is navigable, and contains numerous ſmall iſlands. The Baltic and the North ſea communicate by three great inlets acroſs Denmark Proper, and on its northern frontier, *viz.* the Sound, the Great Belt, and the Little Belt. The diſtance from Elſineur to Helſinborg in Sweden, acroſs the Sound, is 1331 fathoms, or about 2½ Engliſh miles; between Copenhagen and Malmoë in Sweden, the diſtance is nearly 20 Engliſh miles. The paſſage over the Great Belt from Nyeborg in Funen to Corſoer in Zealand is about 20 Engliſh miles, and from Aſſens to Aaroeſundsfærge over the Little Belt, about 10; but there is another paſſage between Middlefarth and Snoghey, which is not quite two Engliſh miles.

Denmark has an extenſive ſea-coaſt; which, beſides yielding a little amber, abounds in oyſters, muſcles, and herrings, and affords uncommon conveniencies for trade. The roads are not very good; the turnpike roads extend only about 90 miles from Copenhagen.

The population of Denmark, including Norway, Iceland, Greenland, and the Faro iſlands, amounts to two millions and a half, *viz.*

Denmark Proper counts	930,000 inhabitants.
Sleſwick and Holſtein	620,000
Norway, Iceland, &c.	950,000

From 1769 to 1785, the whole population had been increaſed by 200,000 ſouls. The annual average ſurplus of the born over the dead is from 12 to 20,000.

In 1794, the numbers were;

Of the born in Denmark Proper	27,539	Dead	25,956
Sleſwick and Holſtein	17,642		14,306
Norway, Iceland, &c.	28,069		17,344
Born	73,250	Dead	57,606
	57,606		
Surplus	15,644		

In 1806 the numbers were;

Of the born in Denmark Proper	29,949	Dead	22,588
Sleſwick and Holſtein	18,533		14,635
Norway, Iceland, &c.	26,777		18,482
Born	75,259	Dead	55,705
	55,705		
Surplus	19,554		

The language of Denmark is that dialect of the Teutonic, which is called the Scandinavian. It differs very little from the Swediſh language; its chief difference ſeems to ariſe from the drawling tone with which it is pronounced by the Danes. The pronunciation of the Norwegians comes nearer that of the Swedes. There is beſides a greater admixture of German words in the Daniſh language, than in the Swediſh, the German language being univerſally ſpoken beyond Flenſburg, in Sleſwick, till very near the Little Belt, and generally underſtood in the capital. It is but lately that the Danes have taken any pride in their own language. All the laws and public inſcriptions are now in Daniſh.

Some fuller's earth, alum, and vitriol found in Jutland, and ſome porcelain clay obtained in the iſland of Bornholm, ſeem to conſtitute the whole of the mineral productions of Denmark Proper. The fiſheries thrive beſt on the weſtern coaſt of Jutland, and in the creek called Lymfiord. Herrings and flounders are exported on a ſmall ſcale from Aalburg and Skagen. The oyſter banks, which extend from Rypen to Heiligeland, are let to farmers on account of the crown.

With regard to agriculture, Denmark and Holſtein produce rye, barley, oats, and wheat in ſuch abundance, as to ſupply Norway, and frequently to export corn to other countries to the annual amount of 100,000*l.* ſterling. In 1803, an attempt was made in the vicinity of Copenhagen towards cultivating madder. The plant ſucceeded uncommonly well, though it ſtood a ſevere winter. The crop proved of a ſuperior quality. Hops are cultivated chiefly in Funen, tobacco near Fredericia in Jutland, and in Zealand, and Falſter: Rape-ſeed chiefly in Sleſwick and Holſtein. The agriculture of Funen and the ſouth of Jutland is compared by Mr. Marſhal to that of England.

Since the emancipation of the peaſants, agriculture, in all its branches, has been rapidly improving in Denmark. But the Daniſh farmers are chiefly known as excellent graziers. Denmark ſupplies Germany, France, Ruſſia, and Sweden with horſes for both heavy and light cavalry, beſides coach-horſes. Thoſe of Zealand, Funen, Jutland, Sleſwick, and Holſtein are moſt eſteemed. The annual amount of the horſes ſold is reckoned 200,000*l.* ſterling. Black cattle are exported in great numbers to Holland. Many thouſands of oxen, after they have been fattened in the marſh lands, are ſent to the German markets. Salt-beef, butter, and cheeſe, form conſiderable articles of trade. Live hogs and great quantities of bacon are exported to Norway, Holland, and ſeveral ports of the Baltic. In 1780 they counted in Denmark 847,000 ſheep. The beſt wool is that near Eyderſtadt; it is long and fine.

Horticulture is very much encouraged in Denmark. Government furniſhes the farmers gratis with fruit trees from the royal nurſeries.

In the beginning of the eighteenth century, Denmark was almoſt without manufactures. It was only at the end of the northern war that Frederick IV. could ſeriouſly think of encouraging their introduction into his dominions. His ſucceſſor Chriſtian VI. zealouſly exerted himſelf in promoting their ſucceſs. The importation of cloth, ſilks, and other articles, was ſtrictly prohibited. Government has continued ever ſince to ſpur the induſtry of the Danes. From the year 1736 to 1774 not leſs than 800,000 dollars have been ſpent on the encouragement of manufactures. Ancient prohibitory regulations have often been renewed; the queſtion has even been agitated whether the importation of foreign manufactures could be reſtricted by a national coſtume; and ſo late as 1783, an attempt was made to wean the Danes from foreign luxuries by means of ſumptuary laws. But the Daniſh manufactures are not yet ſufficient for the home market.

Linen cloth is wove in ſeveral places, yet Denmark is obliged to purchaſe a third of the coarſe and almoſt all the fine linen it wants from abroad. However ſpinning ſchools, and premiums awarded to the beſt ſpinners and weavers, ſtrengthen the hope of the Daniſh government that the linen manufactures will rapidly improve. Neither is ſail cloth manufactured in ſufficient quantity. Of the woollen manufactures, that of the Goldhouſe at Copenhagen, which is a monopoly of the crown, is the moſt important. With worſted ſtockings Denmark is abundantly provided from Iceland and the Faro iſlands. This manufacture flouriſhes likewiſe in Jutland, where many a ſingle village produces annually from 16 to 20,000 pair. The ſilk manufacturers of Copenhagen and Altona make all ſorts of ſilks, chiefly ribbands and ſtockings. But the calico-printing and cotton manufactures of Copenhagen, Huſum and Wandſbeck, are far more extenſive. Hence the importation of cottons and prints is totally prohibited. The thread lace maufacture of Tondern, which was begun in 1646, and employed moſtly Dutch thread, though not ſo flouriſhing as formerly, gives ſtill employment to 10,000 hands. Paper mills are not yet ſufficient for the home-conſumption. Denmark imports annually 100,000 dollars worth of foreign paper. New mills are however every day eſtabliſhed, and the exportation of rags has been ſtopped.

Denmark is abundantly ſupplied with tanners and leather curriers, chiefly and beſt at Altona. Daniſh leather gloves, which are principally made at Odenſee, are famous all over Europe. The goodneſs of the leather at this place is ſuppoſed to ariſe from a certain property in the river water, in which it is ſoaked, for tanning. The manufactures of earthen ware flouriſh moſt at Aarhuus and Rypen, which ſend their pottery into ſeveral parts of Germany. The royal china manufacture of Copenhagen makes excellent ware, but it ſtill wants the aſſiſtance of government. The amount of the goods manufactured from 1785 till 1792, was 277,349 dollars; but no more than 185,539 dollars could be diſpoſed of. There are ſeveral ſugar refiners, copper, braſs, and iron works, and cannon founderies. The moſt important among the latter is that which was eſtabliſhed in 1756 by general Clauſen, at Frederickſwerk near the Iſefiord, a bay of the ſea on the northern ſhore of Zealand. The works conſiſt of a foundery for cannon and balls, and for making ſaltpetre and gunpowder. Count Schimmelmann's manufactory, near Elſineur, furniſhes the army with muſkets, bayonets, and ſabres. It fabricates annually 3500 muſkets.

Anciently the whole trade of Denmark was carried on excluſively by the Hanſeatic towns. Their firſt competitors were the Dutch, and afterwards in ſome degree the Engliſh. Chriſtian V. encouraged his ſubjects to trade beyond the ſeas, but it was only after peace had been reſtored in the north under Frederick IV. that the Daniſh commerce began to flouriſh. It rapidly extended under Chriſtian VI., and was at its greateſt height in 1792, if an opinion may be formed from the number of merchant veſſels. In 1747 they amounted to 1748, twenty years later to 2053, in 1792 to 3331, and in 1799 only to 2173. But it ought to be remembered that the tonnage of ſhips has been of late years every where increaſed.

The trade of Denmark, with its dependencies and colonies, is conſiderable. That with Iceland, which had long been clogged by reſtrictions, excluſive companies, and monopolies of the crown, has been tripled within the laſt five and twenty years, ſince it has been a free trade. It employs now from 60 to 70 veſſels, and is carried on in Daniſh bottoms only. The trade to the Faro iſlands, which within the laſt fifteen years has been opened to all Daniſh ſubjects, employs but a few veſſels. That to Finmark has alſo been allowed free to all Daniſh ſubjects ſince 1789, and bids fair to become of great importance. The Greenlanders exchange their fiſh, oil, whalebones, and downs with the manufactures of Europe, and ſome colonial produce: but the whale fiſhery conſtitutes the principal part of the Greenland trade. The trade to Norway is moſtly a paſſive one in Daniſh and foreign veſſels. The Daniſh north and Iceland companies are both extinct.

The trade to the Eaſt Indies is in the hands of a privileged company, but not excluſively. Private individuals may fit out veſſels for the Eaſt Indies and China, on their own account on paying to the company five *per cent.* for what they export, and eight *per cent.* on the return cargoes. In 1797, there were 11 return cargoes for private account, three of which came from the Daniſh eſtabliſhments, and eight from other ports in the Eaſt Indies. In 1798 and 1799, the return cargoes for private account were thirteen in

in number, four from Daniſh and nine from other eſtabliſhments in the Eaſt Indies. The increaſed vigilance of the Britiſh government againſt the ſmuggling of tea into England, and the commutation act, have cauſed a remarkable declenſion in the proſperity of the Daniſh Eaſt India company. Only one ſhip has returned annually from Canton ſince 1789, and in 1792 and 1794 there has been no return cargo whatever for the company's account. The dividend in 1797 was 12 *per cent.*

Since the year 1754, the trade to the Weſt Indies is free to all Daniſh ſubjects; yet Copenhagen receives almoſt excluſively the return cargoes from St. Croix, which iſland in 1792 ſent 60,949 cwt. of ſugar, 7000 puncheons of rum, and 1500 cwt. of cotton. The two other Daniſh Weſt India iſlands, St. Thomas and St. John, furniſhed about half as much. They ſend beſides coffee, tobacco, and other colonial productions, which they purchaſe from the neighbouring Antilles. The whole Daniſh Weſt India trade employs in time of peace 30 ſhips and 500 ſailors annually.

The trade to the Mediterranean has been very much improved ſince the year 1755. In 1798, 126 Daniſh veſſels ſailed for Meſſina, Barcelona, Algeſiras, Marſeilles, Toulon, Naples, Leghorn, Genoa, Venice, Ancona, and Trieſte; and Denmark counted 55 return cargoes from the Mediterranean. Moſt of the Daniſh veſſels are employed in the carrying trade, the Daniſh flag being reſpected by the dey of Algiers and the Sublime Porte.

Denmark has alſo a briſk trade with Germany, the countries round the Baltic, Sweden, and Pruſſia. But the balance ſeems to be againſt Denmark, ſince it imports much linen and woollen cloth, wood, brandy, and haberdaſhery from Germany; corn, flax, hemp, wool, and other articles from Pruſſia. This trade employs above 300 veſſels. The whole Daniſh export and import trade is however chiefly carried on in Daniſh bottoms; and its extenſive carrying trade, together with the great balance of production in Norway, leaves no doubt that the balance of trade upon the whole is in favour of the Daniſh dominions. In 1803, there were entered inwards into the ſeveral ports of Great Britain, from the ports of Denmark and Norway, 1536 ſhips, two-fifths of which were Britiſh.

Copenhagen is the emporium of the Daniſh trade, and has increaſed with it in ſize and wealth. In 1798 there were entered inwards at Copenhagen

2066 veſſels from foreign ports,
2490 from Daniſh ports,
414 from Norway,
912 from Sleſwick and Holſtein,
92 from the Eaſt and Weſt Indies.

In all 5974

The other commercial places in Denmark Proper are Elſineur, Aalborg, and Colding; in Norway, Bergen, Drontheim, and Drammen; in Sleſwick, Flenſburg; in Holſtein, Altona and Gluckſtadt.

Accounts in Denmark are kept by rixdollars, marks, and ſhillings, 16 of which make a mark, and ſix marks a dollar. Two mark Daniſh and two ſhilling Daniſh are equal to one mark and one ſhilling Lubiſh. Since 1788, ſpecies has been coined for Sleſwick and Holſtein, which is alſo current in Denmark Proper, and is 25 *per cent.* better than the old currency. Its double value is ſtamped on each piece, as one ſpecies dollar 60 ſhilling currency. This coin comes down to all ſizes, as low as the 24th part of a ſpecies dollar, or 2½ ſhilling currency. The actual coins current are in gold, Chriſtian-d'ors at five dollars, and ducats at 12 marks Daniſh, or ſix marks Lubiſh; in ſilver, crowns at four marks Daniſh. There are alſo 24 ſhilling pieces, four of which make a rix-dollar, 16, 12, 8, 4, 2, and 1 ſhilling pieces; in copper, fyrke or dreilinge, two of which make a ſhilling. Beſides theſe coins, there is an extenſive paper currency, conſiſting of the notes of the Copenhagen and Altona banks.

Sciences and arts flouriſh to a great degree in Denmark, which has to boaſt of the celebrated aſtronomer Tycho Brahe. It has two univerſities, one at Copenhagen, where moſt of the learned ſocieties are eſtabliſhed, (ſee COPENHAGEN,) and the other at Kiel, which ſee. Kongſberg has, ſince 1786, a ſeminary for miners, in which mathematics and mineralogy are publicly taught. There are reading clubs in Zealand and Jutland, where the peaſants read the newſpapers and public journals. The preſs is under no ſtricter regulations than in England: *viz.* that no printer dares print anonymous publications without making himſelf liable to anſwer for their contents, or to give up their author. The Daniſh government has acknowledged the principle, that the more a ſtate is verging towards deſpotiſm, the more it ought to allow the liberty of the preſs. It is by that means only, that the ſubjects of a deſpot are raiſed to the rank of citizens. But the Daniſh government has often abandoned this principle; and where is the ſafety in a deſpotic country, that this will not frequently be the caſe?

The predominant religion of Denmark is the Lutheran, and the religious inſtitutions connected with the ſtate relate excluſively to this church. The hierarchy conſiſts of twelve biſhops or ſuperintendents; ſix in Denmark, *viz.* Zealand, Funen, Ripen, Aarhuus, Wiborg, and Aalborg; four in Norway, *viz.* Chriſtiania, Chriſtianſand, Bergen, and Drontheim; two in Iceland, *viz.* Skaalholt and Hoolum. There is no archbiſhop; but the biſhops of Zealand and Chriſtiania are metropolitans. The inferior clergy are archdeacons or provoſts, pariſh prieſts, and chaplains. Holſtein has no biſhop, but only a general ſuperintendent. The livings ſeldom exceed 400*l.*; but never fall ſhort of 60*l. per annum*, excepting in Iceland, where ſome livings are hardly worth 5*l.*, and the beſt do not exceed 20*l.* a-year. The king, as ſupreme head of the church, nominates the biſhops; but the archdeacons are choſen by the pariſh prieſts, and the latter by the patrons of the livings.

At Copenhagen, Altona, and Frederickſtadt, other creeds are tolerated. The Mennonites, in the juriſdiction of Haderſleben, enjoy great privileges; they are exempted from the military conſcription. The Jews are moſt liberally treated in the Daniſh dominions. They are 1500 in number at Copenhagen, and 2500 at Altona.

The Danes in general are religious without ſuperſtition, and the lower orders, though bigotted, are leſs ſo than the Norwegians. Their morals are upon the whole tolerably pure. The predominant vices of the lower claſſes are lazineſs, gluttony, and an exceſſive fondneſs for ſpirituous liquors; that of the higher orders the love of ſhow and pleaſure. The manners of the nobility and gentry are refined and eaſy, partaking rather of the old French ſchool. All ranks are equally attentive to ſtrangers. Hoſpitality and affability pervade all claſſes. The favourite diverſions of the Danes are the theatre, cards, muſic, dancing, and in winter driving on ſledges over the ſnow. The middle ranks, to enjoy their favourite amuſement of dancing and playing at cards, meet in clubs, the number of which at Copenhagen is greater than in any other town on the continent of equal or ſuperior population. Thither they take the ſtranger to whom they wiſh to ſhew any civility; and thus avoid the expence of an entertainment at their own houſes. There are no baths nor watering places in Denmark.

The

DENMARK.

The conſtitution of Denmark, as eſtabliſhed by the Royal Law, Kong's Low, Lex Regia of the 14th of November 1665, is an abſolute monarchy: the king is bound by no human law; and either in eccleſiaſtical or civil affairs, acknowledges no ſuperior or judge but God. He has the power of making and repealing laws. He is the ſource of all titles, dignities, honours, and offices. He has the power of making war and peace, of forming alliances, and impoſing taxes. He is the ſupreme chief of the church, and alone enjoys every right of ſovereignty by whatever name it may be called.

But the king of Denmark muſt be of the Lutheran church, deſcended from Frederick III. born in wedlock. He is of age at his entering his fourteenth year. At the death of a king the throne devolves inſtantly to the next heir without any other formality; but the new king muſt be ſolemnly anointed and crowned, and this ceremony may take place even during his minority.

The inſignia of the coronation are kept in the royal palace of Roſenburg.

The Daniſh nobility have no ſhare whatever in the government. There are no dukes but of the royal family. Beſides the duke of Holſtein Auguſtenburg, there is no other Daniſh prince on appanage. Neither are there any marquiſſes. The nobles are ſimply counts, barons, and noblemen.

Frederick VI. the preſent king of Denmark, was born on the 28th of January 1768 of Chriſtian VII. king of Denmark, and Carolina Matilda, princeſs of England. He ſucceeded his father on the 13th of March 1808.

The royal title is: Frederick VI. by the grace of God, king of Denmark and Norway, of the Goths and Vandals, duke of Sleſwick, Holſtein, Stormarn, Ditmarſh, &c. The title of the eldeſt ſon is crown prince. The younger ſons are called hereditary princes. The royal arms are parted by the Danebrog croſs into four principal quarters. In the firſt or, three lions paſſant gardant azure, ſurrounded with nine hearts gules for Denmark. In the ſecond gules, a lion rampant crowned or, holding a Daniſh battle-axe argent for Norway. In the third azure three crowns or for Denmark, Norway, and Sweden. In the fourth or a lion leopardiſed azure, with nine hearts gules for ancient Gothland. The inefcutcheon quarterly in the firſt or two lions paſſant azure for Sleſwick. In the ſecond gules three nettle leaves argent, pierced with three nails of the croſs charged with a ſmall eſcutcheon argent for Holſtein: in the third gules a cygnet argent gorged with a crown or for Stormarn: in the fourth gules, a cavalier armed argent, holding a ſword pommelled or for Ditmarſh. Upon all, an inefcutcheon in the centre party per pale, or two bars gules for Delmenhorſt; and azure a croſs party or for Oldenburg. The ſupporters are two ſavages armed with clubs.

There are but two orders of knighthood in Denmark. The firſt is the order of the Elephant, of which Canute VI. is falſely conſidered as the founder. In 1464 Chriſtian I. eſtabliſhed a monaſtic ſociety with the badge of an elephant, which probably ſuggeſted to Frederick II. the idea of founding the order of the Elephant. He gave it away for the firſt time on the third of May 1580. It was afterwards provided with new regulations by Chriſtian V. on the firſt of December 1693. The badge of this order is a white enamelled elephant ſurmounted with a caſtle, ſet in diamonds. The chain conſiſts of two elephants and two caſtles alternately. It is worn, ſuſpended by a ſky-blue watered ribbon, over the left ſhoulder. The motto is: "Magnanimi pretium." On the left breaſt the knights wear an octagon ſilver ſtar. The number of the knights, beſides the ſovereign, is limited to thirty. It confers the title of excellency, and can be beſtowed only upon perſons profeſſing the proteſtant religion. The ſecond order of knighthood in Denmark is the Danebrog order. It derives its name from the once celebrated royal banner called the Danebrog, which was loſt in the war with the inhabitants of Ditmarſh, a province of Holſtein. It is reported to have been founded by Waldemar II. in 1219: but it is more probable that Chriſtian V. was its real founder on the 12th of October 1671. The ſtatutes of the order were only ſigned on the 1ſt of September 1693. The badge of the Danebrog order is a white ribbon edged red, worn ſcarf-wiſe over the right ſhoulder, having at its end a ſmall white enamelled croſs with diamonds. In the centre of this croſs are the letters W. for Waldemar, and C. V. for Chriſtian V. with the royal crown, and underneath the word RESTITUTOR. The motto of the order is: "Teſſera Fidelium." The knights wear an octagon ſilver ſtar on the right breaſt. Any perſon not of royal blood, who is to be made a knight of the Elephant, muſt firſt be a knight of the Danebrog, and have worn its badge at leaſt for a few days. The number of knights was originally limited to 50; but in 1787 there were not leſs than 193 knights of the Danebrog.

The Daniſh court was formerly very ſplendid and expenſive: it is now one of the moſt economical in Europe, though the number of perſons attached to the court be ſtill very great. In 1783 there were 296 chamberlains, and 91 gentlemen of the bed chamber, 218 of whom had been appointed by Chriſtian VII. The national theatre of Copenhagen is partly a royal eſtabliſhment.

The adminiſtration of the kingdom is in the hands of a privy council, in which the king preſides. The number of its members is not limited. Subordinated to the privy council are the following five departments: 1. The Daniſh chancery, which ſuperintends the courts of juſtice, eccleſiaſtical affairs, public education, patents, privileges, &c. for Denmark and Norway. 2. The German chancery, which tranſacts the ſame buſineſs for Sleſwick and Holſtein. 3. The department of foreign affairs. 4. The financial college or board of revenue; and, 5. The treaſury. There is a miniſter at the head of each of theſe departments.

The fundamental laws of Denmark are the royal law of 1665, which fixes the conſtitution, and the law of the 15th of January 1776, called the Indigenate's Law, which excludes foreigners from public offices, unleſs they be naturalized. In civil and criminal matters, Denmark acknowledges no laws but the Danſke Low, or code of Chriſtian III. publiſhed in 1683. It has been often reviſed, and a great many ſtatutes have been added. An abridgement has been publiſhed in Engliſh under the title of "The Daniſh Laws faithfully tranſlated for the Uſe of the Engliſh Inhabitants of the Daniſh Settlements in America;" London, 1756, 8vo. in which the tranſlator has omitted the ſecond book, and the ſections relating to the peaſants. This Daniſh code is conciſe, clear, and plain, and remarkable for its mildneſs and equity. Even lord Moleſworth, who judges ſo unfavourably of every thing Daniſh, is reluctantly obliged to praiſe the Daniſh code of laws. The courts of juſtice are divided into three claſſes, *viz.* the inferior courts, the ſuperior courts, and the ſupreme tribunal of Copenhagen. Inferior courts are in the country: 1. The herretſdinge, compoſed of one judge, herretsfoget, and eight aſſeſſors, choſen among the reſpectable houſekeepers of the diſtrict (herred), called ſtokemen, beſides a clerk called ding or herredſkriver. A herred, or diſtrict, generally conſiſts of 40 or 50 pariſhes. Theſe courts are held once a week. 2. The birkdinge, or courts of juſtice on the eſtates of the noblemen, which are not

not ſubmitted to the juriſdiction of the herretſdinge. 3. The city juriſdictions, or byetinge, aſſiſted by a certain number of aſſeſſors choſen among the moſt reſpectable houſekeepers of the place, and called dingmen. At Copenhagen, however, all the inhabitants without diſtinction are, ſince 1771, under a ſeparate court, called the "Court and Town Juriſdiction," (Hof und Stadt Gericht) from which the appeal goes directly to the ſupreme tribunal. But from all other inferior courts of juſtice, the appeal firſt goes to the ſuperior courts, called landdinge, which are compoſed of country judges, called landdommers, and are held once a month. The clerks are called landdingſherer. There are five landdinge in Denmark, one for Zealand, at Ringſtædt; one for Funen and Langeland, at Odenſee; one for Jutland, at Wyborg; one for Laland and Falſter at Marieboe; and the fifth at Bornholm.

The ſupreme tribunal of Copenhagen is the higheſt court of juſtice for all the Daniſh dominions. It ſits almoſt the whole year, and is always opened with great ceremonies by the king himſelf in the beginning of March, on the ancient Herredag or Danehoev.

Although the adminiſtration of juſtice in the inferior courts is expeditious, and not very expenſive, yet in order to check the ſpirit of litigation, too prevalent among the Danes, conciliatory committees have been annexed to the inferior courts of juſtice ſince the year 1795. See COPENHAGEN.

The police in Denmark is vigilant and good. A Board of Health (Mediciniſche Collegium) watches over the health of the people, and has appointed a committee for promoting vaccination. (See COPENHAGEN.) But the moſt intereſting inſtitution is the Lying-in Hoſpital, where all midwives in the Daniſh dominions muſt have ſtudied before they are allowed to exerciſe their profeſſion. It is properly a kind of foundling hoſpital, in which mothers may not only place their children, but where they may alſo be delivered. All pregnant women, of whatever condition, religion, or country they may be, are admitted without being aſked any queſtions; they are even allowed to come in maſks, and to continue maſked all the time they are there. The beſt accommodations coſt fifteen dollars *per* week. There are other apartments for twelve and eight dollars, that is about a guinea and a half. This intereſting aſylum is ſaid to have produced a viſible diminution in the number of infanticides, which the mild laws of Denmark rarely puniſh with death. A Board of Alms (Pflege Anſtalts Collegium) ſuperintends the maintenance of the poor, who are ſupported entirely by private charity. No beggars are ſeen on the road or in the ſtreets. The number of charitable foundations in Denmark is very conſiderable, and if the country offers few traces of opulence, it affords, however, no veſtiges of poverty. The meaneſt cottages are clean and comfortable. Denmark, though a proteſtant country, has preſerved ſeveral richly endowed ladies' convents, which afford an excellent education to the daughters of poor noblemen, and in which they find a comfortable aſylum until they are married. The priſons are kept in the ſtate recommended by the immortal Howard. See COPENHAGEN.

The revenues of the crown in Denmark ariſe chiefly,

1. From the demeſnes and the quit-rents paid for thoſe that have been ſold.
2. From the Sound dues. See ELSINEUR.
3. From cuſtom-houſe dues on exports and imports.
4. From the mines, mint, poſt, and ſtamp office.
5. From the land-tax, which varies in the different provinces, and is paid either for the ſuppoſed produce of the ground, or for the number of ploughs, as in Sleſwick and Holſtein, where each plough pays 5*l.* 12*s.* ſterling annually. The duty paid by the ſaw-mills in Norway, is conſidered as a branch of this tax. Every ſaw-mill pays 6*l.* ſterling annually.
6. From the exciſe dues on wine, ſpirits, beer, malt, cattle, leather, and ſeveral articles of food. It alſo includes the marriage-tax, confined to Copenhagen, where the higher ranks pay 10*l.* ſterling on marrying. The tax comes gradually down as low as four ſhillings.
7. From the tax on rank and honours. All the ſubjects of the king of Denmark are claſſed in nine different claſſes. The firſt pays annually 16*l.* ſterling; the ſecond 14*l.*; the third 8*l.*; the fourth 6*l.*; the fifth 3*l.* 4*s.*; the ſixth 3*l.*; the ſeventh 2*l.* 8*s.*; the eighth 1*l.* 12*s.*; the ninth 1*l.* 4*s.*

Penſions of 80*l.* annually, or above, pay ten *per cent.*; from 70 to 80 excluſive, eight; from 60 to 70, ſeven; from 50 to 60, five; from 40 to 50, four; from 30 to 40, three; from 20 to 30, two. Widows pay half of the rank and penſion-tax.

8. From the poll-tax in Denmark Proper.
9. From the profits which the royal lotteries, eſtabliſhed at Copenhagen and Altona, leave to the crown. They are expoſed to great variations. During fourteen years, *viz.* from 1773 to 1787, the gain of the crown amounted to 820 423*l.* ſterling; but from 1787 to 1791, the public regained 403,672 ſterling, leaving a balance of 416,751*l.* ſterling, for the ſpace of eighteen years. The average produce of this gambling impoſt cannot, therefore, be valued at more than 20,000*l.* ſterling, annually.
10. From the impoſts levied in the Daniſh Weſt India iſlands, which uſed to leave an annual clear revenue of about 30,000*l.* ſterling.

On particular emergencies, extraordinary contributions are levied. Thus, on the 5th of January 1807, an additional tax of 1*l.* 4*s.* was laid on every plough, for defraying the expences attending the marching and quartering of the troops in Sleſwick and Holſtein.

The exact amount of the whole annual revenue of Denmark is not known. It may, however, be eſtimated at eight millions of dollars, or 1,600,000*l.* ſterling. In 1784, Mr. Coxe rated it at 1,400,000*l.*, but he acknowledges, in a note to the fifth edition, that it has ſince been increaſed. From 1785 to 1787, Mr. Toze ſuppoſes it to have been 7,270,172 dollars or 1,440,000*l.* Profeſſor Norman of Roſtock, eſtimated it in 1803, at 7,800,000 dollars, or 1,560,000*l.* ſterling. The expenditure, which in former times frequently exceeded the receipts, had not only been made to balance of late years; but there was even a conſiderable ſum appropriated as a ſinking fund for the payment of the national debt, which had been reduced to little more than two millions and a half ſterling. The perilous ſituation in which Denmark has been recently placed, has cauſed an iſſue of exchequer bills, which it will be neceſſary to fund, and which will no doubt raiſe the national debt again to what it was in the year 1790, namely, four millions ſterling.

The military force of Denmark is partly mercenary, and partly a national militia. The former is on a regular eſtabliſhment, and continues in actual ſervice all the year round. It is made up of foreign recruits, who coſt the crown very large ſums, but whoſe number is not very great, and of national recruits, who enliſt for a bounty.

The Daniſh army is properly compoſed of two diſtinct corps, the Daniſh and Norwegian troops, differing very much in their conſtitution.

In Denmark each pariſh (lage) furniſhes one foot ſoldier or cantoniſt, who receives common pay during the four weeks of exerciſe, an annual extra gratification of 1*l.* ſterling,

ling, and four-pence for each Daniſh mile he has to travel to and from his regiment. Men above 36 years of age are free from the conſcription. The horſes for the cavalry are furniſhed by the land-owners, and country clergy for the cantoniſts, and kept by them for an annual gratification from the treaſury. They may uſe theſe horſes for their own perſonal ſervice, but they muſt always keep them in good condition.

In Norway a lage, or diſtrict, furniſhing a man, conſiſts of two complete farms, and the whole army is compoſed of cantoniſts, without any regular troops. The time of ſervice is fixed at nine years, at the end of which they are obliged, in caſe of need, to ſerve ſix years in garriſon towns on the frontiers. The horſes are found and kept by the land-owners, who may employ them to their own uſe. The annual exerciſes laſt only twelve days. The cantoniſts are exerciſed by companies, and every fourth year only by battalions.

The Daniſh regular troops receive new cloathing every third year, the national cantoniſts only every twelfth year. The pay of a common ſoldier is 3*d.* a day, that of a horſeman 3½*d.* with bread. Invalids are provided for in ſeven garriſon companies, and in the hoſpital at Eckernforde. There is a ſchool for one hundred cadets for the land ſervice eſtabliſhed at Copenhagen. Fifty are educated at the expence of government, and fifty on paying for their board. There are two other ſchools of the ſame kind, one at Chriſtiania in Norway, and the other at Rendſburg in Holſtein. In 1799, public lectures were inſtituted at Copenhagen for the inſtruction of non-commiſſioned officers.

The whole Daniſh army conſiſts of 74,791 men, and coſts annually 393,000*l.* ſterling.

On the 19th of January 1801, a new national militia was organized by the name of *Landvaern*. It was to conſiſt of thoſe men, who, having attained their 36th year, are diſmiſſed from the army, and they were to ſerve merely on emergencies, without being incorporated in the army. This ſervice was to be limited to the age of 45. Two regiments of nearly 6000 men each were actually organized in the ſpring of 1801, when the Engliſh threatened the coaſt; and this auxiliary force has been lately called out and differently regulated. In the towns it extends to every male inhabitant capable of bearing arms.

The Daniſh fortreſſes are, Copenhagen, Cronenburg, Corſöer, Nyeborg, Fredericia, and Fladſtrand in Denmark, Rendſburg and Gluckſtadt in Holſtein, Frederickſhald, Aggerhuus near Chriſtiania, Frederickſwærn in Norway, and Vardochus in Finmark. The principal arſenals are at Copenhagen, Rendſburg, Aggerhuus, and Frederickſtadt. The war office is compoſed of a preſident and five aſſeſſors, and has under it three different departments for the cavalry, infantry, and the the fortreſſes.

According to the official Daniſh gazette of the 15th October, 1803, the Daniſh navy conſiſted at that time of 19 ſhips of the line, 15 frigates, 8 brigs, and 13 gun-boats. On the 1ſt of January 1807, the number of officers in the Daniſh fleet was 2 admirals, 2 vice admirals, 3 rear admirals, 10 commodores, 15 commanding captains, 25 captains, 30 captain-lieutenants, 55 firſt lieutenants, and 66 ſecond lieutenants. But as the Daniſh navy has been entirely annihilated, we ſhall defer the account of every thing relating to this ſubject to the article NORWAY (which ſee), under which we ſhall alſo endeavour to ſtate the external relations of Denmark, which are at this moment diſturbed by the war.

With regard to the national character of the Danes, they have always been juſtly conſidered as a brave, generous, and grateful people, hoſpitable and enlightened, attached to their country, but rather ſlow, addicted to pleaſure, intemperate in their food, litigious, and of an iraſcible and revengeful diſpoſition. Coxe's Travels, vol. v. Fr. Thaarup's Statiſtik der Daeniſchen Monarchie, 1796. J. P. Catteau. Tableau des Etats Danois, 1802. C. G. Kuttner's Travels through Denmark in 1798 and 1799. Nord Litéraire, and Archives du Nord.

DENN, a town of Arabia, in the country of Yemen; 40 miles E. of Zebid. N. lat. 14° 15′. E. long. 43° 43′.

DENNEHOUT, a town of Flanders; 5 miles S. of Aloſt.

DENNIS, JOHN, in *Biography*, was the ſon of a ſadler, and born in London in the year 1657. He received his grammar learning at Harrow ſchool, and from thence he was admitted at Caius college, Cambridge. Here he remained ſeveral years, took his degree of M A., and then made the tour of France and Italy. Upon his return, he made himſelf known as a poet and dramatic writer; but neither in theſe departments, nor in political controverſy, in which he engaged, did he make any diſtinguiſhed figure. The public gave him little credit for real talents, and he was often diſguſted and irritated that his labours were ſo ill received. As a critic he is beſt known; his violence in that character procured for him the appellation of "Dennis the Critic;" and his want of temper involved him in perpetual diſputes with the principal writers of the day. Addiſon and Pope did not eſcape his laſh; the latter retorted upon him with equal ſeverity. Toward the cloſe of life Dennis was much diſtreſſed in his circumſtances. As a politician, he had ever eſpouſed the whig party, and when his fortune, which had never been conſiderable, was reduced, he obtained, through the intereſt of the duke of Marlborough, a place in the cuſtom-houſe, which his wants or his extravagance obliged him in a few years to ſell, reſerving, however, an annuity for a certain term. This he outlived, and when he moſt needed the comforts of life he found himſelf completely deſtitute of every thing. To poverty was added the affliction of blindneſs. A play was acted at the Hay-market for his benefit, for which his old opponent, Pope, wrote a prologue, which would have been highly creditable to his candour, had he not taken the advantage of ſneering at the man whom he profeſſed to benefit. Dennis, at that period, was too old or too imbecile to be affected by this inſtance of diſingenuity, which he ſurvived but three weeks; he died on the 5th of Jan. 1734, in the 77th year of his age. In the Biographia Britannica we have a long account of the writings of Mr. Dennis, longer, perhaps, than would be thought neceſſary, by readers in general. Of this, the excellent writer, Dr. Kippis, ſeems aware, and apologizes, by ſaying, that the "article will not be found totally deſtitute of utility. It will add ſomething to the great body of the literary hiſtory of England, and it may ſerve to diſplay the unhappy effects that reſult from the extravagance of ſelf-opinion; an extravagance which is uſually more incident to ſecondary authors, than to thoſe who occupy the higheſt ranks of genius and learning." Biog. Brit.

DENNIS, in *Geography*, a poſt town of America, in the ſtate of Maſſachuſetts, and county of Barnſtaple, incorporated into a townſhip in 1793; it is 80 miles S.E. from Boſton, and 8 from Barnſtaple, and contains 1408 inhabitants. This town comprehends the villages of Nobſcuſſet, of 52 houſes, and Suet of 36 houſes.

DENNIS *Creek*, an American creek, in Cape May county, N. Jerſey; 219 miles from Waſhington.

DENOMINATION, from *denomino*, of *de* and *nomen*, a name, a name impoſed on any thing uſually expreſſing ſome quality predominant therein.

Hence, as the qualities and forms of things are of two kinds, *viz.* internal and external, denomination becomes twofold.

DENOMINATION, *internal*, is that founded on the intrinſic form; thus Peter is denominated learned on account of his learning, which is ſomething internal.

DENOMINATION, *external*, is that founded on, or ariſing from, the external form. Thus, a wall is ſaid to be ſeen and known, from the viſion and cognition employed upon it; and thus Peter is denominated honoured, by reaſon of honour, which is not in the perſon honoured, but in him that honours.

DENOMINATOR, in *Arithmetic*, a term only uſed in ſpeaking of fractions, or broken numbers. See FRACTION.

The denominator of a fraction is the number or letter below the line; ſhewing into how many parts the integer is ſuppoſed to be divided by the fraction.

Thus, in the fraction $\frac{7}{12}$ ſeven twelfths, the number 12 is the denominator, and ſhews that the integer is here divided in 12 parts. So in the fraction $\frac{a}{b}$, b is the denominator.

The denominator always repreſents an integer.

The number above the line, 7, is called the numerator.

DENOMINATOR *of a ratio* is the quotient ariſing from the diviſion of the antecedent by the conſequent.

Thus, 6 is the denominator of the ratio 30 : 5, becauſe 5)30(6. The denominator is what we otherwiſe call the exponent of the ratio.

DE NON RESIDENTIA CLERICI REGIS, in *Law*, the name of an ancient writ, the form whereof ſee 2 Inſt. fol. 624. for excuſing a parſon employed in the king's ſervice for non-reſidence.

DENS CANIS, in *Botany*, *Dog's Tooth violet*. See ERYTHRONIUM.

DENSCHENDORF, in *Geography*, a town of Denmark, in the iſland of Funen; 4 miles W. of Berg.

DENSHIRING, in *Agriculture*, a term formerly applied to the operation of paring off the ſurface of graſs lands, and burning the materials thus produced by ſmothering fire. See PARING and BURNING.

DENS LEONIS, DANDELION. See LEONTODON.

DENSITY, (from the Latin *denſitas*) cloſeneſs, or compactneſs. *Denſity* and *rarity* are oppoſite or relative terms, both referring to the quantity of matter contained in a given ſpace. Take two veſſels, A, and B, of equal capacities. Fill A looſely with cotton, and ſuppoſe it to contain one pound weight of cotton; let two pounds of cotton be forced into the veſſel B; then the cotton in A is ſaid to be rare with reſpect to the cotton in B, and the cotton in B is ſaid to be denſe with reſpect to the cotton in A. Alſo the denſity of the cotton in B is ſaid to be double the denſity of the cotton in A, becauſe it contains a double quantity of it in the like ſpace; and if three pounds of cotton were forced into the veſſel B, then the denſity of it would be treble that of the cotton in A, &c. So that the denſity is proportionate to the quantity of matter contained in a given ſpace. It is evident, that if the capacity of the veſſel B be double that of the veſſel A, then, in order to produce in B a denſity of cotton double that of the cotton in A, four pounds of cotton muſt be forced into B; for if in this caſe the capacity of B be ſuppoſed to be divided into two parts, each part would be equal to A, and each part would contain two pounds of cotton. This explanation, which we have for the ſake of perſpicuity applied to the filling of veſſels with cotton, muſt be applied to all other bodies of any other kind. Hence we learn the following evident and general deductions, or theorems, concerning the relative proportions of the denſities, the bulks, and the weights of bodies.

I. The denſity is directly proportional to, or is as the quotient of the weight divided by the bulk.

II. The weight is as the product of the denſity multiplied by the bulk.

III. The bulk is as the quotient of the weight divided by the denſity.

If the denſity be called D, the bulk B, and the weight W; then theſe three theorems are, according to the algebraical notation, expreſſed in the following manner; (α being the ſign of conſtant proportion.)

$$\text{I. } D \alpha \frac{W}{B}.$$
$$\text{II. } W \alpha BD.$$
$$\text{III. } B \alpha \frac{W}{D}.$$

Therefore, when two bodies, as M and N, are to be compared together with reſpect to their denſities, weights, and bulks; call the denſity, weight, and bulk of M, reſpectively D, W, B; alſo call the denſity, weight, and bulk of N, reſpectively, d, w, b; then the compariſon for the above three caſes ſtands thus:

$$\text{I. } D : d :: \frac{W}{B} : \frac{w}{b}.$$
$$\text{II. } W : w :: BD : bd.$$
$$\text{III. } B : b :: \frac{W}{D} : \frac{w}{d}.$$

One numerical application of the firſt caſe, will ſufficiently illuſtrate the practical uſe of theſe theorems. Let the weight of the body M be 10 ounces, and its bulk five cubic inches; alſo let the weight of the body N be nine ounces, and its bulk three cubic inches, then the denſity of the body M is to the denſity of the body N, as $\frac{10}{5}$ is to $\frac{9}{3}$; or as two to three. In the preceding paragraphs we have taken it for granted, that the quantity of matter is proportionate to its weight; and, indeed, with bodies of the ſame kind of matter this can hardly be doubted; for inſtance, a lump of gold which weighs ſix pounds, muſt contain twice as much matter as is contained in another lump of gold which weighs three pounds. But with matter of different kind, it is impoſſible to ſay with certainty, that the weights are proportional to the quantities of matter. The weight of a body is meaſured by the force with which the ſubſtance of that body is attracted by the earth; therefore, if the attraction between the earth and a body A, be greater than the attraction between the earth and another body B, then thoſe bodies may contain equal quantities of matter, and have unequal weights. But, in truth, we have no determinate knowledge of the real and intimate eſſence of matter. We diſtinguiſh matter, or bodies, by their properties; and it is impoſſible to ſay, whether matter conſiſts of ſomething eſſential and endowed with ſuch properties, or it is only an aſſemblage of thoſe properties. The moſt general idea is that, *cæteris paribus*, the quantity of matter is proportionate to its ſenſible weight; and in this we muſt for the preſent acquieſce.

The limits of denſity are likewiſe unknown to us. Air is one of the moſt elaſtic of the ponderable fluids known: and experiments ſhew, that a given quantity of air may be compreſſed into a ſpace ſmaller and ſmaller, (and of courſe it may be rendered more and more denſe) in proportion to the power which is applied to compreſs it; ſo that with a double

double force it may be contracted into half the ſpace; with a treble force, it may be contracted into a third part of the original ſpace, and ſo on: and human art has not been able to aſcertain how far this condenſation may be carried on. It has alſo been obſerved, that by removing the preſſure a quantity of air will be enabled to expand itſelf; nor has any limit been diſcovered to this expanſion. Other bodies are compreſſed, and become more denſe in conſequence of the application of an adequate force; but they do not follow the ſame regularity as air; nor do they recover their entire original bulk when the preſſure is removed. All metallic bodies, by preſſing, laminating, or hammering, may be permanently reduced into a ſmaller ſpace, or rendered more denſe; but it is not in our power to ſay how far their denſity may be increaſed.

The ſuſceptibility of condenſation ſhews, that the primitive particles of bodies cannot be in perfect contact with each other; but that they muſt contain a great many pores or vacuities. Indeed, ſir Iſaac Newton was of opinion, that even gold which is the denſeſt body next to platina, is likely to contain more pores or vacuities than real ſolid matter. It is, however, to be obſerved, that this opinion is more verbal, than real; for when in common language we talk of pure gold, or pure ſilver, or pure water, &c. we mean that the gold or the ſilver is unmixed with other metals, or that the water contains no ſolid extraneous matter; but we forget, that the element of heat, or caloric, and the electric fluid are mixed with it. The firſt of theſe fluids is manifeſted by its being expelled in the act of hammering, or preſſing; as under that operation the metallic ſubſtance is unavoidably heated. The exiſtence of the electric fluid in conſiderable quantity is rendered more than probable by the phenomena of galvaniſm. See GALVANISM. Upon this conſideration, therefore, a piece of pure gold, as we call it, is in reality a mixture of gold, caloric, and electricity. Hence, if the real particles of gold are not quite in contact with each other, they are kept apart by the other components of the mixed body, *viz.* by the caloric, and by the electric fluid. It ſeems, then, likely, that if we conſider the gold, the caloric, and the electric fluid as the component parts of the mixed body, which in common language we call pure gold, all theſe parts may be abſolutely in contact with each other. The conſequence of this concluſion would be, that the lump of this pure gold could not be compreſſed into a ſmaller ſpace, unleſs ſome of the ingredients are ſqueezed out of it; and this, in fact, takes place; for the caloric is expelled in the form of ſenſible heat whenever gold is compreſſed. The ſame reaſoning may be applied to all other kinds of compreſſible bodies; and it will be found, that thoſe which are more compreſſible, give out more heat. Thus the compreſſion of air produces heat ſufficient to ſet fire to light combuſtible bodies.

The denſities of bodies are alſo increaſed by cooling, or by the abſtraction of heat. This law, however, is not general; or rather, it does not obtain throughout the whole extent of the ſcale of heat. Water, for inſtance, becomes denſer and denſer by cooling, as far as about the 40th degree of Fahrenheit's thermometer; but below that degree the bulk of water is expanded by farther cooling; which is evidently owing to a cryſtallization, *viz.* to the particles of water diſpoſing themſelves in a peculiar order. The ſame thing, under certain limitations, has been obſerved in various other bodies.

The inveſtigation of the natural and acquired denſities of bodies has, at all times, and eſpecially of late, been particularly attended to by the moſt able philoſophers, as being a ſubject intimately connected with, and ſubſervient to, various inportant branches of natural philoſophy, and to the arts. The denſities of ſolids and fluids are, in fact, their ſpecific gravities, the knowledge of which every body knows to be extenſively uſeful. See SPECIFIC GRAVITY.

The mutual preſſure of fluids upon each other, alſo, of ſolids upon fluids, and *vice verſa*, which are of the utmoſt importance in hydraulics, in naval architecture, &c. is entirely dependent upon their peculiar denſities. See HYDRAULICS and NAVAL ARCHITECTURE. In chemical operations, the denſities of fluids, and eſpecially of ſaline ſolutions, are carefully attended to: for the cryſtallization, and the ſeparation of ſalts, entirely depend upon the proper degree of denſity to which the brine is brought. See CHEMISTRY, SALTS, and CRYSTALLIZATION.

The inveſtigation of the various denſities of the atmoſphere at different times, and at different heights above the ſurface of the earth, enables us, beſides other uſes, to meaſure altitudes by the barometer.

With reſpect to the various denſity of the atmoſphere it will be neceſſary to give a general idea in this place, the more intricate part of it being treated of under the articles ATMOSPHERE, ATMOSPHERICAL LOGARITHMIC, and BAROMETER.

Air actually taken in bottles, at different heights above the ſurface of the earth, (as far as human beings could aſcend,) and afterwards examined with all due precautions, has been found to be leſs denſe according as it was taken at a greater height. Alſo the numerous experiments that have been performed on the compreſſibility and elaſticity of the atmoſpherical air, prove, that by the application of preſſure, the air may be condenſed into a ſpace inverſely proportional to the force which is applied to it; that by removing the preſſure, the air expands in proportion to the quantity of preſſure which is removed; and by remaining a certain time under preſſure, the air loſes no part of its elaſticity. And to theſe properties we know no limits. Therefore, from all theſe facts we may ſafely conclude, that the air of the atmoſphere is denſeſt neareſt to the ſurface of the earth, where it is preſſed by the weight of the whole altitude of the atmoſphere; that it is leſs denſe according as the place is more diſtant from the ſurface, becauſe the ſuperincumbent air is leſs high; and laſtly, that it is impoſſible for us to ſay how far the atmoſphere is extended, becauſe we are not acquainted with the utmoſt limits of the air's expanſibility.

Beſides the compreſſion ariſing from the weight of the ſuperincumbent air, which undoubtedly is the principal cauſe of the various denſity of the atmoſphere; other cauſes concur in the production of that effect. In ſhort all the concurring cauſes are, as far as we know: 1. The various quantity of ſuperincumbent air at different altitudes; 2. The decreaſing attraction of the earth, or the decreaſing weights of bodies, in proportion to the ſquares of the diſtances from the centre of the earth; 3. The action of heat and cold; 4. The admixture of vapours and other fluids; and, 5. The attraction of the ſun and the moon.

From the abovementioned facts, the denſities, and of courſe, the preſſures of the atmoſphere, for different altitudes above the ſurface of the earth, are calculated on the ſuppoſition of the air's denſity, being affected only by the maſs or weight of the ſuperincumbent air; then, thoſe denſities are corrected according as the actual ſtate of the principal of the other concurring cauſes may ſeem to require. Laſtly, the barometer, by which we meaſure theſe denſities or preſſures at different altitudes, will of courſe, indicate the correſponding altitude. See BAROMETER, and the other articles above referred to.

DENSITY *of the Sun and Planets.* To determine the

denſity

denſity of the ſun and planets, is a problem in phyſical aſtronomy, not more intereſting from the information we derive from its reſult, than from the nature of the method by which the ſolution is obtained.

To the antient mathematicians, who certainly were not deficient in their powers of reaſoning, nothing could have appeared more completely out of the reach of human intellect, than to determine by the abſtract properties of number or quantity, any thing relating to the internal ſtructure of bodies, ſo remote and inacceſſible.—Conſiderations of ſome intricacy occur when we wiſh to ſolve this problem, with the greateſt exactneſs our data admit of;—but before we proceed to theſe computations, we would wiſh to give ſuch an explanation of the general nature of the method by which they are effected, as may be intelligible and ſatisfactory to thoſe who may not be familiar with the application of the Newtonian philoſophy, to queſtions of this nature.

The hypotheſis, which it is neceſſary to admit before we can attempt the ſolution of this problem, is that of univerſal gravitation. This ſuppoſes that all bodies (at leaſt thoſe in queſtion) attract each other, in proportion directly to their maſſes or quantities of matter, and inverſely as the ſquares of their diſtances. 1. This hypotheſis is in fact nothing but the enunciation, in the form of theorem, of a very univerſally obſerved phenomenon, and is by no means invalidated by the objections that have been made to it, that it endows matter with metaphyſical and occult qualities. When we ſay that it is the nature of iron to be attracted by the magnet, we mean nothing more, than that every piece of iron on which the experiment has been made, has, without exception, obeyed the magnetic impulſe. The Newtonian hypotheſis, on which all phyſical aſtronomy is built, aſſerts nothing more of gravitation. In every caſe, as far as our obſervation reaches, the reſult anſwers to the ſuppoſition. As it is not abſolutely impoſſible, but that iron may exiſt which is not magnetic, ſo in the regions of the univerſe, worlds may exiſt not ſubject to the laws of attraction. Nor is that ſpecies of attraction which we here conſider any otherwiſe occult or metaphyſical, than as an agent, with whoſe nature and mode of action we are at preſent entirely unacquainted. Its action is doubtleſs communicated through ſome intermediate medium, and two bodies, in what we call free ſpace, probably approach each other, becauſe it would require a greater effort in them to remain at reſt, or to move in any other direction. When we ſee a feather forcibly drawn to a piece of excited ſealing wax, we attribute the phenomenon to the effect of the electric fluid, a name we have given, by analogy, to this extraordinary agent, whoſe nature we know as little of, as of the nature of gravity, and which moſt probably neither reſembles a fluid, nor any other form of matter with which we are acquainted. But to return more immediately to the ſubject—

We are now to ſhew by what train of reaſoning we arrive at the knowledge of the comparative quantity of matter which the ſun and planets contain, relatively to that in the earth.

If a heavy body, for inſtance a cannon ball, be ſuffered to deſcend from a ſtate of reſt, by no other impulſe than its own weight, it will fall towards the earth with a continually increaſing velocity, and will deſcribe about 16 feet in the firſt ſecond of time. This initial velocity of 16 feet in a ſecond, may be taken as a ſtandard meaſure of the attractive power of the earth.

It is demonſtrated by mathematicians, and we will here take it for granted, that the attractive force of a large ſpherical maſs of matter will be the ſame, let the dimenſions of the globe, into which that matter is compreſſed, be what they may. So that if the whole maſs of the earth could be compreſſed into a central point, its attractive force would remain the ſame, and would at 4000 miles diſtance, that is at the ſame diſtance as before, (4000 miles being equal to the earth's radius) cauſe a heavy body to move towards it with an initial velocity of 16 feet in the firſt ſecond of time.

If we ſuppoſe the ball, inſtead of deſcending from a ſtate of reſt, to be projected horizontally from a cannon, it will ſtill equally obey the attractive power of the earth, and will deſcend exactly 16 feet from its horizontal direction in the firſt ſecond of time. If the earth were really compreſſed into a ſmall central ſpace, as we juſt now ſuppoſed, the ball would circulate round it, and would deſcribe a curve, the nature of which would depend on the velocity of projection; but it would always have this property, that at the point of its origin, it would deviate from its tangent 16 feet in the firſt ſecond of time. If the ball be taken up 60 times as far from the centre of the earth, (namely to the diſtance of the moon) the attractive power of the earth will then be diminiſhed 3600 times, (3600 being the ſquare of 60) becauſe the force decreaſes, as the ſquare of the diſtance increaſes; and the ball will deſcend from a ſtate of reſt with an initial velocity of only the $\frac{1}{3600}$th part of 16 feet; and if it be projected as before, ſo as to deſcribe an orbit round the earth, that orbit would deflect from its tangent $\frac{16}{3600}$ feet. And in fact the moon itſelf is found to deflect this quantity from its tangent, which curious coincidence was the firſt confirmation Newton obtained of the truth of his hypotheſis.

If then we could find in our planetary ſyſtem, a ſatellite or ſecondary body, revolving round its principal in an orbit equally diſtant from its centre, as the moon from the centre of the earth, we ſhould eaſily perceive whether that planet contained more or leſs matter than the earth, by obſerving how much the orbit of the ſatellite deflected from the tangent in one ſecond of time. If the deflection was equal to that of the moon we ſhould conclude, the maſs of the planet to be equal to that of the earth; if we found it greater or leſs, it would indicate the maſs of the planet to be greater or leſs in the ſame proportion.

The planet Jupiter affords an obvious example to illuſtrate this reaſoning; its firſt ſatellite revolves round it at a diſtance nearly equal to that of the moon from the earth, but in one ſecond it deflects from its tangent 256 times as much as the moon does. The maſs of Jupiter is therefore 256 times greater than that of the earth. The principles of the calculation are not materially different for ſatellites at different diſtances, it is only neceſſary to compute what the attractive power would be at equal diſtances. The maſs of a planet being thus found, and its magnitude determined by obſervation, its relative denſity may be computed according to the principles deſcribed in the former part of this article.

We ſhall now proceed to explain the practical methods that are uſually employed for the ſolution of this problem—

It has been before ſtated, that if of theſe three things, namely, the magnitude, the maſs, and the denſity of a body, any two be given, the other may be found. The magnitudes of the ſun and planets are here ſuppoſed to be determined by obſervation; to aſcertain their denſities, we begin by computing their maſſes.

The maſs of a planet may be computed by comparing the velocity in its orbit round the ſun, either with the velocity of its ſatellite, or with the force of gravity at its ſurface. If the planet has no ſatellite, aſtronomers have recourſe to a method much leſs accurate, depending on the effect which

by

by obſervation the planet is found to produce in diſturbing the motions of the other planets. For the determination of the denſity of Mercury, La Place prefers deducing it from analogy, by obſerving the law of the denſities of the reſt of the planets relatively to their diſtances from the ſun; but it muſt be acknowledged, that ſuch determination is little better than mere conjecture.

The firſt of the above methods is founded upon a theorem, derived from the doctrine of central forces.

Let F repreſent the attractive force of the ſun,
T the periodic time of the planet, whoſe maſs we wiſh to determine,
r the radius of the obit of the planet,
r' the radius of the orbit of the ſatellite.
F′, the attractive force of the planet upon its ſatellite.
T′, the periodic time of the ſatellite.
M, the maſs of the ſun.
M′, the maſs of the planet.

It will then appear that $M : M' :: \frac{r^3}{T^2} : \frac{r'^3}{T'^2}$.

For by the principles of central forces,

$$F : F' :: \frac{r}{T^2} : \frac{r'}{T'^2};$$

and ſince we ſuppoſe the attractive force of the planet upon its ſatellite to vary inverſely, as the ſquare of the diſtance

$$F' : f :: r^2 : r'^2.$$

Multiplying theſe two proportions, and dividing by F′,

$$F : f :: \frac{r^3}{T^2} : \frac{r'^3}{T'^3};$$

but $F : f$, are the attractive forces of the ſun and planet, upon a particle of matter, placed at equal diſtances, and are evidently proportionate to the maſſes. Therefore, $M : M' :: \frac{r^3}{T^2} : \frac{r'^3}{T'^2}$.

Example.—To find the maſs of Jupiter.

$r : r' :: 63662 : 7964.7,$
$T : T' :: 365.256 : 16.689.$

Therefore $M : M' \frac{(63662)^3}{(365.256)^2} : \frac{(7964.7)^3}{(16.689)^2} :: 1 : \frac{1}{1066.08}$.

But, as the force which retains Jupiter in its orbit, is the ſum of the attractions of Jupiter and the ſun, the denominator muſt be increaſed by unity, and the maſs of Jupiter will be $\frac{1}{1067.08}$.

In the ſame manner, La Place finds Saturn $\frac{1}{3359.4}$.

The Georgian $\frac{1}{19504}$.

The ſecond method conſiſts in determining the diſtance which a planet (as the earth) deflects from its tangent in one ſecond, by comparing its angular velocity, with the mean radius of its orbit; and having found by experiment the ſpace which a heavy body deſcribes in one ſecond by the force of gravity at the ſurface of the planet, we can compute the ſpace it would fall through in the ſame time, if removed to the diſtance of the ſun, and ſince at equal diſtances the attractive force is proportionate to the maſſes, we can deduce the ratio of the maſſes from that of the attractive forces. By this method the maſs of the earth is found to be $\frac{1}{329630}$ that of the ſun.

The maſſes of Venus and Mars have been eſtimated by the ſecular variation which thoſe bodies produce on the ſolar ſyſtem. La Place concludes the maſs of Mars $\frac{1}{1846082}$, and that of Venus $\frac{1}{383137}$, the ſun being unity. Theſe quantities were obtained by the ſecular diminution of the obliquity of the ecliptic, and from the acceleration of the mean motion of the moon.

The denſities of ſpherical bodies are, as their maſſes, divided by the cubes of their ſemi-diameters.

The diameters of the planets being found by obſervation, and their maſſes by the above methods, the denſities of the planets appear to be as follows:

Sun	1.0000
Earth	3.9393
Jupiter	0.8601
Saturn	0.4951
Georgian	1.1376

Mr. Vince, in his Aſtronomy, gives us the following method of finding the denſities of the planets:

Put d = the denſity of the central body,
m = its diameter,
a = its quantity of matter,
P = the periodic time of the revolving body,
D = the mean diſtance of the revolving body from its central body,
S = the ſine of the angle under which m appears at the diſtance D, to radius unity.

Then a varies as $d m^3$, but P^2 varies as $\frac{D^3}{a}$, which varies as $\frac{D^3}{d m^3}$, hence d varies as $\frac{D^3}{m^3 P^2}$. But $S = \frac{m}{D}$; hence d varies as $\frac{1}{S^3 P^2}$, we will therefore aſſume $d = \frac{1}{S^3 P^2}$.

For the ſun.—If we take the earth as the revolving body, P = 365, 25639 days, according to M. de la Caille s = ⊙.0093155 = ſin. 32′, 1″, 5, the mean apparent diameter of the ſun, hence $d = \frac{1}{0.0093155^3 \times 365.25639^2} =$ 9.2722.

For the earth.—Here we muſt take the moon for the revolving body, therefore P = 27.32167 days according to Mayer, S = 0.033155 = ſin. 1° 54′, the mean angle under which the earth's mean diameter appears at the moon, hence $d = \frac{1}{0.033155^3 \times 27.32167^2} = 36.7569.$

For Jupiter.—Mr. Pound has obſerved the greateſt elongation of its fourth ſatellite to be 8′ 16″, and the correſponding diameter of Jupiter to be 39″, hence the ſine S of the angle under which the diameter of Jupiter appeared at that ſatellite at that time was 0.07869. Alſo P = 16.68898 days, according to M. Wargentin; hence $d = \frac{1}{0.07862^3 \times 16.68898^2} = 7.3857.$

For Saturn.—According to Mr. Pound, the greateſt elongation of its fourth ſatellite is 2′ 58″, and the correſponding diameter of Saturn = 18″; hence S = 0.10112. Alſo P = 15.9454 days, according to Dr. Halley, hence $d = \frac{1}{0.10112^3 \times 15.9454^2} = 3.8038.$

For the Georgian.—If we take the ſecond ſatellite, we have, according to Dr. Herſchel, its greateſt elongation = 44″.23, and the correſponding diameter of the planet =3″.90554,

$= 3''.90554$, hence S = 0.0883. Alſo P = 13.462 days, hence $d = \frac{1}{0.0883^3 \times 13.462^2} = 8.0149$.

The denſity of Venus was computed, by Dr. Maſkelyne, to be 1.024. M. de la Lande makes it 1.038.

The denſities of the planets, determined by this method, will be nearly as follows:

Sun	0.25226
Mercury	2.58330
Venus	1.02400
Earth	1.00000
Mars	0.65630
Jupiter	0.20093
Saturn	0.10349
Georgian	0.21805

Denſity of the Earth.

In the above computations, the ſun or the earth hath been aſſumed as the unity, from which the other denſities have been computed.

But it is a queſtion of no leſs intereſt to know the denſity of the earth itſelf, relatively to ſome known ſubſtance, for inſtance, water, which is what we uſually take as a ſtandard of compariſon, when we conſider the ſpecific gravities of other bodies.

Dr. Maſkelyne, the preſent aſtronomer royal, was the firſt perſon that determined experimentally the denſity of the earth by meaſuring the attractive force of the mountain Schehallien, on the plumb-line of a zenith ſector. He inferred the actual mean denſity of the earth to that of water as $4\frac{1}{2}$ to 1. The data for this determination were ſomewhat uncertain, as it was requiſite to have given the internal ſtructure of the mountain, which could not be known but by conjecture.

But the late experiments of Mr. Cavendiſh have left us very little uncertainty upon this ſubject; he concludes the mean denſity of the earth to be $5\frac{1}{2}$ greater than water.

The experiment of Mr. Cavendiſh is founded on the ſame principle as that of Dr. Maſkelyne; the reader will find a very minute deſcription of every part of the proceſs in the Philoſophical Tranſactions, for 1798, from which we can only give an extract of the more material circumſtances. To render the object of the experiment more intelligible, it may not be improper to give a ſhort explanation of the principle on which it is founded.

If a ball *a* (*Plate* IX. *Aſtronomy*, *fig.* 60.) be ſuſpended by a thread in the manner of a pendulum, and a large ball A, be placed on one ſide of it, if the attraction of A be ſenſible on the ſmaller ball, it will be deflected from its vertical poſition and will aſſume a new one, as *á*, where it will remain in equilibrio. And as it is demonſtrated by the elementary principles of mechanics, that the attractive power of the ball A is to the attractive power of the earth as the arc *aá* is to radius: therefore when we know the attractive power of 100 weight of lead, for inſtance, at the diſtance A *a*, we can calculate how many hundred weight muſt be placed at 4000 miles diſtance, or at the centre of the earth; to retain the ball in equilibrio at *á*, this weight is evidently that of the whole earth. Now to render the ſmall arc *a á* ſenſible, it is evident we muſt either have a pendulum of an exceſſive length, or the ball A of an enormous weight.

In Dr. Maſkelyne's experiment the latter circumſtance was choſen. The mountain repreſented the ball A, and the pendulum was the plumb-line of the zenith ſector; the former principle is adopted in that of Mr. Cavendiſh, and the ingenuity of the mechaniſm conſiſts in the ſubſtitution of a ſhort horizontal pendulum, equal in ſenſibility to a vertical one of immenſe length: for we ſhall find that the pendulum in the following experiments, vibrated only four times in an hour: now a pendulum ſuſpended vertically to have vibrated equally ſlow, and to have been therefore equally ſenſible to the attraction of the ball A, muſt have been between four and five hundred miles in length.

The apparatus conſiſts of a ſlender horizontal arm, about ſix feet long, having at its extremities two ſmall leaden balls of two inches diameter; this is ſuſpended by a fine wire 40 inches long, the whole incloſed in a narrow wooden caſe to defend it from wind. It is plain that if the wire is ſufficiently ſlender, a very minute force will be ſufficient to draw the balls on one ſide: for when left to themſelves they will aſſume a given poſition, in which they will remain at reſt, and upon being ſlightly deranged will vibrate, and their vibrations will be the quicker, as the tendency of the rod to aſſume a given poſition, is greater, which will entirely depend on the rigidity of the wire.

Small pieces of ivory, containing diviſions to the 20th parts of an inch are placed within the caſe; thoſe in the direction *a a''*, *b b''*, conſidered as plus; thoſe in the direction *a a'*, *b b'*, minus.

Two leaden weights about 508 *oz.* each, are brought by means of an apparatus without the caſe, into either of the poſitions W W, or *w w*, or they may be kept at right angles to the arm, in which caſe they have no tendency to produce motion in the ſmall balls *a* or *b*.

The object of the experiment is, next, to determine the time of the vibrations of the arm, and the angular deviation from its central poſition cauſed by the attraction of the leaden weights. The author, after deſcribing the apparatus, proceeds to give the minute detail of 17 ſets of experiments, of which the reſults were as follows:—

Experiments	Motion of Weight.	Motion of the Arm.	Ditto cor^{d}.	Times of Vibration.	Ditto cor^{d}.	Mean Denſity of the Earth.
1	0 to +	14.32	13.42			5.5
	+ to 0	14.1	13.17	14.55		5.61
2	0 to +	15.87	14.69			4.88

For

For the method of computing the denſity of the earth from theſe data, we ſhall give the author's own words.

"I ſhall firſt compute this on the ſuppoſition that the arm and copper rods have no weight, and that the weights exert no ſenſible attraction, except on the neareſt ball, and ſhall then examine what corrections are neceſſary on account of the arm and rods, and ſome other ſmall cauſes.

"The firſt thing is to find the force required to draw the arm aſide, which, as was before ſaid, is to be determined by the time of a vibration.

"The diſtance of the centres of the two balls from each other is 73.3 inches, and therefore the diſtance of each from the centre of motion is 36.65, and the length of a pendulum vibrating ſeconds in this climate is 39.14. Therefore if the ſtiffneſs of the wire by which the arm is ſuſpended is ſuch that the force which muſt be applied to each ball, in order to draw the arm aſide by the angle A, is to the weight of the ball as the arc of A to the radius, the arm will vibrate in the ſame time as a pendulum whoſe length is 36.65 inches, that is in $\sqrt{\frac{36.65}{39.14}}$ ſeconds; and therefore if the ſtiffneſs of the wire is ſuch as to make it vibrate in N ſeconds, the force which muſt be applied to each ball, in order to draw it aſide by the angle A, is to the weight of the ball as the arc of $A \times \frac{1}{N^2} \times \frac{36.65}{39.14}$ to the radius. But the ivory ſcale at the end of the arm is 38.3 inches from the centre of motion, and each diviſion is $\frac{1}{20}$th of an inch, and therefore ſubtends an angle at the centre, whoſe arc is $\frac{1}{766}$; and therefore the force which muſt be applied to each ball, to draw the arm aſide by one diviſion, is to the weight of the ball as $\frac{1}{766N^2} \frac{36.65}{39.14}$ to 1, or, as $\frac{1}{818N^2}$ to 1.

"The next thing is to find the proportion which the attraction of the weight on the ball bears to that of the earth thereon, ſuppoſing the ball to be placed in the middle of the caſe, that is, not to be nearer to one ſide than the other. When the weights are approached to the balls, their centres are 8.85 inches from the middle line of the caſe; but through inadvertence, the diſtance from each other of the rods which ſupport theſe weights, was made equal to the diſtance of the centres of the balls from each other, whereas it ought to have been ſomewhat greater. In conſequence of this, the centres of the weights are not exactly oppoſite to thoſe of the balls when they are approached together; and the effect of the weights in drawing the arm aſide, is leſs than it would otherwiſe have been in the triplicate ratio of $\frac{8.85}{36.65}$ to the chord of the angle, whoſe ſine is $\frac{8.85}{36.65}$, or in the triplicate ratio of the coſine of half this angle to the radius, or in the ratio of .9779 to 1.

"Each of the weights weighs 2,439,000 grains, and therefore is equal in weight to 10.64 ſpherical feet of water. And therefore its attraction on a particle placed at the centre of the ball, is to the attraction of a ſpherical foot of water, on an equal particle placed on its ſurface, as $10.64 \times .9779 \times \left(\frac{6}{8.85}\right)^2$ to 1. The mean diameter of the earth is 41800000 feet, and therefore if the mean denſity of the earth is to that of water as D to 1, the attraction of the leaden weight on the ball will be to that of the earth

thereon, as $10.64 \times .9779 \times \left(\frac{6}{8.85}\right)^2$ to 41800000 D :: 1 to 8739000 D.

"It is ſhewn therefore, that the force which muſt be applied to each ball, in order to draw the arm one diviſion out of its natural poſition, is $\frac{1}{818\,N^2}$ of the weight of the ball; and if the mean denſity of the earth is to that of water, as D to 1, the attraction of the weight on the ball is $\frac{1}{8739000\,D}$ of the weight of that ball: and therefore the attraction will be able to draw the arm out of its natural poſition by $\frac{818\,N^2}{8739000D}$, or $\frac{N^2}{10683\,D}$ diviſions: and therefore, if on moving the weights from the midway to a near poſition, the arm is found to move B diviſions, or if it moves 2 B diviſions, on moving the weights from one near poſition to the other, it follows that the denſity of the earth, or D, is $\frac{N^2}{10683\,B}$."

The remaining part of the paper of Mr. Cavendiſh is filled with the calculations neceſſary to find the corrections which are added to the table of experiments.

Theſe being applied, and a mean taken of all the experiments, the author concludes the mean denſity of the earth to be 5.48 times greater than that of water.

DENTAL, Dentalis, from *dens*, a *tooth*, is applied to certain letters, in the pronunciation whereof the teeth have a principal ſhare.

Grammarians, and eſpecially the Hebrew ones, diſtinguiſh the letters into dental, labial, guttural, lingual, palatal, &c.

DENTALIS, in *Anatomy*, a term which has been applied to the nerves and blood-veſſels of the teeth.

DENTALIUM, in *Conchology*, a genus of univalves of a tubular form, ſtraight or only ſlightly curved, with an undivided cavity open at both ends. Animal a terebella.

Species.

Elephantinum. Shell with ten ribs, ſlightly curved and ſtriated. Linn.—*Denticulus elephanti*, Rumpf.—*Dentalis*, Argenv.

Inhabits the Indian and European ſeas, and is about four inches long; the ſhell is deeply grooved, green with the tip white.

Aprinum. Shell with ten ribs, ſlightly incurved and ſmooth. Mart.

Native of the ſame ſeas as the former, and is by ſome conſidered as a variety.

Arcuatum. Shell ribbed, curved, ſubulate, and of one colour. Gualt. Country unknown; colour greeniſh.

Striatulum. Shell with eight ribs and eight ſtriæ; tip acute, green and tipped with white. Mart. Native of the Sicilian ſeas.

Sexangulum. Shell with ſix ribs and ſtriated. Schroet. Diſcovered in a foſſil ſtate at Loretto.

Dentalis. Shell with twenty ſtriæ, ſlightly curved and interrupted. Rumpf.

Found in the Mediterranean, and is ſometimes red, or reddiſh at the tip.

Entalis. Shell round, ſlightly curved, continued and ſmooth. Linn. Donov. Brit. Shells, &c. Native of European ſhores; about an inch and half in length.

Arietinum. Shell round, curved, continued, and ſmooth. Müll.

Inhabits the ſhores of Scandinavia; reſembles the laſt, but is much ſmaller.

Corneum. Shell round, ſlightly curved, interrupted and opake. Schroet.

Length an inch and a quarter. This ſhell is ſmooth, horny, yelloviſh brown, with an obtuſe rounded tip, and inhabits the African ocean.

Politum. Shell round, ſlightly curved, continued, and marked with crowded annular ſtriæ. Gualt.

Native of Indian and European ſeas, and meaſures about an inch and a half in length.

Eburneum. Shell round, ſlightly curved, continued, and marked with remote annulations. Gmel. Inhabits the ſame country as the former.

Minutum. Shell round, ſtraightiſh, ſmooth, and minute. Plancus. Native of the Mediterranean.

Faſciatum. Shell very finely ſtriated, ſlightly curved, and grey, with darker bands. Martini.

Inhabits Sicily. This ſhell is minute, ſolid, and marked with about four or five duſky cinereous or fuſcous bands.

Nebulosum. Shell arcuated, very ſmooth and white, ſpotted and clouded with fulvous. Gmel. Native of the Sicilian ſeas.

Rectum. Shell ſtraight, with double or triple ſtriæ, and annulated. Gualt. Country unknown.

Fossile. Shell roundiſh, and ſomewhat obtuſe, with very fine equal ſtriæ. Schroet. Found foſſil near Loretto.

Annulatum. Shell round and obliquely ſtriated. Guettard. Occurs in a foſſil ſtate.

Radula. Shell ſomewhat arched and rather obtuſe, with decuſſate ſtriæ, the longitudinal ones granulated. Schroet. Found in the ſame ſtate as the former in Piedmont. Length one inch.

Pellucidum. Shell horny, flexile, ſtraightiſh, round and ſmooth. Schroet.

Native of the Northern ſeas. The length is two inches and a quarter; colour pale honey.

Interruptum. Shell with decuſſating ſtriæ, all which are ſmooth; the longitudinal ſtriæ with finer interrupted ones. Schroet.

This and the following are found in a foſſil ſtate in Piedmont.

Vitreum. Shell hyaline, very glabrous and ſubarcuated. Schroet.

DENTARIA, in *Botany*, (from the toothed ſtructure of the root, whence it has been ſuppoſed, without any real foundation, to be uſeful in diſorders of the teeth.) Toothwort, or Coral-wort, Linn. Gen. 337. Schreb. 441. Willd. Sp. Pl. v. 3. 478. Juſſ. 239. Claſs and order, *Tetradynamia Siliquoſa*. Nat. Ord. *Siliquoſæ*, Linn. *Cruciferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of four leaves, which are ovate-oblong, cohering longitudinally, obtuſe, deciduous. *Cor.* cruciform. Petals four, roundiſh, obtuſe, ſcarcely emarginate, flat, with claws as long as the calyx: nectary four glands at the baſe of the germen. *Stam.* Filaments ſix, awl-ſhaped; four of them as long as the calyx, two ſhorter; anthers oblong-heart-ſhaped, erect. *Piſt.* Germen oblong, the length of the ſtamens; ſtyle very ſhort and thick; ſtigma obtuſe, emarginate. *Peric.* Pod long, round, of two cells and two elaſtic valves, which roll back when ripe; partition a little longer than the valves. *Seeds* numerous, ſomewhat ovate.

Eſſ. Ch. Pod burſting elaſtically, the valves rolling back, ſhorter than the partition; ſtigma emarginate; Calyx-leaves cohering longitudinally.

Seven ſpecies are deſcribed in Willdenow; three only were known to Linnæus. The roots of all, as far as we are informed, are perennial, fleſhy, white, notched in ſuch a manner as to reſemble the human fore teeth. Stem ſimple, herbaceous. Leaves compound, ſerrated, ſmooth. Flowers in a terminal corymb, purpliſh, or white, large and handſome, reſembling thoſe of *Lunaria* or Honeſty. 1. D. *enneaphylla*. Linn. Sp. Pl. 912. Jacq. Auſtr. t. 316. Leaves three together, ternate, ſerrated, without any glands between the leaflets. A native of Auſtria and Italy, in mountainous ſtony places. Flowers pale yelloviſh. 2. D. *glandulosa*. "Leaves three together, ternate, deeply toothed, with an awl-ſhaped gland between their leaflets. Stamens half as long as the corolla." Willd. Sp. Pl. v. 3. 478. Found by Waldſtein and Kitaibel in Hungary, and diſtinguiſhed by Willdenow from the former. Flowers purple, larger. Leaves narrower. 3. D. *laciniata*. Willd. 479. Leaves three together, ternate, bluntiſh, toothed; lateral leaflets deeply divided. This, a native of Pennſylvania, was originally ſent by Kalm to Linnæus, who took it for his own D. *pentaphyllos*, a ſpecies he had adopted from authors without ſeeing it, but which is a very different and much larger plant. 4. D. *bulbifera*. Bulbiferous Coral-wort. Linn. Sp. Pl. 912. Engl. Bot. t. 309. Lower leaves pinnate; upper ones ſimple. A native of ſome places in the middle and ſouth of England, as at Harefield, Beaconsfield, Tunbridge, &c. but a doubtful Swiſs plant. Known by ſcaly purple *gemmæ* or buds produced in the boſoms of its leaves, by which it is propagated like the *Lilium bulbiferum*, and like that it conſequently ſeldom perfects ſeed. 5. D. *micraphylla*. "Leaves all pinnate; leaflets linear-lanceolate, unequally toothed. Willd. 479. Known only by Willdenow's account, who had it from Siberia, and compares its leaves to the *Cardamine*, v. 3. t. 65. of Gmelin's Sib. Flowers purple, but with narrower petals than in the following, of which Willdenow ſuſpects it may be a variety. 6. D. *pinnata*. Lamarck Encycl. v. 2. 268. Ait. H. Kew. v. 2. 386. Willd. 480. (D. pentaphylla α, Linn. Sp. Pl. 912. D. heptaphyllos. Cluſ. Pann. 453. Garid. Prov. t. 28. Ger. em. 985. Geſn. Faſc. t. 1. f. 2.) Leaves all pinnate; leaflets lanceolate, pointed, acutely ſerrated. Found in the Alps of France and Switzerland. A very large and handſome ſpecies, confounded by Linnæus and Haller with the following. The flowers are uſually of a light roſe-colour. 7. D. *pentaphyllia*. Linn. Sp. Pl. 912, β and γ. Willd. 480. Leaves digitate; leaflets five. Of this there are two ſuppoſed varieties, both natives of the Alps of Switzerland. The β of Linnæus is Dentaria 7, Cluſ. Hiſt. v. 2. 122. f. 2; (Geſn. Faſc. t. 1. f. 1, B; Camer. Epit. 704.) This has the root very remarkably and acutely toothed, and the leaves are ſaid to be ſmooth. The γ of Linnæus is Dentaria 6, Cluſ. Hiſt. v. 2. 122. f. 1; (Geſn. Faſc. t. 1. f. 1, A; Bauh. Hiſt. v. 2. 901.) In this the root is rather knotty and as it were jointed, *nodoſo-articulata*, than toothed, and the leaves are deſcribed rough to the touch. Garidel's tab. 29, though taken by him for the former, appears by the root to be this variety. There is the greateſt reaſon to believe theſe two diſtinct ſpecies, though ſince Caſpar Bauhin united them, no botaniſt has ſeparated them, nor have we materials ſufficient for the purpoſe. They deſerve the attention of the curious botaniſt, and are worthy of a place in our gardens.

Dentaria. See Lathræa, Tozzia, and Orobanche.

Dentaria, in *Gardening*, affords plants of the herbaceous flowery, hardy, perennial kind; of which the ſpecies cultivated

cultivated are the five-leaved dentaria, or tooth-wort (D. *pentaphylla*), bulbiferous dentaria, or coral-wort, (D. *bulbifera*.)

The firſt ſort riſes with a ſtrong ſtalk a foot and a half high, with a leaf at each joint, compoſed of five lobes, four inches long, and near two broad in the wideſt part, ending in acute points, and deeply ſerrate; they are ſmooth, and ſtand on long footſtalks; the flowers grow in looſe ſpikes at the top of the ſtalks, are ſmall, and of a bluſh colour. It is a native of Switzerland, &c.

The ſecond kind has a perennial root: the ſtem is ſimple, a foot in height; the lower leaves have three pairs of leaflets, and an odd one, which is confluent with the pair below it; they are bluntly lanceolate and ſerrate; the leaves above theſe have five leaflets, and the upper leaves are trifid or ſimple, acutely lanceolate, ſerrate; the flowers are in cluſters on the tops of the ſtalks, and fleſh-coloured or purple. The ſcaly bulbs in the axils of the upper leaves, falling off, take root, and propagate new plants; ſo that it rarely produces ſeed. It is a native of Sweden, flowering in April and May.

Method of Culture.—In theſe plants the propagation is effected by ſowing the ſeeds in a light ſandy ſoil, where the ſituation is ſhaded, either in the autumn, as ſoon as they are perfectly ripened, or in the early ſpring. The former is the better ſeaſon, where the ſoils are ſufficiently dry. They are alſo capable of being increaſed by parting the roots and planting them out, where there is a due degree of moiſture and ſhade, in the autumn or ſpring; and in the latter ſort they may be raiſed by planting the bulbs produced on the ſides of the ſtems.

Afterwards, the only culture the plants ſtand in need of, is that of keeping them clean from weeds, and in the firſt method removing ſuch plants as may be too much crowded to proper ſituations in the ſpring. They moſtly flower and produce ſeeds in the ſecond year's growth.

Theſe are a ſort of plants which are well adapted to the borders and other parts of ſhady walks, and other ſimilar compartments; where they grow well, and have an ornamental effect, as well as afford variety.

DENTATA Vertebra, in *Anatomy*, the ſecond vertebra of the neck; ſo called from a peculiar proceſs, which it poſſeſſes. See Spine.

DENTATUM Folium. See Leaf.

DENTED, Indented, *toothed*. See Indented.

Dented *Wheel*, in *Mechanics*. See Wheel.

DENTELLA, in *Botany*, (in alluſion to the minute teeth of the corolla, on which the generic character is founded.) Forſt. Gen. 13. t. 13. Schreb. 124. Willd. Sp. Pl. v. 1. 972. Juſſ. 200. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, in five deep awl-ſhaped ſegments. *Cor.* of one petal, funnel-ſhaped, longer than the calyx; tube gradually dilated upwards; limb regular, in five equal ſpreading ſegments, each of them with three acute teeth, the middle one of which is the longeſt. *Stam.* Filaments five, equal, ſhort, awl-ſhaped, inſerted into the baſe of the tube; anthers oblong, erect. *Piſt.* Germen inferior, roundiſh, hairy; ſtyle cylindrical, ſhort, and thick; ſtigmas two, ſpreading, obtuſe, longer and thicker than the ſtyle. *Peric.* Capſule globoſe, of two cells, crowned with the calyx. *Seeds* ſeveral, ovate.

Eſſ. Ch. Calyx ſuperior, in five deep ſegments. Corolla funnel-ſhaped, in five ſegments, each with three teeth. Capſule of two cells, with many ſeeds.

The only known ſpecies is D. *repens*; Forſt. Prod. 17. Willd. Sp. Pl. v. 1. 972. (Oldenlandia repens; Linn. Mant. 40. Burm. Ind. 38. t. 15. f. 2, very bad, with an erroneous ſynonym from Hort. Mal. v. 10. t. 31. Alſine ſpergula ind. or. &c.; Pluk. Amalth. 10. t. 356. f. 5. Cruſta ollæ minima; Rumph. Amboin. v. 6. 460. t. 170. f. 4, good.) A native of various parts of the Eaſt Indies; found by Forſter in New Caledonia. It is ſaid by Rumphius to be a weed in the gardens of Amboyna, and by Burmann to grow in wet places at the coaſt of Coromandel. Root annual, according to Burmann. Stems ſeveral, proſtrate, branched, leafy, ſquare, ſmooth, taking root at their joints. Leaves oppoſite, ſtalked, elliptic-lanceolate, entire, ſmooth, reſembling thoſe of thyme. Flowers axillary, ſolitary, nearly ſeſſile. Corolla rather longer than the leaves, ſlender, white, often with a purpliſh tinge. Capſule nearly globular, the ſize of a pepper-corn, clothed all over with prominent, jointed, obtuſe, pellucid hairs, which render it very conſpicuous and remarkable. The plant is not known in our gardens, nor has it been found of any uſe.

DENTELLARIA. See Plumbago *Europæa*.

DENTES, in *Anatomy*. See Cranium and Teeth.

Dentes *lactei*, or *decidui*, the firſt, or temporary ſet of teeth; for an account of which, ſee Cranium.

DENTEX, in *Ichthyology*, a ſpecies of *Sparus*; which ſee.

DENTICI, Luigi, in *Biography*, a Neapolitan gentleman, who publiſhed at Rome, in 1553, two dialogues on muſic. Of theſe, though the ſubject turns chiefly upon the muſical proportions, and modes of the ancients; in attempting to explain which, Boethius ſeems to have been the author's principal guide; yet, in the ſecond dialogue, we have an account of what was then a *modern* concert, from which an idea may be formed of the ſtate of practical muſic at Naples, when this book was written. One of the interlocutors, ſpeaking with rapture of a performance which he had heard at the palace of Donna Giovanna d'Arragona, tells us that the principal muſicians who played on inſtruments, and were of the firſt claſs, were Giovan Leonarda de l'Harpa Napolitano, Perino da Firenze, Battiſta Siciliano, and Giaches da Ferrara; and that the ſingers were Giulio Ceſare Brancazzo, Franciſco Biſballe, Conte de Briatico, Scipione di Palla, and a ſoprano, whoſe name, as his performance was cenſured, the author has concealed; but of the others, he ſays, they were moſt perfect muſicians, and ſung in a wonderful manner. It appears by this dialogue, that the vocal performers were not accompanied by a band, but that each ſung to his own inſtrument. "Pochi muſice ſi travano che cantono ſopra gli ſtormenti che m'abbian finito di contentare, perche tutti errano in qualche coſa, o nella intonatione, o nella pronontiatione, o nel ſuonare, o nel fare i paſſaggi, a vero nel remettere & rinforzare la voce quando biſogna; le quali coſe, parte per arte & parte per natura s'acquiſtano." "There are few muſicians," ſays the author, "who ſing to their inſtruments, that have entirely ſatisfied me: as they have almoſt all ſome defect of intonation, utterance, accompaniment, execution of diviſions, or manner of diminiſhing and ſwelling the voice occaſionally; in which particulars both art and nature muſt conſpire to render a performer perfect." The interlocutors then celebrate the talents of two female ſingers: Donna Maria di Cardona Marcheſe della Padula, and Signora Fagiola, as being poſſeſſed of all the requiſites of vocal perfection.

It may be concluded from this converſation, that the ſoprano among the male ſingers was an evirato; that much art and refinement were expected in vocal performers, beſides ſinging in time and tune; and that, by the titles of count

and marchioneſs given to ſome of the perſonages whoſe talents are celebrated, whether they are regarded as profeſſors or diletanti, it appears that the ſucceſsful cultivation of muſic in the city of Naples was at this time in great eſtimation.

DENTICLES, in *Architecture*. See DENTILS.

DENTIDIA, in *Botany*, a Chineſe plant, of which we have no knowledge but from Loureiro's Flora Cochinchinenſis, 369. He deſcribes it as belonging to the *Didynamia Gymnoſpermia*, and gives the following Eſſ. Ch. Three upper ſegments of the calyx minutely toothed. Upper lip of the corolla ſhorteſt, four-cleft; lower entire. D. *nankinenſis* is the only ſpecies, a native of Nankin, carefully cultivated at Canton for its beauty, and called *Kiām năn tſū ſū*. It has the colour and ſcent of *Meliſſa cretica*. The ſtem is herbaceous, annual, upright, a foot high; firm, ſquare, ſtraight, purple, ſmooth, with branches croſſing each other. Leaves oppoſite, on long ſtalks, kidney-ſhaped, concave, reflexed, ſmooth, fringed, of a browniſh purple hue. Spikes axillary, ſquare. Flowers red and white. Loureiro. It is very probable this plant may belong to ſome genus already known. The deſcription accords in many points with *Perilla ocymoides*, Linn. which is a native of China.

DENTIFORM, in *Mineralogy*, according to Werner, is the form in which metallic or native ſilver is often found, where it is longiſh and tortuous, and thicker at the bottom than the top, where it ends in a point.

DENTIFORMIS PROCESSUS, the ſame as *Pyrenoides*.

DENTIFRICE, any ſubſtance to rub the teeth with, in order to clean or faſten them. The term is derived from the Latin *dens*, *a tooth*, and *frico*, *I rub*.

Dentifrices are commonly employed in the form of powder, which are either purely mechanical or chemical in their operation. It is uſual for dentiſts to keep their tooth-powders as a ſecret; but the compoſition of moſt of them is very well known to medical men, though concealed from the public in general. Very little ſkill is required to form a good tooth-powder for ordinary uſe, provided care be taken not to admit ingredients which deſtroy the enamel of the teeth. If perſons uſe them daily, the dentifrices ſhould be leſs harſh or gritty, and contain leſs acid matter, than when they are uſed only once a week.

The powders generally recommended for this purpoſe are, levigated coral, calcareous earths, cuttle-fiſh, myrrh, calcined bone, burnt bread or ſponge, charcoal, pumice-ſtone, ſoot, &c. to which is added a ſmall proportion of alum, cream of tartar, or common ſalt. But the acid ſubſtances uſed too freely will deſtroy the teeth, and compenſate badly for the whiteneſs they produce.

Any of the above powders may be mixed up with honey or butter, and will then form a kind of electuary for rubbing the teeth. Spirituous and aſtringent lotions are alſo employed with the ſame view, or to harden the gums; and not unfrequently the powder of caſcarilla, or Peruvian bark, is had recourſe to, when the gums are ſpongy and apt to bleed.

Many perſons are ſo averſe from all dentifrices, that they clean their teeth with a hard bruſh alone, or the end of a root prepared on purpoſe, rinſing their mouth afterwards with water. Now and then, however, it is requiſite to ſcrape the tartareous matter from the roots of the teeth, which is called *ſcaling* them; elſe, it will be impoſſible to preſerve their natural whiteneſs, and keep them fixed cloſely to the gums. The tartar is alſo injurious in decaying the teeth, when it accumulates for a long time. See TEETH.

DENTILS, in *Architecture*, an ornament in cornices of a notched or toothed form; whence its name, from *dentes*, Lat. teeth. (See *Plates* XXVIII. XXIX. of *Architecture*.) The dentils are cut upon a ſquare member, which is called by Vitruvius denticulus, and by Engliſh authors dentil-band. The proportions are thus given by the former writer; the denticulus is to be equal in height to the middle facia of the architrave, and its projection to be the ſame as the height; the width of the dentils is one-half of the height, and the interval between them two-thirds of this quantity.

DENTISCALPRA, in *Surgery*, is the ſcraping inſtrument employed for removing the extraneous matter which collects upon teeth, and forms a cruſt. The tartar, which is left on the teeth, where this operation has been long neglected, will ſometimes ſeparate the gums, produce ſome degree of ulceration, and cauſe a fœtid breath. See DENTIFRICE and TEETH.

DENTIST, is an artizan who confines himſelf to the extraction of teeth, and to ſeveral operations required by their defects, redundancies, accidents, or diſorders. The word dentiſt is French, and the moſt popular practitioners in this department have come from France; ſo, likewiſe, have the moſt ample and regular treatiſes on the ſubject, ſome of which are tediouſly prolix and frivolous. The head ſurgeons in London deem this branch of their art beneath notice, and generally decline interfering in it, except by giving their advice occaſionally: though manual operations on the teeth, and the mechanical formation of theſe organs, in caſes of defect, conſtitute a very profitable buſineſs in ſuch a large metropolis; ſo that dentiſts are often known to get ſeveral thouſand pounds *per annum* by their profeſſion!!

DENTITION, in *Anatomy*, the proceſs by which the teeth, after they have advanced to a certain ſtage of their formation, come through the gum, in order to take their place in the mouth. As there are two different ſets of teeth contained in the mouth at different ages, and accommodated, by their ſize and number, to the differences which obtain in the jaw-bones of the child and the older ſubject, ſo we have the firſt and the ſecond dentition. As the gum appears to be divided by the tooth in this proceſs, it is uſually called, in common language, the cutting of the teeth. The age at which each tooth comes through the gum, and the ſucceſſion in which theſe organs appear in both dentitions, have been already fully detailed in the deſcription of the teeth given under the article CRANIUM. We have only to obſerve, further, in this place, that the gum makes way for the advancing tooth by a proceſs of abſorption. That the tooth, in coming towards the alveolar ſurface of the jaw, is reſiſted by the gum, which is a firm and tough ſubſtance, and is thrown into a ſtate of conſiderable tenſion by the preſſure which it experiences. Being of a vaſcular and ſenſible nature, it is irritated in this way, and conſiderable pain enſues, with more or leſs derangement of the whole conſtitution. The latter often proceeds ſo far as to terminate fatally; and, conſequently, the time of the firſt dentition is regarded as one of particular danger to the child. That all this miſchief ariſes merely from the irritation cauſed by the preſſure of the tooth, is rendered obvious from this circumſtance; that it will ceaſe entirely if the gum be divided. The part grows thinner and thinner, where it is preſſed by the tooth, and a perforation takes place at laſt, through which the projecting edge or point may be diſcerned; and then the proceſs is finiſhed, without any further unpleaſant occurrences. The ſecond dentition is not attended with the ſame circumſtances as the firſt; ſince the permanent teeth come into places left for them by the temporary ones.

DENTITION.

Dentition, in *Phyſiology* and *Medicine*, the production of the teeth.

The time and mode of the formation and growth of the teeth have been amply treated of under the article Cranium. It remains for us to deſcribe, in this place,

The Diſeaſes of Dentition.—The teeth at their firſt formation, and for ſome time while growing, are completely incloſed within the ſockets and gums, and in their growth they act upon the incloſing parts, in ſome degree, as extraneous bodies. Hence, while the operation of growth is going on in them, another operation is effected, namely, a decay of that part of the gum and ſocket that covers the tooth, in conſequence of the preſſure of the latter, and which becomes the cauſe of many diſagreeable and even dangerous ſymptoms. This preſſure induces inflammation and ulceration of the gums, but ſuppuration ſeldom accompanies it. Hunter on the Teeth, part ii. p. 114.

As theſe morbid changes take place at an early age, indeed almoſt begin with life, when the irritability of the whole ſyſtem is extremely great, the ſymptoms which enſue are not merely local, but affect the conſtitution at large in various ways, and excite a great variety of maladies. Theſe ſymptoms are in fact ſo various in different children, and often in the ſame child, that it is difficult to conceive them to be of the ſame origin. They become leſs various, however, and leſs hazardous, as the children advance in age; ſo that the double teeth of the child, and ſtill more ſo the ſecond ſet of teeth, or thoſe of the adult, are uſually cut without producing much diſturbance.

The firſt ſymptoms are local, and appear to be accompanied with pain, as the child is reſtleſs, uneaſy, and rubs his gums, and carries every thing to his mouth. There are alſo generally inflammation, heat, and ſwelling of the gums, and an increaſed flow of ſaliva. A general ſtate of fever follows, which is ſometimes ſlight and ſometimes violent, and is very remarkable both for its ſudden riſe and declenſion: ſo that in the firſt hour of his illneſs the child ſhall be perfectly cool, and in the ſecond flaſhed and burning hot, and in the third temperate again. The local ſymptoms which enſue in diſtant parts, are various and complicated; for the appearance they put on is in ſome degree determined by the nature of the parts which they affect. Theſe ſymptoms we ſhall deſcribe in the order of their moſt frequent occurrence.

Diarrhœa, coſtiveneſs, loſs of appetite, eruptions on the ſkin, eſpecially on the face and ſcalp, cough, ſhortneſs of breath, with a kind of convulſed reſpiration, ſimilar to that obſervable in the hooping-cough, ſpaſms of particular parts, either by intervals or continued, an increaſed ſecretion of urine, and ſometimes a diminution of that ſecretion, a diſcharge of matter from the penis, with difficulty and pain in making water, imitating exactly a violent gonorrhœa. The lymphatic glands of the neck are at this time apt to ſwell, and if the child has a ſtrong tendency to the ſcrofula, this irritation will promote that diſeaſe. There may be other circumſtances connected with this diſorder, which we do not aſcertain, the patients in general not being able to expreſs their feelings.

Many of the ſymptoms of this diſeaſe are dangerous, namely, the conſtitutional ones, and alſo thoſe local ſymptoms which attack a vital part. The fever, indeed, ſeldom laſts ſo long as to be fatal; but the convulſions, eſpecially when univerſal, frequently are ſo. Local convulſions, if not in a vital part, although often very violent, do not kill; and when any part not vital ſympathizes, the patient is generally free from danger; a ſecurity to the whole being obtained by the ſufferings of a part, which is of little conſequence to life.

In the very irritable habits of infants a general ſympathy is excited by local irritations; and hence general fever and general convulſions, from the irritated gums in dentition. But as the conſtitution ſtrengthens, each part, in ſome degree acting for itſelf, acquires its own peculiarities; ſo that when a local diſeaſe takes place in a child that is very young, it is capable of calling forth a general ſympathy; but as the child advances, the conſent of parts in the conſtitution becomes leſs general: but ſome one part is found which has a greater aptitude than the reſt to fall in with the local irritation, and it ſympathizes according to its own peculiar action. By the age of ſix years, few parts ſuffer but thoſe immediately affected; and in adults, who cut their teeth, we almoſt always find the pain and other ſymptoms confined to the part, or only local ſympathy taking place, ſuch as a ſwelling of a ſide of the face.

But as the ſymptoms become more confined, the ſuffering part is often much more violently affected. Therefore we find that, in adults, the pain of cutting a grinder is frequently exceſſive, and the local inflammation is very conſiderable, and often of long continuance. This is not the caſe with children; their pain does not appear to be ſo very conſiderable, and we are certain that the local inflammation is not great; that it is confined to the very parts which ſuffer, and is not diffuſed over the face; ſo that, in children, the ſymptoms of ſympathy are often more violent than thoſe of the parts themſelves.

The pains from dentition in the adult are often periodical, having their regular and fixed periods, from which circumſtance they are often ſuppoſed to be agueiſh, and the bark is adminiſtered, but without effect. Medicines for the rheumatiſm are likewiſe given with as little ſucceſs; when a tooth will appear, and diſcloſe the cauſe of the complaint: and by lancing the gums the cure is often performed; but the diſeaſe will recur, if the gum happens to heal over the tooth, which it will very readily do, if the tooth is pretty deep. As theſe teeth are generally ſlower in their growth than the others,, and more eſpecially thoſe which come very late, they become the cauſe of many returns of the ſymptoms.

The remedies for the diſeaſes ariſing from dentition can in general only be of a temporizing nature, as the diſorders cannot be altogether removed, till the cauſe ceaſes; except indeed, when the tooth is covered by a very thin portion of the gum, in which caſe the ſymptoms may be ſometimes ſpeedily removed by lancing it. Where this cannot be immediately done, and the general ſymptoms of fever, or convulſions, appear, palliative meaſures muſt be adopted. Gentle laxatives, if the bowels are bound, diaphoretics, and ſmall doſes of ſome anodyne, muſt be adminiſtered; and the uſe of the warm-bath muſt be added, as the moſt effectual anodyne, when convulſions occur. If a diarrhœa ſhould come on, and in a gentle degree only, it may be allowed to go on; or if ſevere, it may be reſtrained. But often the ſympathetic derangement of the bowels becomes itſelf an irritating cauſe, and by ſympathy with the brain, contributes to excite fever, and even convulſions. When, therefore, the bowels are much diſordered, when there is obviouſly much griping pain, when the ſtools are offenſive, and of a morbid appearance, they ſhould be cleared by a little calomel and rhubarb, or other laxatives. The uſe of laxative medicines is alſo particularly ſerviceable in removing the cutaneous eruptions, which appear during the irritation of teething; ſuch as the cruſta lactea, ſtrophulus, or red-gum, &c.

When the local inflammation is ſlight, it ſeems deſirable to gratify the inſtinctive propenſity, which children manifeſt, to rub and preſs the gums; and a piece of wax, or of liquorice root, or ſome ſubſtance of that ſoft kind, appears to be preferable to the hard, unyielding coral, or glaſs, which

is generally employed for that purpoſe. It would be altogether ſuperfluous to mention the numerous abſurd remedies, which ignorance and ſuperſtition have introduced, at different times, to aid the proceſs of dentition; and eſpecially as local applications to the gums. The reader will find them amply detailed in Henlock's Practical Treatiſe on Dentition, 1742. Perhaps a ſhort ſpecimen will ſatisfy him. "There were indeed among the remedies to the gums, ſome few that were in vogue; freſh butter and honey were in pretty general eſteem, perhaps for the toothſomeneſs of them above many others. The brain of a ſucking pig, and the milk of a bitch (whatever averſion this might raiſe in the parent) were commended by ſome for a peculiar property; but more particularly the brain of a hare, which ſeems to carry the univerſal applauſe of the ancients; yet the doubts among them about the beſt mode of uſing it, give reaſon to believe, that it was often recommended upon bare credit. But above all, in neceſſitous caſes, if we may depend upon rhe teſtimony of Hartman (as mentioned by Burnet) the freſh blood of a cock's comb is truly praiſeworthy; for this, ſays he, being only once, or twice at moſt, anointed on the gums with the finger, cauſes a production of the teeth without difficulty, and free from accidents. This we find alſo recommended by Silvius and Waldſchmidt." Loc. Cit. p. 33. All this, however, is ſcarcely leſs prepoſterous than the wearing of certain necklaces, in our own day, for the purpoſe of alleviating difficult dentition.

"With reſpect to lancing the gums, there was formerly much difference of opinion. But Mr. Hunter ſays, "As far as my experience has taught me, to cut the gum down to the tooth, appears to be the only method of cure. It acts either by taking off the tenſion upon the gum, ariſing from the growth of the tooth, or by preventing the ulceration, which muſt otherwiſe take place. It often happens, particularly when the operation is performed early in the diſeaſe, that the gum will re-unite over the teeth; in which caſe the ſame ſymptoms will be produced, and they muſt be removed by the ſame method. I have performed the operation above ten times upon the ſame teeth; where the diſeaſe had recurred ſo often, and every time with the abſolute removal of the ſymptoms.

"It has been aſſerted, that to cut the gum once will be ſufficient, not only to remove the preſent, but to prevent any future bad ſymptoms from the ſame cauſe. This is contradictory to experiment, and the known laws of the animal œconomy: for frequently the gum, from its thickneſs over the tooth, or other cauſes, muſt neceſſarily heal up again, and the relapſe is as unavoidable as the original diſeaſe. A vulgar prejudice prevails againſt the practice, from an objection, that if the gum is lanced ſo early, as to admit of a re-union, the cicatrized part will be harder than the original gum, and therefore the teeth will find more difficulty in paſſing, and give more pain. But this is alſo contrary to facts; for we find that all parts, which have been the ſeat either of wounds or ſores, are always more ready to give way to preſſure, or any other diſeaſe, which attacks either the part itſelf, or the conſtitution. Therefore each operation tends to make the paſſing of the teeth eaſier." Hunter on the Human Teeth, Part ii. p. 121. See INFANTS, *Diſeaſes of*.

DENTON, WILLIAM, in *Biography*, the youngeſt ſon of ſir T. Denton of Hilleſden, in Buckinghamſhire, was born at Stow, in April 1605. He received his education at Magdalen Hall in Oxford, where he was initiated into the practice of medicine, under Dr. Henry Aſhworth. In 1634 he took his degree of doctor, and going ſoon after to reſide in London, he was appointed phyſician to the king, Charles I. During the troubles which ſucceeded, he continued to practiſe in his profeſſion in London, but acted during that time with ſo much moderation, that on the reſtoration of Charles II. he was made one of his phyſicians in ordinary, and was ſoon after admitted fellow of the college of phyſicians. He lived to ſee another revolution, and the acceſſion of king William and queen Mary, to whom, in 1689, he dedicated, "Jus Regiminis," being a juſtification of defenſive arms in general, ſhewing that the revolution was the juſt right of the kingdom. He died at his houſe in Covent Garden, on the 9th of May 1691, and was buried at Hilleſden. His daughter was married to George Nicholas, ſon of ſir Edward Nicholas, ſome time ſecretary of ſtate under the kings Charles I. and II. The titles of his works, which are all on political ſubjects, follow: "Horæ Subſecivæ, or a treatiſe ſhewing the Original, Grounds, Reaſons, and Provocations, neceſſitating our ſanguinary Laws againſt Papiſts, made in the Days of Queen Elizabeth," 1664, 4to. "The Burnt Child dreads the Fire, or an Examination of the Merits of the Papiſts," relating to England, moſtly from their own pens, in juſtification of the late act of parliament, for preventing dangers which may happen, from popiſh recuſants. London, 1675, 4to. "Jus Cæſaris et Eccleſiæ vere dictæ," 1681, fol. To this the author added, on a ſingle ſheet, "An Apology for the Liberty of the Preſs." Wood's Athenæ, Oxon.

DENTON, in *Geography*, a town of America, the chief and poſt town of Caroline county, in Maryland, on the E. ſide of Choptank creek, the E. main branch of Choptank river. It is regularly laid out, has a few houſes, and lies 7 miles S. of Greenſborough, and 37 S. S. E. of Cheſter.

DENTZHEIM, a town of Germany, in the circle of the Lower Rhine, and electorate of Treves; 10 miles N. E. of Treves.

DENUDATION, from *de*, and *nudus*, naked. See EXFOLIATION.

DENUDATION, in *Geology*. This term has lately been introduced, to expreſs thoſe diſappearances of the upper ſtrata of the earth in particular diſtricts, by which the lower ſtrata are partially expoſed to view. The late ingenious Mr. Whitehurſt, after a careful examination of the mineral lime-ſtone diſtrict of Derbyſhire, was led to conclude (pages 155, 156, and 165, of his Enquiry concerning the earth, 1ſt edit.) that the ſtrata of grit and ſhale, now found only in broken and detached maſſes, variouſly diſpoſed over the north part of Derbyſhire, once univerſally prevailed, or were ſuperincumbent upon the lime-ſtone diſtrict. This lime-ſtone diſtrict, whoſe limits, through the county of Derby, Mr. Pilkington has ſince pretty accurately deſcribed, in the map prefixed to his "View of Derbyſhire," extends ſome diſtance into Staffordſhire, and is every where at its edge ſurrounded and covered by ſhale, this ſhale by grit-ſtone, and this grit-ſtone by a coal-ſhale, &c. as the recent obſervations of Mr. Smith and his pupils have ſhewn. It alſo appears, that ſmaller patches of the mineral lime-ſtone are expoſed or denudated at Aſhover, and at Crich in Derbyſhire, ſurrounded and covered by ſhale, which is again covered by grit-ſtone and coal-ſhale, as above-mentioned. On the ſouth ſide of the river Thames, a much larger denudation of the ſtrata has happened, in the counties of Surry, Kent, Suſſex, and Hants, as mentioned in our article COAL, bounded by thoſe tracts of high chalk land, known by the names of the North, and the South-Downs, and their connecting chalk range through Hampſhire; the oppoſite extremity being bounded by the Engliſh channel, or more properly, perhaps, by the oppoſite chalk cliffs on the coaſt of France. This laſt denudated diſtrict, called the Wealds of Kent, Suſſex, and Surry, was examined by Mr. Farey in the autumn of 1806, and a ſection acroſs the Surry and Suſſex Wealds, was prepared.

(See

(See Dr. Dickſon's Agricultural Magazine, vol. ii. p. 30.) The denudated diſtricts of Derbyſhire above-mentioned, were alſo examined by the ſame gentleman, and ſections croſſing two of them, were drawn laſt autumn, preparatory to a mineralogical ſurvey of the whole county, which is now going on. From one of theſe ſections, Mr. White Watſon, the well known mineralogiſt and ſtatuary of Bakewell, has ſince prepared a tablet for the inſpection of the curious, containing all the ſubſtances compoſing the principal ſtrata of Derbyſhire, inlaid in their proper poſitions, ſo as to exhibit a miniature ſection acroſs the county, from Nottinghamſhire to Cheſhire, in paſſing through the towns of Boſſover, Cheſterfield, Bakewell, and Buxton. The inquiries thus making, promiſe to throw a great light upon, if not entirely to explain, the cauſes of the ſtupendous denudations above mentioned, and of others perhaps ſtill larger, which the ſtrata of the Britiſh iſlands exhibit, and of which we ſhall not fail to collect every particular in our power, for the information of our readers on this curious and important ſubject.

Some of the characters by which a denudated tract of country are diſtinguiſhed are the following: 1ſt, the ſame is ſurrounded, in great part, or in whole, by upper ſtrata in the ſeries; 2d, the edges of theſe upper ſtrata have not that indented or fingered form, which is almoſt invariably poſſeſſed by the endings of ſtrata, (ſee that article:) 3d, the edges of the upper ſtrata ſhew evident ſigns of rupture in their abrupt and broken edges, and are often very ſtraight in their direction; 4th, the ſtrata, for ſome diſtance round a denudation, generally riſe or incline towards the ſame; but in ſome rare inſtances, as at Crich (ſee that article), the ſtrata are wholly, or in part, horizontal, or nearly ſo, and the edges of the ſtrata next above the lower or denudated ſtrata may, in that caſe, no where appear on the ſurface, as the ſtrata will all do, in ſucceſſive rings, round the denudation, when they riſe towards it; 5th, the denudated ſtratum, or loweſt one expoſed, frequently forms the higheſt ground of the diſtrict, and riſes generally on all ſides towards a central part, which is much diſlocated and broken by ravines and fiſſures; 6th, the ſucceſſive rings of ſtrata round a denudation, often form diſtinct riſes like ſteps, the top or plane of each of which generally correſponds with ſome parting or looſer ſtratum, where the ſtrata had leſs adherence to each other than in the ſolid maſs of each ſtratum; 7th, denudated diſtricts have ſeldom any rolled pebbles or alluvial matters on them, however thickly they may be diſtributed on the ſtrata which ſurround or form the edges of the denudation: of this the great Suſſex denudation furniſhes a remarkable inſtance; 8th, within denudated diſtricts, it is not uncommon to find patches often of conſiderable extent, having more of the ſuperincumbent ſtrata upon them, than on the parts which ſurround them, and yet the top of the upper of theſe accumulated ſtrata are ſeldom higher than the ſurrounding ground; and, on the other hand, iſolated patches of lower ſtrata are frequently ſeen on the ſurface, ſurrounded by higher ſtrata in the ſeries, and yet theſe inferior denudations ſeldom have their ſurface lower, but often much higher than the ſurrounding ground; of this, Crich-hill abovementioned may be cited as an inſtance; for the great Derbyſhire and Staffordſhire denudation, in the diſappearance of the upper ſtrata, extends much beyond both this place and Aſhover, which alſo is an inferior denudation, within the verge of the great one; and, 9th, all the denudations which have been examined in England, ſeem to be largeſt in extent in a direction nearly approaching to N.W. and S.E. The above obſervations, which have been often repeated with others, perhaps, which are noted in the travelling common-place book of the writer, but were never yet collected out, tend, as he thinks, clearly to ſhew, that denudated diſtricts were, moſt of them, at ſome period, heaved up to a much greater height than at preſent, and that the higher or moſt projecting of theſe lifted parts of the earth were ſcalped or torn away, and no veſtige of them left! That theſe denudations, or ſcalpings of the country, did not take place from volcanic exploſions, or the action of any power from beneath, caſting away the ſuperincumbent ſtrata, will, he thinks, appear evident, becauſe all ſuch cauſes muſt have had the greateſt effect in tearing up the loweſt ſtrata, which moſt confined its action, and ſcattering them in the form of a crater; while the borders of ſuch a diſlocated diſtrict muſt have remained ſtrewed with the diſplaced fragments of ſtrata, as the flanks of volcanic mountains are known to be.

It is preſumed, that the new theory on this ſubject, which Mr. Farey firſt ſhortly promulgated in the Philoſophical Magazine, vol. xxv. p. 45, and vol. xxviii. p. 120. and of which we have ſince given ſome further illuſtrations in our articles COLLIERY, CONTINENT, and others, will ſatisfactorily account for the phenomena of denudation, in ſhewing, that a power once acting from above, on known mechanical principles, was adequate to effects ſtill greater than any which he has examined on the ſurface of the globe, or has contemplated from the writings and deſcriptions of others, ſtupendous as theſe appear to be, and which the all-wiſe Creator has, as in all his other works, brought about by means the moſt ſimple, and who, out of a period of apparent violence and diſorder, which muſt baffle all attempts at deſcription, at length brought about a ſtate of the terraqueous globe, ſo perfectly fitted for the habitation and uſes of the numerous beings, ſince created for its habitation, that the moſt fertile imagination cannot, it is preſumed, ſuggeſt one alteration in the cruſt of the earth, which would really improve the condition of the animate beings who inhabit it. The minute examination of the intereſting diſtrict in and near Derbyſhire, which the gentleman alluded to has undertaken to make, under the liberal patronage of the worthy preſident of the Royal Society of London, will, we truſt, ſoon enable us, by their publication, to enter more fully into his theory, and the application of the ſame to the facts of the Britiſh ſtrata, as the articles referring to them occur in our work.

DENUNCIATION, DENUNCIATIO, a ſolemn publication, or promulgation of any thing.

All veſſels of enemies are lawful prize after denunciation, or proclamation of war.

The deſign of the denunciation of excommunicated perſons is, that the ſentence may be the more fully executed; that the perſons may be known, the entrance into the church refuſed them, and that other people may be warned not to have any communication with them.

DENUTAR, in *Geography*, a town of Egypt on the Nile; 8 miles N.E. of Shabur.

DENYS, JOHN, in *Biography*, doctor in medicine, of Montpelier, where he received his education, is only remembered for the zeal with which he recommended the tranſfuſion of blood for the cure of diſeaſes. Dr. Lower had publiſhed in the Philoſophical Tranſactions for the year 1666, an account of the effects of tranſfuſing the blood of one animal into the veins of another, but Denys was probably the firſt who tried the experiment on the human body, of which he gave an account in the Journal Des Savans for the year 1667. The following year he publiſhed "Lettre Ecrite à M. de Montmor touchant une nouvelle maniere de guerir pluſieurs maladies par la tranſfuſion du ſang," 4to. Paris. In this he tells

us he had reſtored to his reaſon a lunatic, and had cured a M. de Boude, a Swiſs, but his patients unfortunately dying, the parliament prohibited any further experiments being made on human ſubjects

Denys, James, a native of Leyden, rendered himſelf famed as the diſciple, coadjutor, and, at length, the ſucceſſor of M Rau, the lithotomiſt, and not leſs ſo for his ſkill in the art of midwifery, on which ſubject he has left one of the beſt works extant. He was the phyſician and man-midwife to the college for improving the practice of midwifery, which was inſtituted at Leyden in the year 1719. In 1731, he publiſhed "Obſervationes chirurgicæ de calculo renum, veſicæ, urethræ, lithotomia, veſicæ punctura, &c." 8vo. The volume contains many valuable obſervations on the ſigns, by which it may be diſcovered whether there is a ſtone in the bladder, and a deſcription of a great variety of ſtones, differing in their appearance and texture, of which he appears to have made a large collection. The diſeaſe is very common in Holland; in Batavia it is very rare. He cut out a ſtone from the knee of one of his patients, and took from the bladder of a ſubject he diſſected, a large ſtone, having ſeveral branches, which had given the perſon no diſturbance in his life-time. His treatiſe on midwifery, publiſhed in 1733, is written in the Dutch language. It has not been tranſlated, Haller ſays, and is, therefore, leſs known than for its merit it deſerves. Haller Bib. Chir.

Denys, Jacques, a painter of hiſtory and portrait, was born at Antwerp in 1645, and going in his youth to Rome and Venice, ſpent ſome years in copying the works of Raphael, Julio Romano, Guido, and Titian; thus forming his taſte of deſign and colouring from the compoſitions of thoſe celebrated maſters. Having been invited by the archduchеſs of Mantua to her court, he was taken into her ſervice; and not long after he obtained permiſſion to viſit Florence, where he painted the portraits of the duke of Tuſcany and his family: in conſequence of which, he received valuable preſents, and was honoured by the duke with letters patent, expreſſing his eſteem of the artiſt's talents and perſonal merit. On his return to Mantua, he finiſhed ſeveral grand hiſtorical compoſitions for his patroneſs, and adorned the principal apartments of the palace with his excellent performances. Attached to his country, from which he had been abſent in Italy for 14 years, he returned to Antwerp, loaded with riches and honours. His reception was highly honourable; but he ſoon after died, much regretted in every part of Europe, whither his fame had extended. Moſt of his works are in Italy; nevertheleſs, at Antwerp there is to be ſeen an "Ecce Homo" of his painting, which, with regard to deſign and colouring, is altogether in the ſtyle of Vandyck; and in the ſame city there is a portrait, beautifully coloured, and painted with ſingular freedom and force. He was remarkable for correctneſs of deſign, and boldneſs of colouring; and his manner is ſaid to have more of the ſchool of Italy than that of Flanders. Pilkington.

Denys, *St.* in Latin *Fanum Sancti Dionyſii*, or *Sanctus Dionyſius in Francia*, as it was emphatically called, *Saint Denys en France*, in *Geography*, is an ancient town of France, chief place of a diſtrict of the ſame name, in the department of the Seine, with a population of 4425 individuals. Its canton contains 11,510 inhabitants, diſtributed in eleven communes, upon a territorial extent of $51\frac{6}{10}$ kiliometres. The diſtrict counts four cantons, 36 communes, a territorial extent of 208 kiliometres, and 42,984 inhabitants. The ſoil of the diſtrict is uncommonly fertile, and produces all ſorts of corn. The town, which has a ſub-prefect, and ſome calico manufactures, is ſituated on a fine plain on the river Crould, not far from the Seine, ſix miles N. of Paris. Lat. 48° 56′ 8″. But St. Denys is chiefly famous for a celebrated abbey of Benedictines, which was founded here by king Clothar, in the year 600 of our era, and greatly improved by his ſon Dagobert, and by ſeveral ſucceeding French kings. The church is built of the fineſt free-ſtone, in the true Gothic ſtyle, and much admired. It contained a very rich treaſury, and the crown jewels, and was the place of interment for the kings of France, and their families. The firſt king buried here was Dagobert. Among the moſt remarkable monuments in this church, were thoſe of Louis XII. and his queen, Henry II. with his conſort and children, Bertrand du Gueſcelin, conſtable of France, and marſhal Turenne. During the exceſſes of the French revolution, and in particular towards the end of the year 1792, the church of St. Denys was robbed of its treaſure; its tombs were opened, the aſhes of the kings ſcattered in the wind, the bones of thoſe more recently buried were thrown into a hole dug for the purpoſe, the inſcriptions defaced, the monuments overturned, mutilated, carried away, or robbed of every gold and gilt ornament. The building of the temple itſelf was conſiderably damaged; but ſome of the monuments were ſaved from the deſtructive fury of the mob, in a tolerable condition, and preſerved in the muſæum of French monuments at Paris, eſtabliſhed by Mr. Le Noir, in the former church of the Petits Auguſtins, Fauxbourg St. Germain, which is now a national eſtabliſhment. It was at the ſame revolutionary epoch, that the name of St. Denys was changed into that of La Franciade, which the town bore, until Bonaparte placed himſelf at the head of the French government: and ſince this extraordinary man has aſſumed the imperial purple, the church has been repaired, and ornamented with two windows, which are much admired for their uncommonly fine painted glaſs. In the nave, on the right hand, two beautiful expiatory altars have been placed, one for the Merovingian, the other for the Carlovingian race. Between theſe altars is a column deſtined to be adorned with the portraits of the ſix French monarchs, who were at the ſame time emperors. On the left ſide of the nave is an expiatory altar for the third dynaſty of the Capets. In the centre is the principal altar, with marble ſtair-caſes leading to the choirs. The vault, which contained the tombs of the kings, is completely reſtored, and provided with a magnificent gate of gilt braſs. It is deſtined for the princes of the fourth, or Napoleon dynaſty. The eldeſt ſon of Louis Bonaparte, (king of Holland) an infant, has lately been interred in this vault with imperial ſolemnity. There are ſeveral other ſmall towns of the name of St. Denys, in France, as St. Denys in the department of Oude, nine miles ſouth of St. Papoul; St. Denys d'Anjou, in the department of Mayenne, five miles S. W. of Sable; St. Denys de Candé, which is now ſimply called Candé, the chief place of a canton, in the diſtrict of Segré, department of Maine and Loire, with 948 inhabitants, ſix communes, and a population of 6343 individuals for the whole canton, which has an extent of 285 kiliometres; St. Denys de Jargeau, in the department of the Loiret, with a bridge over the Loire, 12 miles S. E. of Orleans; St. Denys de Gaſt, in the department de la Manche, 12 miles S. by E. of Coutances.

Denys, a ſmall river of America, in the ſtate of Maine, and county of Waſhington, 22 miles E. of Machias. Its ſource is in a pond about ſix or eight miles long, and about two miles wide, called Medabemps, in which are the extremities of four townſhips or plantations. After running a ſouth-eaſterly courſe about 15 or 20 miles,

it

it joins the N. branch of Kobbeſkook, and paſſing by Eaſtport on the N. diſcharges itſelf into the Weſt paſſage, between Campo Bello and the Main. In 1794, the country between this river and Machias was a wilderneſs; the banks of this river were at this time thinly ſettled by a regular and well-diſpoſed people.

DENYSVILLE, a poſt town of Waſhington county, in the ſtate of Maine; 27 miles E. of Machias.

DEOBRIGA, in *Ancient Geography*, a municipal town of Spain, in the country of the Autrigons; according to Ptolemy and the Itinerary of Antonine.—Alſo, a town of Spain in Luſitania.

DEOBRIGALA, a town of Spain, in the Tarragoneſe territory.

DEOBSTRUENT Medicines, are thoſe to which are attributed powers of removing obſtructions, which have taken place in any of the veſſels of the body. This general term, according to the older writers on the Materia Medica, includes a variety of medicines of different qualities; thus Alſton obſerves, in different obſtructions, relaxants, reſolvents, attenuants, evacuants, and ſtimulants, are indicated, according to the nature of the obſtructing liquids, whether phlegmatic or inflammatory, acrid, or not acrid, &c. See his Mater. Medica, vol. i. p. 51. But Dr. Cullen has properly baniſhed this as a general term; both becauſe it includes medicines of various powers; and becauſe the theory, upon which the term is founded, is falſe, or at leaſt altogether gratuitous. For there are no juſt grounds for the ſuppoſition, that certain diſorders conſiſt of obſtructions to the circulation, depending upon a matter filling up the veſſels; that the matter is of a certain acrimony, to be corrected by certain medicines; or that any medicines are known capable of penetrating, as ſuch, to the veſſels of any particular viſcus. The only mode in which obſtructions, as they have been called, can be removed, is, by the uſe of local ſtimulants to the veſſels of the part, where that is practicable, or of general ſtrengtheners to the ſyſtem where it is not, or of both combined.

DEODAND, in *Law*, denotes any perſonal chattel, which is the immediate occaſion of the death of any reaſonable creature, and which is forfeited to the king, to be applied to pious uſes, and diſtributed in alms by his high almoner; (1 Hal. P. C. 419. Fleta, l. 1. c. 25. Staunf. P. C. 20, 21.) though formerly deſtined to a more ſuperſtitious purpoſe. In the blind days of popery, it ſeems to have been originally deſigned as an expiation for the ſouls of ſuch as were ſnatched away by ſudden death; and for that purpoſe ought properly to have been given to holy church; in the ſame manner as the apparel of a ſtranger, who was found dead, was applied to purchaſe maſſes for the good of his ſoul: this may account for that rule of law, that no deodand is due, where an infant under the age of diſcretion is killed by a fall *from* a cart, or horſe, or the like, not being in motion, (3 Inſt. 57. 1 Hal. P. C. 422.); whereas if an adult perſon fall from thence and is killed, the thing is certainly forfeited. The true ground of this rule ſeems to be, not as ſir Matthew Hale ſtates it, becauſe an infant is not able to take care of himſelf, but becauſe the child, by its want of diſcretion, was preſumed incapable of actual ſin, and therefore needed no deodand to purchaſe propitiatory maſſes; whereas every adult, who died in actual ſin, ſtood in need of ſuch atonement, according to the humane ſuperſtition of the founders of the Engliſh law. Such is the law, if a perſon be killed by a fall from a thing ſtanding ſtill. But if a horſe, or ox, or other animal, of his own motion, kill as well an infant as an adult, or if a cart run over him, they ſhall in either caſe be forfeited as deodands; which is grounded upon this additional reaſon, that ſuch misfortunes are in part owing to the negligence of the owner, and therefore he is properly puniſhed by ſuch forfeiture. "Omnia quæ movent ad mortem," ſays Bracton (l. 3. c. 5.) "ſunt deo danda," *i. e.* what moves to death is deodand. A ſimilar puniſhment was in like caſes inflicted by the Moſaical law (Exod. xxi. 28.); "if an ox gore a man or a woman, that they die, then the ox ſhall be ſurely ſtoned, and his fleſh ſhall not be eaten; but the owner of the ox ſhall be quit." And among the Athenians (Æſchin. cont. Cteſiphon.) whatever was the cauſe of a man's death, by falling upon him, was exterminated or caſt out of the dominions of the republic. By our ancient law, a well in which a perſon was drowned, was ordered to be filled up, under the inſpection of the coroner. (Flet. l. 1. c. 25. § 10.) Where a thing not in motion is the occaſion of a man's death, that part only which is the immediate cauſe is forfeited; as if a man be climbing up the wheel of a cart, and is killed by falling from it, the wheel alone is a deodand (1 Hal. P. C. 422.); but wherever the thing is in motion, not only that part which immediately gives the wound, (as the wheel, which runs over his body,) but all things which move with it and help to make the wound more dangerous, (as the cart and loading, which increaſe the preſſure of the wheel.) are forfeited. (1 Hawk. P. C. c. 26.) It is of no importance whether the owner were concerned in the killing or not; for if a man kills another with my ſword, the ſword is forfeited as an accurſed thing. And, therefore, in all indictments for homicide, the inſtrument of death and the value are preſented and found by the grand jury, (as that the ſtroke was given by a certain penknife, value ſix-pence) that the king, or his grantee, may claim the deodand: for it is no deodand, unleſs it be preſented as ſuch by a jury of twelve men. (3 Inſt. 57.) No deodands are due for accidents happening upon the high ſeas, that being out of the juriſdiction of the common law; but if a man fall from a boat or ſhip in freſh water, and is drowned, it hath been ſaid, that the veſſel and cargo are in ſtrictneſs of law a deodand. (3 Inſt. 58. 1 Hal. P. C. 423. Molloy de jur. marit. 2. 225.) But juries have of late very frequently taken upon themſelves to mitigate theſe forfeitures, by finding only ſome trifling thing, or part of an entire thing, to have been the occaſion of the death. And in ſuch caſes, although the finding by the jury be hardly warrantable by law, the court of king's bench hath generally refuſed to interfere on behalf of the lord of the franchiſe, to aſſiſt ſo unequitable a claim. (Foſter of homicide, 266.) If a perſon wounded by any accident, as of a cart, horſe, &c. die within a year and a day after, what occaſioned it is deodand; ſo that if a horſe ſtrikes a man, and the owner afterwards ſell the horſe, and the party that was ſtricken die of the ſtroke, the horſe, notwithſtanding the ſale, ſhall be forfeited as deodand, (Plowd. 260. 5 Rep. 110.) The goods and chattels of felo de ſe, &c. were univerſally held to be deodands, and are now forfeitable to the crown. See Felo de se.

Deodands, and forfeitures in general, as well as wrecks, treaſure-trove, royal fiſh, mines, waifs, and eſtrays, may be granted by the king to particular ſubjects, as a royal franchiſe; and, indeed, they are for the moſt part granted out to the lords of manors, or other liberties; to the perverſion of their original deſign. Blackſt. Com. Book i.

DEOGIRE, or Deogur, in *Geography*, a town of Hindooſtan, in the country of Berar; anciently a capital city, and the reſidence of the rajah of Goondwareh, or, as he is called in the Ayin Acbaree, the Goondrajah: 55 miles N. N. W of Nagpour, and 75 N. E. of Ellichpour. N. lat.

the towns of Italy, which threw off the ſovereignty of the empire, and formed themſelves into independant republics. Conrad was now prevailed on to join a cruſade againſt the Saracens, and took the croſs from the hands of Bernard. He accordingly ſet out for Paleſtine, at the head of ſixty thouſand men. Under his banners a troop of females rode in the attitude and armour of men; and the chief of theſe Amazons, from her gilt ſpurs and buſkins, obtained the epithet of the "golden-footed dame." This expedition proved unfortunate: one half of his troops periſhed by ſickneſs, occaſioned, it is believed, through unwholeſome proviſions, furniſhed by the treachery of the Greek emperor, Manuel Comnenus. Conrad, with the remainder, joined Louis VII. king of France, in the ſiege of Damaſcus, exhibiting great proweſs, but without any ſucceſs. The ſiege was raiſed, and the emperor returned to Germany, where he was overwhelmed with public calamity and private affliction, by another revolt of Guelph, and by the death of his eldeſt ſon. This laſt event preyed on his mind, and evidently affected his health. Aware of his approaching end, he was anxious to provide for the ſucceſſion, and recommended his nephew, Frederic Barbaroſſa, to the ſtates of the empire, as a prince of known courage and tried talents. His recommendation was approved, and Conrad died in a ſhort time after, at Bamberg, in the 14th year of his reign. He left one ſon by his empreſs Gertrude, whoſe tender age precluded him from taking any ſhare in the government.

CONRAD IV., the laſt emperor of Germany of this name, was duke of Suabia, and ſon of the emperor Frederick II. He was declared ſucceſſor to his father in 1250, but pope Innocent IV. refuſed to confirm the election. Conrad, notwithſtanding the denunciations of the pontiff, marched into Italy, in order to take poſſeſſion of the kingdom of the two Sicilies, which had been bequeathed to him by his father. He took the city of Naples after an eight months' ſiege: afterwards Capua and Aquino opened their gates to him. He did not long enjoy his ſucceſs: in 1254, he fell ſick, and died in the flower of youth, leaving one ſon, named Conradin, who, at the early age of fourteen, was beheaded by the orders of Charles of Anjou; and in him ended the line of Suabia. Moreri. Univer. Hiſt. Gibbon's Rom. Empire.

CONRAD is a name diſtinguiſhed in literary hiſtory, as well as among the princes of the earth; but as none of that appellation have become very illuſtrious by their works, we ſhall briefly notice them and their writings in a ſingle paragraph. The firſt was a German abbot of the Benedictine order, about the commencement of the tenth century: he wrote "A Continuation of the Hiſtory of France;" and on that account has, by ſome biographical writers, been ſuppoſed a Frenchman; by others, he has been confounded with Conrad of Cologne, who was author of the life of S. Wolphemius. Towards the concluſion of the eleventh century, *Conrad*, biſhop of Utrecht, flouriſhed, to which office he had been raiſed by his pupil, the emperor Henry. He is chiefly known by a work, entitled, "Apologia de Unitate Eccleſiæ conſervanda, et Schiſmate inter Henricum IV. Imp. ac Greg. VIII. Pont. Max." He wrote alſo a ſpirited defence of the imperial right on the ſubject of inveſtitures. The biſhop was aſſaſſinated in his palace, A. D. 1099, by a Frieſland architect, in revenge for having inſtructed him in the method of erecting maſſy buildings on a ſwampy ſoil, and afterwards employing a rival in conſtructing the collegiate church of which the biſhop was founder.—*Conrad* of Sheurn, a German monk, lived in the thirteenth century, and was author of "A Chronicle," and of more than fifty volumes on different ſubjects, chiefly hiſtorical, of which John of Aventine made much uſe in compoſing part of his annals. By his various writings, this monk obtained the honourable epithet of "philoſopher."—*Conrad* of Lichtenau, abbot of Urſberg, in the thirteenth century, was author of "A chronological Hiſtory," extending from Belus, king of Aſſyria, to the year 1449, which was afterwards continued, by an anonymous writer, to the reign of Charles V. It was originally printed at Straſburg, in 1537, and afterwards, with the continuation, in 1569, at Baſil. It created enemies, by ſome reflections on the wars carried on between the German emperors and the popes. The ſame author is ſaid to have written the lives of the ſaints, in 12 books; but they have not come down to us, and probably were never publiſhed.—*Conrad* of Mentz flouriſhed in the thirteenth century, and is known by a work, entitled, "Chronicum Rerum Moguntiarum," from the year 1140 to 1250, which was firſt publiſhed in 1535, and has undergone ſeveral different impreſſions.—About the ſame period lived *Conrad* of Marpurg, who was the firſt perſon of Germany that received the infamous commiſſion of inquiſitor from the papal ſee; an office which he executed with ſo much cruelty, that at length he fell a ſacrifice to the indignation of popular clamour. He wrote "The Life of the Princeſs Elizabeth of Thuringia," who has obtained a place among the ſaints.—*Conrad* is the name of two Dominican monks, natives of Saxony, in the fourteenth century. One was a member of the chapter of his order in that province, and the other appointed by the pope vicar-general of Saxony, in the year 1350. The former publiſhed, among many other things, "A Commentary on the Book of Job;" "A Concordance to the Bible;" "The Student's Dream;" and "A common-place Book for the Uſe of Preachers."—*Conrad* of Aſti, a Piedmonteſe Dominican monk, was author of "Commentaria in Jus Canonicum," and other pieces. He died in the year 1470.—In the ſixteenth century appeared *Conrad Leontinus*, a learned German Ciſtertian monk, who appears to have been well acquainted with the beſt writers in profane and ſacred literature, and to have maintained an intimate correſpondence with the moſt learned men of his time. He publiſhed, in the year 1507, at Baſil, "Nicholas de Lyra's Commentary on the Bible, with marginal Notes."—There were ſeveral others of this name, but it is needleſs to mention them all. *Conrad* of Mur, canon of the church of Zurich, lived in the thirteenth century, and is known for his treatiſe on the ſacraments, and the lives of the popes: and *Conrad* of Saxony wrote "A Chronicle," and ſome hiſtorical works, to which no date is aſſigned. Moreri.

CONRI, FLORENCE, a Franciſcan friar, was born in the province of Connaught, about the year 1560, and was ſent at an early age into Spain, as a ſtudent in theology and the philoſophy of the times. When he had finiſhed his ſtudies, he travelled into the Low Countries, where he acquired great reputation among the Catholics, by his aſſiduity and zeal in illuſtrating and defending the doctrines of St. Auguſtine. He was author of ſeveral tracts on theological ſubjects, among which were "The Mirror of the Chriſtian Life;" an "Iriſh Catechiſm," printed at Louvain, in 1626; and "Tractatus de Statu parvulorum ſine Baptiſmo decedentium ex hac Vita," Lovanii, 1624. As a politician, he was fixed on to conciliate his countrymen to the meaſures of the court of Spain, when Philip III. attempted the conqueſt of Ireland, during the reign of Elizabeth. On the failure of that enterprize he eſcaped from

mappes, Lys, Eſcaut or Scheldt, Deux-Nethes, Meuſe Inferieure, Ourthe, and Dyle. 2. The northern region contains 11 departments, *viz.* Pas de Calais, Du Nord, Aiſne, Seine and Marne, Seine, Seine and Oiſe, Eure and Loire, Eure, Seine Inferieur, Somme, and Oiſe. 3. The north-eaſt region includes 10 departments, *viz.* Ardennes, Meuſe, Moſelle, Bas-Rhin, Haut-Rhin, Voſges, Haute-Marne, Aube, Marne, and Meurthe. 4. The eaſtern region comprehends 11 departments, *viz.* Cote d'Or, Haute-Saone, Doubs, Leman, Mont-Blanc, Iſere, Loire, Saone and Loire, Jura, Ain, and Rhone. 5. The ſouth-eaſt region contains 12 departments, *viz.* Haute-Loire, Ardeche, Drome, Hautes-Alpes, Baſſes-Alpes, Alpes-Maritimes, Var, Bouches du Rhine, Gard, Vaucluſe; and the two departments of the iſland of Corſica, *i. e.* Golo and Liamone; the Elbe and its dependencies, Capraia, Pianoſa, Palmajola, and Monte Chriſto, united to the French territories in 1802, form a diſtinct department. 6. The ſouthern region comprehends 9 departments, *viz.* Correze, Cantal, Lozere, Herault, Pyrenées Orientales, Aude, Tarn, Lot, and Aveiron. 7. The ſouth-weſt, or Garonne, region includes 9 departments, *viz.* Gironde, Dordogne, Lot and Garonne, Haute-Garonne, Ariege, Hautes-Pyrenées, Baſſes-Pyrenées, Les Landes, and Gers. 8. The weſtern region contains 9 departments, *viz.* Loire Inferieure, Mayenne and Loire, Indre and Loire, Vienne, Haute-Vienne, Charente, Charente-Inferieure, Vendée, and Deux-Sévres. 9. The north-weſt region comprehends 9 departments, *viz.* Manche, Calvados, Orne, Sarthe, Mayenne, Morbihan, Finiſterre, Cotes du Nord, and Ille and Vilaine. 10. The central region includes 9 departments, *viz.* Loir and Cher, Loiret, Yonne, Nievre, Allier, Puy de Dome, Creuſe, Indre, and Cher. Piedmont, united to the French republic in 1802, includes the 6 following departments, *viz.* Doire, Seſia, Marengo, Tanaro, Stura, and Po. See a more particular account of each department under its appropriate article.

An alphabetical Liſt of Departments, ſpecifying their Relations to the Provinces into which France was formerly divided, together with their Extent, Subdiviſions, and Population, according to M. Haſſenfratz, &c.

DEPARTMENT, in *Juriſprudence*, ſignifies diſtribution, diviſion, or allotment of certain employments among ſeveral perſons. Thus the great officers of ſtate, &c. have each their ſeveral departments: and the buſineſs of the ſecretaries of ſtate in particular, is generally divided into two partitions; the one officiating for the ſouthern, the other for the northern department: though ſometimes another is added on particular occaſions.

DEPARTURE, or DEPARTER, in *Law*, a term properly applied to a perſon, who firſt pleading one thing in bar of an action, and that being replied to, waves it, and inſiſts on ſomething different from his firſt plea.

Or, it may be applied to a plaintiff, who, in his replication, ſhews a new matter different from that in his declaration. (Plowd. 7, 8. 2 Inſt. 147.) So if a man plead a general agreement in bar, and in his rejoinder allege a ſpecial one, it ſhall be adjudged a departure in pleading. The defendant hereupon demurreth, becauſe it was a departure from the declaration.

This departure in pleading, if it were allowed, might occaſion endleſs altercation. Therefore the replication muſt ſupport the declaration, and the rejoinder muſt ſupport the plea, without departing out of it, as in the caſe of pleading no award made, in conſequence of a bond of arbitration, to which the plaintiff replies, ſetting forth an actual award: now the defendant cannot rejoin that he hath performed this award; for ſuch rejoinder would be an entire departure from his original plea, which alleged, that no ſuch award was made; therefore he hath now no other choice but to traverſe the fact of the replication, or alſo to demur upon the law of it.

DEPARTURE *in deſpite of the court*, is when the tenant, or defendant, after appearing to the action brought againſt him, and having a day over in the ſame term, does not appear at the day, but makes a *default*. This is a *departure in deſpite of the court*; and therefore he ſhall be condemned. See DEFAULT.

The departure is always on the part of the tenant, or defendant; and its entry is, *Quod prædictus A, licet ſolemniter exactus, non revenit, ſed in contemptum curiæ receſſit.*

DEPARTURE, in *Navigation*, is the eaſting or weſting of a ſhip, with reſpect to the meridian from which it departed or ſailed. Or, it is the difference of longitude, either eaſt or weſt, between the preſent meridian the ſhip is under, and that where the laſt reckoning or obſervation was made. This departure, any where but under the equator, muſt be accounted according to the number of miles in a degree proper to the parallel the ſhip is under. See SAILING.

DEPESTA, in *Antiquity*, a wine veſſel which the Sabines, on any feſtival day, ſet on the table of their gods.

DEPHLEGMATION, in *Chemiſtry*. This term is applied to the abſtraction of the phlegm, or merely watery part of any ſubſtance, and may be performed in ſeveral ways. Thus, ſpirit of wine is dephlegmated by diſtillation, and the *phlegm* remains in the alembic. Sulphuric acid, on the other hand, is dephlegmated by boiling, and the phlegm riſes firſt, and is diſſipated in vapour.

DEPHLOGISTICATED AIR. See OXYGEN.

DEPHLOGISTICATED *Nitrous Air*. See NITROUS OXYD.

DEPHLOGISTICATED *Nitrous Acid*. See NITROUS *Acid*.

DEPILATORY, in *Medicine*, a plaiſter, or medicine, applied on any hairy place, in order to bring off the hair. The word is formed of the particle *de*, and *pilus*, *hair*.

Depilatories are principally compoſed of lime and orpiment, which is very cauſtic, and even a dangerous mineral.

DEPIZNANO, in *Geography*, a town of Naples, in the province of Calabria Citra; three miles S. S. W. of Coſenza.

DEPLOY, in *Military Tactics*, means the expanſion of a body of troops, previouſly compacted in column, &c. ſo as to offer a larger front; generally for the purpoſe of performing ſome evolution, or of arranging a line, or of directing an attack, in ſome direction leaſt expected by the enemy. This deception is moſtly carried into eff-ct by allowing the front to keep its poſition, or to continue advancing, while the rear diviſions open abruptly, (or, if the ſituation demands, gradually,) ſo that the enemy remain in a ſtate of incertitude as to the extent and direction of the evolution, until it has been nearly completed, and its intention has been partly effected.

Where an army moves in ſeveral columns, it is often expedient to cauſe their ſeveral ſub-diviſions to deploy, ſo as to bring the whole into line, either to the front, or to the flank. In performing this evolution, fixed points muſt be aſcertained to direct the march of the ſeveral ſub-diviſions; ſo that they may all proceed directly to their reſpective ſtations, without making any circuitous movements.

The term "deploy" is derived from the French word *deployer*, which ſignifies to unfold, to open, to expand, or to diſcloſe. The military reader will perceive, that the term is extremely appropriate to the change which takes place from the column to the formation in line.

DEPONENT, DEPONENS, in the Latin *Grammar*, a term applied to verbs which have active ſignifications, but paſſive terminations, or conjugations, and want one of their participles paſſive.

Such is *minor*, *I threaten*, which has for participles *minans*, *minaturus*, and *minatus*, but no *minandus*, which ſhould be the participle paſſive.

They are called *deponents*, as having depoſited, or laid aſide their paſſive ſignification.

DEPONENT, in a legal ſenſe, a perſon who makes a *depoſition* or *affidavit*, which ſee.

DEPOPULATION, the act of waſting, deſtroying, deſolating, or unpeopling a place. Coke, Inſtit. part. iii. fol. 204.

DEPOPULATORES AGRORUM, in our *Statutes*, ſuch as depopulate or diſpeople lands.

It appears by the ſtatute 4 Hen. IV. c. 2. that theſe were great offenders by the ancient law, and that the appeal or indictment againſt them ought not to be in a general, but in a ſpecial manner. They got their name of *depopulatores agrorum*, becauſe by proſtrating or decaying the houſes and habitations of the king's people, they depopulate towns. Coke, 3 Inſt. fol. 204.

DEPORTATION, from *deporto*, *I carry away*, a ſort of baniſhment in uſe among the Romans, whereby ſome iſland, or other place, was allotted to a criminal for the place of his abode, with a prohibition from ſtirring out of the ſame upon pain of death.

Ulpian makes this difference between *deportation* and *relegation*; that the former confined the party to one certain place for ever; whereas relegation was frequently revoked, and allowed the exile a little more liberty.

By *deportation* a perſon loſt the rights of a Roman citizen.

DEPOSIT, DEPOSITUM, a thing put into the hands of another, to be kept gratis.

The civilians divide *depoſitum* into *ſimple* and *judiciary*.

DEPOSIT, *Judiciary*, is that whoſe property is conteſted between ſeveral perſons, and depoſited in the hands of ſome third perſon, by decree of a judge.

DEPOSIT, *Simple*, is either voluntary, or neceſſary. Neceſſary is that done in caſe of hoſtility, ſhipwreck, fire, &c.

Innholders are reſponſible for the baggage brought to them. as being a *neceſſary depoſit*.

DEPOSITARY, in the French law, a perſon entruſted as keeper or guardian of any thing.

Ordinary depoſitaries are not to warrant the thing left with them, in caſe it be loſt or ſtolen. They are only to anſwer for a fraud, or breach of faith; not for negligence. But a *neceſſary depoſitary*, as an innkeeper, is accountable for a theft or robbery, if there have been any negligence in the caſe: and by the Engliſh law, even whether there were any negligence or not.

DEPOSITIO, in *Grammar*, is a name which the Latins gave to the final cadence, which terminates, as it were, the meaſure of the verſe. The Greeks called it αποθεσιν, and καλαλεξιν. Hence ariſeth the diſtinction of verſe into four ſpecies, viz. *acatalectic*, *catalectic*, *brachycatalectic*, *and hypercatalectic*.

DEPOSITION, DEPOSITIO, among the *Ancients*, a ceremony obſerved immediately upon a perſon's expiring, and was a ſolemn manner of laying the corpſe upon the ground. See BURIAL.

DEPOSITION, in *Geology*. The phenomena of the ſtratification obſervable in the cruſt of the earth, can leave no manner of doubt, that the ſame was formed by matters depoſited or precipitated from a fluid, in which the whole was once immerſed; on this point almoſt all writers are now agreed, and their principal differences of opinion ariſe on the manner of this depoſition, that is, whether the ſame was mechanical, and the matters depoſited, only the ruins or detritus of former mountains or ſtrata, or precipitations in conſequence of recent chemical unions in the ſuperincumbent fluid; or, whether both of theſe cauſes have not operated, and perhaps at the ſame period of time. It may fairly perhaps be obſerved, that the exiſtence of the primeval mountains, whoſe diſintegration is ſuppoſed above in many caſes, never has been and never can be proved, and that the phenomena of the endings of the ſtrata are altogether irreconcileable with mechanical depoſition, the Britiſh ſtrata being found to fall ſhort of each other in extent weſtward, as the ſeries is aſcended, and none of the matter peculiar to any ore ſtratum is found depoſited upon the endings of the inferior ſtrata: the chalk ſtrata for inſtance, and in a certain determinate line, paſſing through or near to Wantage, Watlington, Prince-Riſborough, Wendover, Tring, Ivinghoe, Dunſtable, Hitchin, Baldock, Royſton, &c. and beyond this line to the north-weſtward, no beds of chalk are found (in Britain at leaſt,) covering the vaſt ſucceſſion of ſtrata, whoſe ſituations are lower in the ſeries, and whoſe lines of endings are conſequently farther to the weſtward, although the alluvial or rounded fragments of chalk and its attendant extraneous foſſils, are plentifully diſtributed on the ſurface in certain directions, for a great diſtance from the endings of the chalk ſtrata, indicate the exiſtence of vaſt tides or inundations, proceeding from the S.E. towards the N.W. over even the higheſt hills, at a period ſubſequent to the depoſition and hardening of the ſtrata. (See SATELLITIC *Tides*.) That chemical affinities acted, both in the formation of the ſeveral ſubſtances themſelves in the univerſal fluid or ocean, and alſo in this depoſition upon the plane of the ſtratum laſt depoſited, in preference to any other part of the bottom of the fluid, ſeems very evident, and it ſeems alſo, that theſe affinities have been further active in ſome particular ſtrata, in forming vaſt accumulations of particular matters, within the limits of the ſtrata in which they are imbedded, and with which they are coeval: that curious aſſemblage of ſtrata, called, in our article COAL, the "red earth" for inſtance, has in ſome inſtances vaſt concretions or accumulations of rock-ſalt in it, as at the Wyches in Cheſhire and Worceſterſhire; in other inſtances gypſum is imbedded therein, as in various parts of Nottinghamſhire, Derbyſhire, &c.; and the recent obſervations of Mr. Farey, a pupil of Mr. Smith's, ſeem to render it more than probable, that the vaſt accumulation or cryſtals of ſienite and ſlate, which abound in Charnwood Foreſt in Leiceſterſhire, are concretions in theſe ſame ſtrata of red earth, as thoſe of the Malvern hills and other places alſo probably are. See STRATA.

DEPOSITION, in *Law*, a teſtimony given in court by a witneſs upon oath.

In chancery, depoſition is a teſtimony ſet down in writing, by way of anſwer to the interrogatories exhibited in chancery, where ſuch witneſs is called *deponent*.

For the purpoſe of the examination of witneſſes, interrogatories are framed, or queſtions in writing; which, and which only, are to be propoſed to the witneſſes in the cauſe. Theſe interrogatories muſt be ſhort and pertinent; not leading ones; (as, "did you not ſee this," or, "did you not hear that?") for if they be ſuch, the depoſitions taken upon them will be ſuppreſſed, and not ſuffered to be read. For the examination of witneſſes in or near London, there is an "Examiner's Office" appointed; but for ſuch as live in the country, a commiſſion (ſee COMMISSION) to examine witneſſes is uſually granted to four commiſſioners, two named of each ſide, or any three or two of them, to take the depoſitions there. And if the witneſſes reſide beyond ſea, a commiſſion may be had to examine them there upon their own oaths, and (if foreigners) upon the oaths of ſkilful interpreters. And it hath been eſtabliſhed (Atk. 21.) that the depoſition of an heathen, who believes in the Supreme Being, taken by commiſſion in the moſt ſolemn manner, according to the cuſtom of his own country, may be read in evidence. The commiſſioners are ſworn to take the examinations truly and without partiality, and not to divulge them, till publiſhed in the court of chancery; and their clerks are alſo ſworn to ſecrecy. The witneſſes are compellable by proceſs of ſubpœna, as in the courts of common law, to appear and ſubmit to examination. When their depoſitions are taken, they are tranſmitted to the court with the ſame care that the anſwer of a defendant is ſent. When all the witneſſes are examined, then, and not before, the depoſitions may be publiſhed; by a rule to paſs publication; after which they are open for the inſpection of all parties, and copies may be taken of them. After a witneſs is fully examined, the examinations are read over to him, and the witneſs is at liberty to alter, or annul any thing, after which he ſigns them, and then, but not before, the examinations are complete, and are deemed good evidence. (1 P. Wms. 415.) The ſame practice prevails in the commons, in eccleſiaſtical cauſes.

Depoſitions in the chancery, after a cauſe is determined, may be given in evidence in a trial at bar in B. R. in a ſuit for the ſame matter, between the ſame parties, if the party that depoſed be dead; but if he be living, he muſt appear in perſon in court to be examined. (1 Lil. Abr. 445.)

Depoſitions of informers, &c. taken upon oath before a coroner, upon an inquiſition of death; or before juſtices of peace on a commitment or bailment of felony, may be given in evidence at a trial for the ſame felony; if

if it be proved on oath that the informer is dead, or unable to travel, or kept away by the procurement of the priſoner; and oath muſt be made, that the depoſitions are the ſame that were ſworn before the coroner or juſtice, without any alteration. (2 Hawk. P. C.) Depoſitions taken before a coroner cannot be given in evidence upon an appeal for the ſame death; becauſe this is a different proſecution from that in which they were taken:—and it has been adjudged, that the evidence given by a witneſs at one trial, could not, in the ordinary courſe of juſtice, be made uſe of againſt a criminal, on the death of ſuch witneſs, at another trial. (2 H. P. C.) The depoſitions of witneſſes abroad, and of ſuch are aged or going abroad *de bene eſſe*, to be read in evidence, if the trial could be deferred till after their death or departure, are now frequently effected by mutual conſent in trials at common law, if the parties are open and candid; and this may be done indirectly at any time, through the channel of a court of equity. When the cauſe of action ariſes in India, and a ſuit is brought upon it in any of the courts of Weſtminſter, the court may iſſue a commiſſion to examine witneſſes upon the ſpot, and tranſmit the depoſitions to England. Stat. 13 Geo. III. c. 63.

Deposition is alſo uſed for the ſequeſtering, or depriving a perſon of his dignity and office.

This depoſition only differs from abdication, in that the latter is ſuppoſed voluntary, and the act of the dignitary, or officer himſelf; and the former of compulſion, being the act of a ſuperior power, whoſe authority extends thereto. Accordingly, ſome ſay the depoſition, and ſome the abdication of king James II.

Depoſition does not differ from deprivation: we ſay indifferently, a depoſed, or deprived biſhop, official, &c. See Deprivation.

Depoſition differs from ſuſpenſion, in that it abſolutely and for ever ſtrips or diveſts a prieſt, &c. of all dignity, office, &c. whereas ſuſpenſion only prohibits, or reſtrains, the exerciſe thereof.

Depoſition only differs from degradation, in that the latter is more formal, and attended with more circumſtances, than the former; but in effect and ſubſtance they are the ſame; thoſe additional circumſtances being only matter of ſhow, firſt ſet on foot out of zeal and indignation, and kept up by cuſtom, but not warranted by the laws or canons. See Degradation.

DEPOT. This term, when applied to military matters, ſignifies a depoſit, or reſerve for ſtores, proviſions, &c. alſo a ſtation for the reception, and training of recruits. The difficulty of removing large quantities of ammunition, &c. on emergency, added to the great diſtreſs occaſioned to armies, whether victorious or defeated, by the removal of depots from the vicinity of their *points d'apui*, (which are generally towns ſtrongly fortified, or *corps de reſerve* poſted in the moſt advantageous manner,) ſhews the abſolute neceſſity for rendering depots ſufficiently ſtrong to maintain themſelves for ſome weeks at leaſt, againſt even a very powerful force. The immenſe importance attached to the ſupplies of whatever an army may, from time to time, ſtand in need of, has been long underſtood on the continent, where every ſtrong hold is a depot, furniſhed according to its ſituation, extent, and ſtrength, with all thoſe articles indiſpenſible to an army taking the field. Some of theſe are capable of maintaining a garriſon of 30,000 men for a whole year; beſides providing arms, ammunition, and camp equipage, for an army of double that number. The great arſenal at Ulm was of this claſs, but was nearly exhaulted at the time of its ſurrender, when general Mack ſo iguominouſly loſt the flower of the Auſtrian army.

A depot ſhould be built in a peculiar manner: that is, it ſhould contain an immenſe pile of bomb-proof buildings, of which the loweſt tier ſhould be reſerved for the preſervation of proviſions requiring to be kept cool; this ought to be below the ſurface of the area; the ground-floor ſhould be allotted to artillery, and ordnance ſtores, the walls and piers being furniſhed with ſtrong wooden battens, (projecting a little to obviate the danger of damp,) for the ſupport of muſquets, carabines, piſtols, ſwords, halberts, bayonets, pikes, and every deſcription of ſmall arms. The ſecond floor ſhould be devoted to the receipt of camp equipage, and the upper to the lodgment of ready filled cartridges. The great magazines for powder ſhould be ſeparate: the whole of the principal, or body of the place, ſhould be caſemated for the accommodation of troops, and pierced (though perhaps maſked) for the reception of heavy cannon. The whole of the outworks ſhould be of the beſt materials, and on the moſt compact ſyſtem of defence.

Ten ſuch depots, advantageouſly ſituated, each capable of ſupplying ſtores, &c. to an army of 50 or 60,000 men; and demanding not more than 5000 for their defence, reſpectively, would give a moſt deſireable acceſſion of ſtrength to our national defence; and, in the moment of doubtful conteſt, inſpire our armies with confidence. At preſent we do not perceive, throughout the kingdom, any depot capable of affording ſuch ſupplies, or of reſiſting even a moderate force, for ſuch a time as might either enable a diſcomfited corps to rally, or diſtant ones to afford them relief.

DEPRECATION, from *deprecor, I intreat*, in *Rhetoric*, a figure whereby the orator invokes the aid or aſſiſtance of ſome one; or prays for ſome great evil or puniſhment to befall him who ſpeaks falſely, either himſelf or his adverſary.

DEPRECATORY, or Deprecative, in *Theology*, a term applied to the manner of performing ſome ceremonies in the form of prayer.

Among the Greeks, the form of abſolution is deprecatory; being conceived in theſe terms, *May God abſolve you!* whereas in the Latin, and even in ſome of the reformed churches, it is in the declarative form, *I abſolve you.*

DEPRESSED Leaf, in *Botany*. See Leaf.

DEPRESSION *of Equations*, in *Algebra*. See *Equation*.

Depression *of the Pole*, in *Aſtronomy*. So many degrees as you ſail, or travel from the pole towards the equator, ſo many you are ſaid to depreſs the pole, becauſe it becomes reſpectively ſo much lower or nearer to the horizon.

Depression. If the zenith diſtance of an object exceeds 90°, its exceſs above that quantity, or its angular diſtance from the horizon, is called the depreſſion.

In nautical obſervations it is neceſſary to know the depreſſion or dip of the ſea, to correct the apparent altitude of an obſerved object.

In trigonometrical ſurveys it is by means of the obſerved depreſſion that the height of one ſtation above the level of the other is computed, and likewiſe the quantity of the terreſtrial refraction.

The method of calculating theſe depreſſions is founded on this theorem. The ſum of the depreſſions of two objects, as ſeen reciprocally from each other, is equal to the arc they intercept on the ſurface of the earth.

Let A, B (*Pl.* IX. *Aſtronomy, fig.* 61.) be two ſtations unequally diſtant from the centre of the earth C; A′ B A, B′ A B their depreſſions below their reſpective horizons, it is evident, that ſince both the ∠ C and the ſum of the angles A′ B A and B′ A B are complements of the angle C to two right angles, the angle C = ∠ A′ B A + ∠ B′ A B.

The

The following method is given by Delambre for finding the quantity of terreſtrial refraction.

Let C be the centre of the earth (*Pl.* IX. *Aſtronomy, fig.* 62.), A and B two ſignals. If from the point A, we obſerve the point B, it will appear at B′, by the effect of the refraction; the point A will, when ſeen from B, for the ſame reaſon appear at A′.

Let the apparent zenith diſtances

$$Z\,A\,B' = \delta \text{ and } V\,B\,A' = \delta'$$

and the angles of refraction,

$$B\,A\,B' = r \quad A\,B\,A' = r'$$

The true zenith diſtances will be

$$Z\,A\,B = \delta + r = D$$
$$V\,B\,A = \delta' + r' = D'.$$

Therefore $Z\,A\,B + V\,B\,A = \delta + \delta' + r + r'$. (1)

And becauſe the ſum of the exterior angles of a triangle is equal to the two interior and oppoſite

$$\angle Z\,A\,B = C + A\,B\,C$$
$$\angle V\,A\,B = C + B\,A\,C,$$

and $Z\,A\,B + V\,B\,A = 180° + C = D + D'$. (2)

and $\delta + \delta' + r + r' = 180° + C$;

ſince r is nearly equal r'

$$r = \frac{C}{2} - \tfrac{1}{2}(\delta + \delta' - 180). \quad (3)$$

$$\frac{r}{C} = \frac{\frac{1}{2}C - \frac{1}{2}(\delta + \delta' - 180)}{C} = n. \quad (4)$$

and $r = n\,C$.

The quantity n varies extremely, according to the ſtate of the atmoſphere. In the trigonometrical ſurvey it was found to vary from $\frac{1}{4}$ to $\frac{1}{20}$.

The mean may be taken $\frac{1}{12}$ or $n = 0.08$. From the above equations we obtain

$$\angle Z\,A\,B = \delta + r = 90° + \tfrac{1}{2}C + \tfrac{1}{2}(\delta - \delta').$$
$$\angle V\,B\,A = \delta' + r' = 90° + \tfrac{1}{2}C + \tfrac{1}{2}(\delta - \delta').$$

Example.

Let δ be equal to 90° 15′ 30″.

δ' 89 57 50.

K the diſtance between the two ſignals = 93.522 feet.

Firſt find ∠ C - -	Log. K	= 4.97091
	R	= 5.31442
Co-log. ϱ the mean radius of the earth	ϱ	= 2.68000
	923″.8	= 2.96533

Angle C - = 15′ 23″.8

$\delta = 90° 15' 30''$

$\delta' = 89\ 57\ 50$

$\delta + \delta' - 180 = 0\ 13\ 20$

$\frac{\delta + \delta' - 180}{2} = 0\ 6\ 40$

$\frac{C}{2} = 7\ 42$

$r = nC =$ 1′ 2″

Log. r (62″)	= 1.79239
Co-log. C	= 7.03466
$n = 0.067$	= 8.82705

To find the difference in the heights of two ſtations above the level of the ſea, by obſerving their depreſſions.

Let C be the centre of the earth conſidered as a ſphere, A, B, two points unequally diſtant from the centre. If A B′ is a true level line or terreſtrial arc, B B′ = H will be the difference of the level of the two points A and B. If, moreover, $Z\,A\,B = D = \delta + r$ be the true zenith diſtance of the point B, then, ſince $B'\,A\,C = 90° - \frac{1}{2}C$.

$B\,A\,B' = 180° - Z\,A\,B - B'\,A\,C = 180° - D - 90° + \frac{1}{2}C = 90° - D + \frac{1}{2}C$.

$A\,B\,B' = A\,B'\,C - B\,A\,B' = 90° - \frac{1}{2}C - 90° + D - \frac{1}{2}C = D - C$.

In the triangle B A B′ making A B′ = K.

$$H = \frac{K \text{ ſin. } A}{\text{ſin. } B} = \frac{K \text{ ſin. } (90° + \frac{1}{2}C - D)}{\text{ſin. } (D - C)} = \frac{K \text{ coſ. } (\frac{1}{2}C - D)}{\text{ſin. } (D - C)}. \quad (1.)$$

If we ſuppoſe the angle B′ a right angle, then we ſhall have very nearly

$$H = K \cot. (\delta + r - \tfrac{1}{2}C). \quad (2.)$$

Relatively likewiſe to the level of the point A.

$$H = -K \cot. (\delta' + r - \tfrac{1}{2}C).$$

If we employ the expreſſion $H = K \cot. (\delta' + r - \frac{1}{2}C)$ it will be relatively to the point B.

It has been demonſtrated above, that

$$Z\,A\,B = 90° + \tfrac{1}{2}C + \tfrac{1}{2}(\delta - \delta')$$
$$V\,B\,A = 90° + \tfrac{1}{2}C - \tfrac{1}{2}(\delta - \delta)$$

therefore, $B\,A\,C = 180 - Z\,A\,B = 90° - \frac{1}{2}C + \frac{1}{2}(\delta - \delta')$

$$B'\,A\,C = 90° - \tfrac{1}{2}C.$$
$$B\,A\,B' = B\,A\,C - B'\,A\,C = \tfrac{1}{2}(\delta' - \delta)$$
$$B'\,B\,A = 180° - V\,B\,A = 90° - \tfrac{1}{2}C - \tfrac{1}{2}(\delta - \delta')$$

and $H = \frac{K \text{ ſin. } B\,A\,B'}{\text{ſin. } A\,B\,B'} = \frac{K \text{ ſin. } \frac{1}{2}(\delta' - \delta)}{\text{coſ. } \frac{1}{2}(\delta' - \delta + C)}$. (4.)

This formula is exact, but we may often take $\frac{1}{2}C = 0$, then, ſince $\frac{\text{ſin.}}{\text{coſ.}} = \text{tang.}$

$$H = K \text{ tang. } \tfrac{1}{2}(\delta' - \delta). \quad (5.)$$

Hence, we may obtain the height of a ſtation above the level of the ſea, by obſerving, when it is viſible, the horizon of the ſea. For let A B be a tangent from the obſerver at B to the ſea at A. Let C A = ϱ, B B′ = N.

Then, in the triangle C A B,

$$C\,B = \frac{\varrho}{\text{ſin. } (90° - C)} = \frac{\varrho}{\text{coſ. } C}.$$

$$B\,B' = N = \varrho \left(\frac{1 - \text{coſ. } C}{\text{coſ. } C}\right);$$

but 1 − coſ. C = ſin. C tang. $\frac{1}{2}$ C,

therefore, N = ϱ tang. C tang. $\frac{1}{2}$ C:

Alſo, $C = 90° - B = 90° - (180 - D) = D - 90°$, and $D = \delta + r$. Therefore, N = ϱ tang. $(\delta + r - 90°)$ tang. $\frac{1}{2}(\delta + \varrho - 90°)$. When r is unknown, it may be deduced from the equation $r = n\,C$.

But in practice it will be more convenient to transform N into ſome function of n, which may be effected thus.

$C = \delta - 90°$; neglecting the refraction, which may be done without ſenſible error, then $r = nC = n(\delta - 90°)$; ſubſtituting this laſt value in equation, (6.) and recollecting that tang. $m\,r = m$ tang. x, when x is very ſmall, and m does not much exceed unity, we ſhall have

$$N = \tfrac{1}{2}\varrho \text{ tang.}^2 (\delta - 90° + n)(\delta - 90°) = \tfrac{1}{2}\varrho \text{ tang.}^2 \big((1+n)(\delta - 90°)\big)$$

and very nearly

$$N = \tfrac{1}{2}\varrho\,(1 + n) \text{ tang.}^2 (\delta - 90°). \quad (7.)$$

Example I.

At the ſtation A, the zenith diſtance of the point B was obſerved 90° 15′ 30″; and at the ſtation B, the zenith diſtance of A was obſerved 89° 57′ 50″, the diſtance from A to B 93,522 feet; required the height of A above the level of B.

1ſt. By the exact formula $H = \frac{K \text{ ſin. } \frac{1}{2}(\delta' - \delta)}{\text{coſ. } \frac{1}{2}(\delta' - \delta + C)}$.

$\delta' =$

$\delta' = 89° 57' 50''$
$\delta = 90\ 15\ 30$
$\delta' - \delta = -\ 17\ 40$
$C = +\ 15\ 24$
$\delta' - \delta + C = -\ 2\ 16 = p.$

Log. fin. $\frac{1}{2}\delta' - \delta' = -\ 7.40985$
Log. K $= +\ 4.97091$
Cof. $\frac{1}{2}p$ $\quad 0.00000$
$-\ 240.3 = \quad 2.38076$

Therefore, B is 240.3 feet below the level of A.

Example II. *by formula* (5.).

Log. K $= 4.97091$
Tang. $\frac{\delta' - \delta}{2} = 7.40985$

$2.38076 = 240.3$ feet as above.

Example III.

When only δ is given. Equation (2.)

Let $n = 0.067$,
$H = K \cot.(\delta + 0.67\ C - 0.5\ C)$,
$= K \cot.(\delta + .433\ C)$
$\delta = 90° 15' 30''$
$-\ 433\ C = \quad 6\ 40$
$\quad 8\ 50$

Log. tang. $8' 50'' = 7.40985$
4.97091
$2.38076 = 240.3$ feet.

Example IV.

To find the height of a ſtation, by obſerving the depreſſion of the horizon of the ſea.

Let the obſerved depreſſion be $15' 25''$, required the height of the obſerver above the level of the ſea.

$N = \frac{1}{2}\varrho\ (1 + n)^2 \text{ tang.}^2 (\delta - 90°)$.

Log. 0.5 $= 9.69897$
Log. ϱ $= 7.32000$
Log. $(1.08)^2$ $= 0.06685$ } 7.08582.
Log. tang.^{2} $15' 25''$ $= 5.30344$
$2.38926 = 245$ feet.

The three firſt terms being conſtant, we have the following rule.

To the conſtant log. 7.08582 add twice the log. of the tangent of the depreſſion, and the ſum will be the logarithm of the number of feet required.

If the height of the obſerver be given, and the depreſſion is required, then the rule will be to the log. of the height in feet, add the conſtant log. 2.91418, and add likewiſe ten to the index, then half this ſum will be the log. tangent of the depreſſion required.

Example.

Let the height of the obſerver be 100 feet, required the depreſſion.

Log. 100 - 2.00000
Conſt. log. - 2.91418
14.91418
Log. tang. of the Depreſſion $= 9' 5'' - 7.45709$

Let the height of the obſerver be 245 feet.

Log. 245 2.38916
Conſt. log. 2.91418
5.30334
Log. tang. $7.65167 = 15' 25''$ = depreſſion required, the ſame as in Mr. Mendoza's table.

Having found the depreſſion for one foot $= 59''.1$, a table may be conſtructed by multiplying $59''.1$ by $\sqrt{\text{height of the obſerver}}$.

Example.

Log. $59''.1$ 1.77150
$\frac{1}{2}$ Log. 245 1.19458
$2.96616 = 925'' = 15'\ 25$. The ſame as above.

Table of the Depreſſion of the Horizon of the Sea.

The formulæ on a ſpheroid would be a little different from the above, but the corrections are too ſmall to be of any

practical utility. Nevertheleſs, it will be adviſeable in delicate inveſtigations, to attend to the nature of the curvature between the two ſtations. This may be eaſily done by the tables inſerted under the article DEGREE, where the radius of curvature is given both for the meridional and perpendicular degree.

Example. Let the latitude = 50°

Required the depreſſion at 5000 feet elevation in the direction eaſt or weſt; and likewiſe north and ſouth.

DEPRESSION *of the ſun*, or *of a ſtar*, is its diſtance from the horizon, below it, meaſured by an arch of the vertical circle, intercepted between it and the horizon.

DEPRESSION, in *Geology*, ſignifies either a lower part of ſmall extent, in a ſtratum, as Dr. Townſon defines the term, with reference to his figure, Philoſophy of Min. p. 221; or, it ſignifies thoſe greater depreſſions, or ſinkings down, which appear in the ſtrata. Many of theſe, it muſt be obſerved, are rather a riſing up, or elevation of the ſurrounding ſtrata, than an actual ſinking down of the part, ſaid to be depreſſed. M. Sauſſure has ſuppoſed, that the lake of Geneva in Switzerland, occupies the place of a depreſſed, or ſunken maſs of primitive rock; becauſe the ſurrounding ſtrata riſe towards the lake. This, we ſuppoſe, to be no uncommon caſe, but that ſo much of the Engliſh channel as lies oppoſite to the coaſt, between the chalk ſtrata at Dover, and at Beachy-Head, and the greater part of the Briſtol channel, may be conſidered as owing to depreſſions of the ſtrata, which occupy the bottoms of thoſe ſeas. See ELEVATION *of Strata*, and ABSORPTION *of Mountains*.

DEPRESSION, in *Surgery*, is the ſinking inwards of the ſkull, ſo as to preſs down upon the brain. This takes place when ſome part of the cranium has been injured by external violence. We have mentioned the ſymptoms ariſing from this cauſe, under the article COMPRESSION, to which the reader is therefore referred. See TREPANNING, and *Injuries of the* HEAD.

DEPRESSOR, in *Myology*, a name given to ſeveral muſcles, which have the power of drawing down the parts, in which they are inſerted.

DEPRESSOR *alæ naſi*, one of the muſcles attached to the cartilaginous part of the noſe. It is the depreſſor labii ſuperioris proprius of Douglas, l'inciſif moyen of Winſlow, l'abaiſſeur du nez of Bichat. It ariſes from the ſuperior maxillary bone in front of the inciſor and canine teeth, and aſcends in a ſtraight direction, to be inſerted into the ala of the noſe, where its fibres are mingled with thoſe of the compreſſor naris, and of the levator labii ſuperioris et alæ naſi.

It draws down the ala of the noſe, and the neighbouring part of the upper lip, which it preſſes againſt the teeth.

DEPRESSOR *anguli oris*, one of the muſcles of the mouth; for the deſcription of which, ſee DEGLUTITION.

DEPRESSOR *labiorum communis*; a name given by ſome to the depreſſor anguli oris, which ſee.

DEPRESSOR *labii ſuperioris alæque naſi*. See DEPRESSOR *alæ naſi*.

DEPRESSOR *labii ſuperioris proprius*. See DEPRESSOR *alæ naſi*.

DEPRESSOR *labii inferioris*, a muſcle of the lower lip, deſcribed alſo by the name of quadratus; for its deſcription ſee the account of the muſcles of the lips, in the article DEGLUTITION.

DEPRESSOR *oculi*, a name which has been ſometimes given to the inferior ſtraight muſcle of the eye. See EYE.

DEPRESSOR *maxillæ inferioris*, a name of the digaſtricus muſcle; for the deſcription of which, ſee the article DEGLUTITION.

DEPRIMENS, in *Anatomy*, a term applied to ſome muſcles which depreſs or draw down parts.

DEPRIMENS *biventer*. See DIGASTRICUS.

DEPRIMENS *humerum rotundus*, a name given by Spigelius to the teres major, which ſee.

DEPRIMENS *oculi*, the inferior ſtraight muſcle of the eyeball. See EYE.

DEPRIVATION, in the *Canon Law*, the act of bereaving, diveſting, or taking away a ſpiritual promotion, or dignity: as when a biſhop, vicar, prebend, or the like, is depoſed, or deprived of his preferment, for ſome matter, or fault, in fact, or in law. See DEPOSITION.

Deprivation is of two kinds; *à beneficio, & ab officio*.

DEPRIVATION *à beneficio* is, when for ſome great crime or defect a miniſter is wholly and for ever deprived of his living, or preferment: which differs from ſuſpenſion, in that the latter is only temporary.

DEPRIVATION *ab officio*, is when a miniſter is for ever deprived of his orders: which is the ſame, in reality, with what we otherwiſe call *depoſition* and *degradation;* and is uſually for ſome heinous crime deſerving death, and is performed by the biſhop in a ſolemn manner. See DEGRADATION.

Deprivation may alſo take place in conſequence of ſome particular clauſe in an act of parliament. The deprivation of biſhops, &c. is declared lawful by ſtatute 39 Eliz. c. 8. By the king's commiſſion, in whom the ſupremacy is lodged, a biſhop may be deprived; however, the canons direct, that a biſhop ſhall be deprived in a ſynod of the province: or, if that cannot be aſſembled, by the archbiſhop and 12 biſhops at leaſt, not as his aſſiſtants, but as judges. It has been adjudged, that an archbiſhop may deprive a biſhop for ſimony, &c. for he hath power over his ſuffragans, who may be puniſhed by the archbiſhop's court for any offence againſt their duty. (1 Salk. 134.) Deprivation may take place either, firſt, by ſentence declaratory in the eccleſiaſtical courts, for fit and ſufficient cauſes allowed by the common law; ſuch as attainder of treaſon or felony (Dyer 108. Jenk. 210.) or conviction of other infamous crimes in the king's courts; for hereſy, infidelity, groſs immorality, and the like: or, ſecondly, in purſuance of divers penal ſtatutes, which declare the benefice void, for ſome nonfeaſance or neglect, or elſe ſome malfeaſance or crime; as for ſimony (31 Eliz. c. 6. 12 Ann. c. 12.); for maintaining any doctrine in derogation of the king's ſupremacy, or of the 39 articles, or of the Book of Common Prayer (1 Eliz. c. 142. 13 Eliz. c. 12.); for neglecting after inſtitution to read the liturgy and articles in the church, or make the declarations againſt popery, or take the abjuration oath (13 Eliz. c. 12. 14 Car. II. c. 4. 1 Geo. I. c. 6.); for uſing any other form of prayer than the liturgy of the church of England (1 Eliz. c. 2.); or for abſenting himſelf 60 days in one year from a benefice belonging to a popiſh patron, to which the clerk was preſented by either of the univerſities (1 W. & M. c. 26.);—

in all which or ſimilar caſes the benefice is *ipſo facto* void, without any formal ſentence of deprivation, and avoidance by act of parliament, and no declaratory ſentence. If any parſon, vicar, &c. have one benefice with cure of ſouls, and take plurality, without a faculty or diſpenſation; or if he commit waſte in the houſes and lands of the church, called dilapidations; or if he obtained preferment in the church, by ſimoniacal contract; theſe have been held good cauſes for deprivation of prieſts. When a benefice is only voidable, but not void before ſentence of deprivation, the party muſt be cited to appear; there is to be a libel againſt him, and a time aſſigned to anſwer it, and alſo liberty for advocates to plead, and after all a ſolemn ſentence pronounced; though none of theſe formalities are required, when the living is made *ipſo facto* void. (Can. 122.) If the deprivation be for a thing merely of eccleſiaſtical cognizance, no appeal lies; but the party has his remedy by a commiſſion of review, which is granted by the king, of mere grace. (Moor. 781)

DEPTFORD, in *Geography*, is a large populous town, though not inveſted with the privilege of a market, in the county of Kent, England. Its name was anciently ſpelt *Depēford*, ſuppoſed to have been derived from a ford, through the Ravenſbourne river at this place. It was alſo formerly called *Deptford Strond* and *Weſt Greenwich*. The town conſiſts of two pariſhes, called Deptford St. Nicholas or the Lower Town, and Deptford St. Paul or the Upper Town. The latter was conſtituted a diſtinct pariſh in the year 1730. Deptford was anciently a ſmall fiſhing village, and continued of comparatively but little importance, till the Royal Dock was eſtabliſhed here by Henry VIII. in the beginning of his reign. Since that period, it has progreſſively increaſed; and its population, according to Mr. Lyſons, has augmented in the proportion of twenty to one within the laſt two centuries: though a conſiderable check was given to its increaſe in 1665 and 1666, during which years nearly nine hundred perſons died here of the plague. Deptford ſuffered ſeverely by a fire in 1652; and in 1671 the Lower Town was inundated by a flood which roſe to the height of ten feet in the ſtreets near the river, ſo that the inhabitants were obliged to retire to the Upper Town in boats: the adjoining marſhes were alſo overflowed, and about ſeven hundred ſheep, with a great number of oxen, cows, &c. were deſtroyed.

Deptford is noted for its docks, one of which, called the Royal Dock or King's Yard, was formed, as before obſerved, by King Henry VIII., but it has been greatly enlarged and improved ſince that period. All its concerns are managed under the immediate inſpection of the Navy Board: the reſident officers are, a clerk of the cheque, a ſtore-keeper, a maſter ſhipwright, and his aſſiſtants, a clerk of the ſurvey, a maſter attendant, a ſurgeon, and various inferior officers. The number of artificers and labourers employed here in time of war is about 1500: even in time of peace, the general number is upwards of 1000. The whole extent of the yard includes about thirty-one acres, which are occupied by various buildings; two wet docks, a double and a ſingle one; three ſlips for men of war; a baſon; two maſt-ponds; a model-loft; maſt-houſes; a large ſmith's ſhop, with about twenty forges for anchors; ſheds for timber, &c. The old ſtore-houſe is a quadrangular pile, and appears to have conſiſted originally only of one range of buildings on the north ſide; where, on what was formerly the front, is the date 1513, together with the initials H. R. in a cypher, and the letters A. X. for Anno Chriſti. The buildings on the eaſt, weſt, and ſouth ſides of the quadrangle have been erected at different times; and a double front, towards the north, was added in 1721. Another ſtore-houſe, parallel to the above, and of the ſame length, having ſail and rigging-lofts, was completed a few years ago; and there is alſo a long range of ſmaller ſtore-houſes, built under the direction of ſir Charles Middleton about the year 1780. The other buildings conſiſt of various workſhops and houſes for officers. Oppoſite to the yard, affixed to the ſide of a veſſel lying at anchor in the river, is a curious machine for removing and hoiſting maſts. At a ſhort diſtance from the King's Yard, cloſe to the river, is the Victualling Office, ſometimes called the Red Houſe, from its ſtanding on the ſide of a large range of ſtore-houſes, conſtructed with red bricks, which was burned down in July 1639, and all its ſtores conſumed. It was afterwards rebuilt, and included in the grant of Sayes court to ſir John Evelyn in 1726; and was then deſcribed as 870 feet in length, 35 wide, and containing 100 warehouſes. A new Victualling houſe was built on the ſpot in 1745: this new building was alſo conſumed by fire in 1749, with great quantities of ſtores and proviſions. The immenſe pile which now forms the Victualling Office has been erected at different times ſince that period, and conſiſts of many ranges of building appropriated to the various eſtabliſhments neceſſary in the important concern of victualling the navy. Beſides ſtore-houſes of various kinds, and dwelling-houſes for the principal and inferior officers, it contains a wind-mill for grinding corn, with granaries, and bake-houſes for making biſcuit, an extenſive cooperage and brewhouſe, ſpacious ſlaughtering-houſes, and houſes for curing beef, pork, &c.

Beſides the King's Yard, here are two large private docks for ſhip-building, called Dudman's and Barnard's, where men of war of 74 guns are ſometimes built. Deptford contains two churches; the oldeſt dedicated from time immemorial to St. Nicholas, the patron of ſea-faring men; the other to St. Paul. St. Nicholas' church conſiſts of a nave, chancel, and aiſles, with an embattled tower of flint and ſtone, of a date long prior to the body of the fabric, which was rebuilt in 1697. The monuments and ſepulchral inſcriptions are numerous, and many of them record the memory of perſons of celebrity. In the chancel is the monument of Capt. Edward Fenton, who accompanied ſir Martin Frobiſher in his ſecond and third voyages, and had himſelf the command of an expedition for the diſcovery of a north-weſt paſſage. St. Paul's church is a handſome ſtone fabric, erected about the year 1730, under the proviſions of certain acts paſſed in the ninth and tenth years of queen Anne, for the building of fifty new churches in and near London. It conſiſts of a nave, chancel, and aiſles, with a well proportioned ſpire at the weſt end: the roof is ſupported by columns of the Corinthian order. On the north ſide of the altar is an elegant mural monument, by Nollekins, in memory of James Sayer, eſq. vice-admiral of the white. When the act for the ſeparation of the two pariſhes was paſſed in 1730, 3,500*l.* out of the duty on coals was allotted to purchaſe lands for the maintenance of the rector of the new church; and it was alſo enacted that the churchwardens ſhould pay him 70*l.* in addition, annually, in lieu of burial fees, except when the corpſe is admitted into the church. In Deptford are ſeveral places of worſhip for congregations of various claſſes of diſſenters.

The Corporation, or Society of the Trinity Houſe, the meetings of which are now held in a handſome building on Tower Hill, was originally eſtabliſhed at Deptford in the reign of Henry VIII., and incorporated by the name of "The Maſter, Warden, and Aſſiſtants of the Guild or Fraternity of the moſt glorious and undivided Trinity, and of St. Clement, in the pariſh of Deptford Strond." The ancient hall, in which the members continued to aſſemble at this

place, was pulled down about the year 1787, on the erection of the Trinity Houſe in London; but here are ſtill two hoſpitals belonging to the corporation. The penſioners conſiſt of decayed pilots and maſters of veſſels and their widows: the annual allowance to the widows and ſingle men is about 18*l.*; to the married men about 28*l.* The charitable benefactions of this town are numerous and of conſiderable value; in all thoſe given prior to the year 1730 both pariſhes have a joint intereſt.

Various improvements have been made at Deptford ſince the twenty-ſeventh of George II., when an act was paſſed for paving and cleanſing the ſtreets, and for the better relief and employment of the poor. The bridge over the Ravenſbourne, which was formerly of wood, was rebuilt of ſtone at the ſole coſt of Charles I. in 1628, and hasbeen rendered more commodious of late years, at the expence of the pariſhioners. Here, previous to the battle of Blackheath, in the reign of Henry VII., was a ſkirmiſh between lord Dawbeney's army, and "certayne arches of the rebelles, whoſe arrowes," as is reported, ſays Hall, "were in length a full yerde." Theinhabitants of Deptford are chiefly thoſe employed in the dock-yards, or engaged in maritime purſuits of different kinds: the number in both pariſhes, as returned under the act of 1801, was 17,548; the number of houſes 3,139: but they have been ſomewhat increaſed ſince that time. An extenſive manufacture of earthen ware, called Deptford ware, is carried on in this town. The manor houſe of Deptford, with its ſurrounding eſtate, which had obtained the name of Sayes court from its being long in the poſſeſſion of the Sayes, became in 1651 the reſidence of John Evelyn, eſq. the celebrated author of the "Sylva," whoſe gardens at this place are ſaid to have been the wonder and admiration of the moſt judicious men of his time. Mr. Evelyn died in 1706. The houſe and gardens were afterwards entirely neglected, and there is not now the leaſt trace of either. The preſent workhouſe was built on the ſite in the year 1729. Lyſons' Environs of London. Halſted's Hiſtory of Kent: and the Beauties of Englaud and Wales, vol. vii.

Deptford, a town of America, in Glouceſter county, New Jerſey.

DEPTH, in *Geometry*, &c. See Altitude, Elevation, &c.

Depth *of a Sail*, denotes the extent of any ſquare or oblong ſail from the head-rope to the foot-rope; or the length of the after-leech of any boom-ſail or ſtay-ſail.

Depth *of a Squadron*, or *Battalion*, is the number of men in a file, or the number of ranks. Infantry is now generally drawn up three deep, and in the defence of a breaſt-work only two deep. The cavalry is commonly drawn up three deep, and ſometimes only two deep. See Rank.

DEPURANTIA, in the *Materia Medica*, medicines ſuppoſed to correct or evacuate the impurities which, upon any occaſion, prevail in the body; but as no ſuch ſpecific power is known in any particular medicine, except, perhaps, in mercury, in the cure of ſyphilis, the general term is groundleſs and improper, and is now exploded by medical writers.

DEPURATION, from *deburgo*, *I purify*, in *Pharmacy*, the ſame as clarification, or purification; *viz.* the purging a body of all the lees, fæces, and other craſs, coarſe, and excrementitious parts contained therein.

Fermentation ſerves to depurate liquors: ſyrups, juices, &c. are depurated by paſſing them through the manica Hippocratis, or ſtraining-bag. See Clarification.

DEPURATORIA Febris, in *Medicine*, a fever thus called by the illuſtrious Sydenham, which prevailed much in the years 1661, 2, 3, 4. This, ſays he, ſeems to be the only one, as far as I could hitherto obſerve, in which nature regulated all the ſymptoms in ſuch a manner, as to fit the febrile matter, prepared by proper concoction, for expulſion in a certain time, either by a copious ſweat, or a freer perſpiration, and upon this account I call it the depuratory fever: and in reality, continues he, I am inclined to believe, that this is the capital and primary fever of nature, as well with reſpect to the regular method which nature uſes in promoting and accompliſhing the digeſtion of the morbific matter at the appointed time, as alſo becauſe it occurs more frequently than other fevers. It ſeems alſo reaſonable to think, that the neceſſary and excellent rules left us by Hippocrates and other ancient phyſicians, are adapted to this primary fever; by means of which it is to be regulated in ſuch a manner, that the febrile matter may be prepared to make a proper criſis by ſweat.

DEPUTATION, from *deputare*, *to depute*, a miſſion of certain ſelect perſons out of a company, or body, to a prince, or aſſembly, to treat of matters in their name, or to proſecute ſome affair therein.

Deputations are more or leſs ſolemn, according to the quality of thoſe who ſend them, and the buſineſs they are ſent upon.

Deputation is not properly applied where a ſingle perſon ſends another with ſuch commiſſion; but only where a body are concerned. The parliament deputed the ſpeaker, and ſix members to preſent their addreſs to his majeſty. The chapter deputed two canons to ſolicit their affair in council.

DEPUTATUS, among the *Ancients*, was applied, firſt, to armourers, or workmen employed in the making of armour in the forges, &c. And ſecondly, to a ſort of active people, who followed the army, and in engagements were truſted to bring off, and take care of the wounded.

Deputatus, Δεπουτατος, was alſo an inferior officer in the church of Conſtantinople, whoſe buſineſs was to call perſons of condition the patriarch had a mind to ſpeak with, and to keep off the crowd where that prelate walked.

This deputy appears to have been a ſort of uſher, or tipſtaff; but he had likewiſe the care of the ſacred veſtments, in which he approached the office of a ſacriſtan.

DEPUTY, a perſon ſent, or deputed, by ſome community in their name and behalf.

Deputy is alſo frequently uſed among us for an office, or employ, not a dignity; and ſtands indifferently for a vice, or lieutenant.

Deputy, in *Law*, is one who exerciſes an office in another's right: and the forfeiture or miſdemeanor of ſuch deputy ſhall cauſe the perſon whom he repreſents to loſe his office. A principal officer may not appoint a deputy in all caſes, unleſs the grant of the office will juſtify him in ſo doing; but when an office deſcends to an infant, ideot, &c. he may make a deputy of courſe (9 Rep. 47.). A ſuperior officer muſt anſwer for his deputy in civil actions, but not in criminal caſes (2 Inſt. 191. 466.) Judges have no power to hold their courts by deputy (2 Hawk. P. C. c. 1. § 9.): recorders, however, may do it (1 Lev. 76.). Coroners cannot appoint deputies, becauſe theirs is a judicial office of truſt, annexed to their perſons (1 Lil. 446.). Sheriffs, ſtewards of a court, bailiffs of a liberty, and conſtables, are allowed to appoint deputies (Cro. Eliz. 534. 2 Danv. 482.).

Deputy *Rock*, in *Geography*, a ſhoal in the ſound of Copland, near the north-eaſt coaſt of Ireland, nearly half way between the ſouth end of Copland iſland, and Donaghadee, on which the leaſt water is eight feet. Latitude 54° 38′. Long. 5° 24′ W. from Greenwich.

DE QUIBUS *ſur diſſeiſin*, in *Law*, a writ of entry. See Fitzherb. Nat. Brev. fol. 191.

DER, a ſyllable frequently prefixed to the names of places in England. It is ſaid to ſignify that ſuch were formerly places, where wild beaſts herded together, ſo called from the Saxon *deor*, *fera*, unleſs the ſituation was near ſome river.

Der, in *Geography*, a town of Egypt; 11 miles S. of Siut.

DERA, in *Ancient Geography*, a country of Iberia, watered by the river Sicanus. Steph. Byz.—Alſo, a town of Aſia, in the interior of Suſiana.

DERAIGN. See Dereyn.

DERANOBILA, in *Ancient Geography*, a town of Carmania.

DERASNIA, in *Geography*, a town of Poland, in the palatinate of Bracklaw; 68 miles N. W. of Bracklaw.

DERAZINA, a town of Poland, in the palatinate of Lucko; 28 miles N. E. of Lucko.

DERBE, in *Ancient Geography*, a city of Aſia Minor, in Lycaonia, near Iſauria. M. d'Anville places it near a ſmall chain of mountains, detached from Taurus in the country of Iſauria called Antiochiana. It is mentioned in the New Teſtament, Acts xiv. 6. It was the ſeat of Antipater Derbæus, and the country of Timothy.

Derbe, in *Geography*, a town of Piedmont, in the duchy of Aoſta; 10 miles W. of Aoſta.

DERBENT, or Derbend, a city of Perſia, in Dagheſtan, ſituated on the weſt coaſt of the Caſpian ſea, and having a harbour; though the worſt on this ſea, becauſe veſſels can ſeldom approach the ſhore, on account of ſands and ſhoals, but are obliged to anchor at the diſtance of $\frac{3}{4}$ of a mile; the commerce is therefore inconſiderable, and the port is little frequented. It is ſaid to have been built by Alexander the Great, and called Iſkander. Czar Peter became maſter of it during the civil wars of Perſia, and the empreſs Catherine II. took it in 1780. This city forms an oblong ſquare on the declivity of an eminence, and is ſurrounded with a wall built of hewn ſtone, five fathoms high, in many places 10 feet thick, and fortified with a number of round and ſquare towers. On the higheſt point lies the fort, which nature and art have contributed to render impregnable; but it lies too high to defend the city, and too remote to cover the harbour. Derbent is the reſidence of a khan, and its inhabitants are chiefly Perſians, Tartars, and a few Armenians. Two or three Ruſſian ſhips are annually bound for Derbent; they are uſually laden with oats and rye, and carry iron, ſteel, and lead for the Leſgues and other Tartar nations, who inhabit the eaſtern chain of the Caucaſus. The neighbourhood produces ſome corn, but not ſufficient for the conſumption of the place. Shamakee, in the province of Schirvan, ſupplies this port with ſalt, and ſilk, both raw and wrought for exportation; but Baku is a more convenient harbour. Derbent was anciently denominated the Caſpian or Albanian gates, as it occupies a ſhort declivity between the mountains and the ſea. The city, if we give credit to local tradition, had been founded by the Greeks; and this dangerous entrance was fortified by the kings of Perſia with a mole, double walls, and doors of iron. The adjoining territory of Derbent is very inconſiderabte in extent, being only four German miles in length on the ſea-coaſt, and extending from one and a half to two miles inland. The northern and ſouthern boundaries are formed by the rivers Darbach and Rubas, between which lies a broad and partly marſhy level interſected by many ſmall brooks, and here and there interſperſed with beautiful and well cultivated corn-fields. N. lat. 41° 52′. E. long. 54° 30′. The variation of the magnetic needle in June 16, 1796, was 11° 41′ 20″ E.

Derbent, a town of European Turkey, in the province of Romania, 20 miles N. of Adrianople.

Derbent, a town of Perſia, in the province of Choraſan; 110 miles N E. of Herat —Alſo, a town of Perſia, in the province of Choraſan; 90 miles S. of Abiverd.

DERBICES, in *Ancient Geography*, a people of Aſia, who occupied the banks of the Oxus, and who furniſhed Darius in his conteſt againſt Alexander with 2000 horſemen.—Alſo a people of Africa, in the interior of Libya.

DERBINSKOI, in *Geography*, a Tartarian village of Siberia, in the government of Irkutſk, on the Lena, N. lat. 60° 20′. E. long. 116° 14′.

DERBY, the county and principal town in Derbyſhire, England, occupies a flat tract of land on the banks of the river Derwent, the waters of which prove eminently ſerviceable to the manufactures of this place. Derby was a place of repeated conflicts in the early periods of Engliſh hiſtory. In the year 874, it was occupied by the forces of Halfden, a Daniſh chief, whoſe head quarters were then at Rependune, now Repton. In 918, the Danes were ſtill its maſters; but the ſame year they were attacked by ſurprize, and completely routed by the heroic Ethelfleda, daughter of king Alfred, and princeſs of the Mercians. In a few years the Danes regained poſſeſſion; but were again expelled in 942 by king Edmund, and about the ſame time diſpoſſeſſed of all the principal towns in the neighbouring counties of Lincoln, Stafford, Nottingham, and Leiceſter. That Derby about this period was a place of great importance, is evident from its being mentioned in Domeſday-book as a royal borough of Edward the Confeſſor, containing fourteen mills for grinding corn, and 243 burgeſſes, forty-one of whom held twenty-four plough-gates of taxed land. The annual rent then paid was 24*l*. When William the Conqueror obtained the crown, he gave Derby, with a great rent-roll, to his illegitimate ſon, William Peverell. It was afterwards granted by Henry I. to the earl of Cheſter, and made a corporate town; but its charter has been altered at various periods. It obtained additional privileges from Henry I. and II. Richard I. and John; in whoſe time the burgeſſes were indebted to the exchequer 56 marks, for the confirmation of their liberties. In the ſame reign, they were likewiſe returned debtors in ſixty marks, and two palfreys, for holding the town of Derby at the uſual fee-farm; and 10*l*. increaſe for all ſervices, and having ſuch a charter as the burgeſſes of Nottingham. A grant was obtained from Richard I., by which Jews were prohibited from reſiding in the town. In the reign of Edward III. the corporation was deprived of its liberties, and ſummoned into one of the king's courts, to anſwer "By what authority they demanded toll, yet paid none? Why they claimed the excluſive privilege of dyeing cloth, and prohibiting cloths to be dyed in every other place within ten leagues, except Nottingham? They were alſo to declare by what right they choſe a bailiff yearly; and why they kept a fair on Thurſday and Friday in Whitſun-week, and another of ſeventeen days at the time of the feſtival of St James: to explain by what authority they had a coroner; why the burgeſſes ſhould not be ſued out of their own borough; and wherefore they held weekly markets on Sunday, Monday, Wedneſday, and Friday?" Some mutilated charters were produced in anſwer to theſe requiſitions; but the liberties of the town were not reſtored till the inhabitants had paid a fine of 40 marks, and conſented to pay an increaſe of rent. In the year 1611, James I. granted a new charter, confirming the privileges beſtowed in former reigns, and inveſting the corporation with additional

additional liberties. By this charter the bailiffs, recorder, and town-clerk, or any three of them, were privileged to hold a court of record on every ſecond Tueſday; to have the ſole return of writs, keep a quarterly ſeſſion, two courts-leet, and ſix annual fairs; to be toll-free throughout the kingdom; and receive toll from all, except the duchy of Lancaſter, which was to pay only half the ſums charged on the inhabitants of other places. In 1638, it was determined, that the authority of the two bailiffs ſhould be veſted in one perſon, to be choſen annually, and to be called mayor. The then bailiffs, Henry Millor, and John Hope, were the firſt that held that title. In 1680, the ancient charter was ſurrendered to Charles II., and a new one (the preſent) obtained at the expence of nearly 400*l.* The corporation now conſiſts of a mayor, nine aldermen, fourteen brethren, (out of whom the aldermen are elected) fourteen common-council men, a recorder, a high-ſteward, and a town-clerk. The privilege of returning members to parliament is poſſeſſed by the freemen and ſworn burgeſſes; about 700 in number. In the reign of queen Mary, a woman was burnt in this town for maintaining that the ſacrament was only a memorial or repreſentation of the body and blood of Chriſt, and that the elements were merely bread and wine. In 1592, the plague ravaged this town: and in 1665, when London was nearly depopulated by that dreadful calamity, it again broke out at Derby, and proved ſo fatal, that the country people refuſed to bring their commodities to the market-place. The inhabitants, to prevent a famine, raiſed a pile of ſtones, which received the name of Headleſs-Croſs, in an open ſpace without the town. Here the market people placed their proviſions, and retired, till the buyer, who was not permitted to touch any article, till purchaſed, had concluded his bargain, and depoſited his money in a veſſel filled with vinegar. In the rebellion of 1745, Derby was diſtinguiſhed as the fartheſt place in England to which the pretender's army reached. Their coming being expected, proper meaſures had been taken for the ſafety of the town; and nearly 600 men raiſed by ſubſcription, beſides 150 levied and maintained at the ſole expence of the duke of Devonſhire.

The ſituation of Derby, on the banks of the Derwent, renders it, as before obſerved, extremely favourable for the inſtitution, and proceſs, of manufactures which require the aid of water; and various works have been eſtabliſhed in the town, or its immediate vicinity. Their ſucceſs, however, has been greatly promoted by the judicious application of machinery; and mills on the moſt improved conſtruction have been erected for various purpoſes. Thoſe belonging to Meſſrs. Strutts, for the manufacture of cotton, are particularly ingenious; and the facility attained by them in working ſtockings, figured waiſtcoat-pieces, and many other articles, has eminently contributed to the extenſion of this branch of buſineſs. One of theſe mills is remarkable for its floors being all conſtructed on brick arches, and paved with brick, whereby it is rendered abſolutely indeſtructible by fire. This building is ſix ſtories high, 115 feet long, and 30 feet wide; it was erected in 1793, and was the firſt fire-proof mill ever built.

Beſides the cotton factories, the manufactures moſt celebrated in Derby, are thoſe of ſilk, porcelain, and ornaments, &c. of Derbyſhire ſpar and marble. The manufacture of ſilk is carried on to a great extent, and the number of men, women, and children employed in it is upwards of 1000. The work is chiefly performed by means of machines, or mills, of various ſize, and different conſtruction. The original mill, called the ſilk-mill, by way of pre-eminence, being the firſt and largeſt of its kind ever erected in England, ſtands on an iſland on the river Derwent. Its hiſtory is remarkable, as it exemplifies the power of genius, and the vaſt influence which the enterpriſes of an individual has on the commerce of a country.

The extenſive fabric which contains the machinery, ſtands upon huge piles of oak, doubly planked, and covered with ſtone-work, on which are turned thirteen ſtone arches, that ſuſtain the walls. Its whole length is 110 feet, its breadth 39, and its height 55½. It contains five ſtories, beſide the under works, and is lighted by 468 windows. In the three upper ſtories, are the Italian winding engines, which are placed regularly acroſs the apartments, and furniſhed with many thouſand ſwifts and ſpindles, and engines for working them. In the two lower rooms are the ſpinning and twiſt mills, which are all of a circular form, and are turned by upright ſhafts paſſing through their centres, and communicating with ſhafts from the water-wheel. Their diameter is between twelve and thirteen feet, and their height nineteen feet eight inches. The ſpinning mills are eight in number, and give motion to upwards of 25,000 reel bobbins, and nearly 3000 ſtar-wheels belonging to the reels. Each of the four twiſt mills contains four rounds of ſpindles, 389 of which are connected with each mill, as well as numerous reels, bobbins, ſtar-wheels, &c. The whole of this elaborate machine, for *one* only it is, though diſtributed through five large apartments, is put in motion by a ſingle water-wheel, twenty-three feet in diameter, ſituated on the weſt ſide of the building. The whole number of wheels is about 14,000. All the operations are performed here, from winding the raw ſilk, to organizing or preparing it for the weavers. The raw-ſilk is chiefly brought in ſkains or hanks from China and Piedmont; that produced in the former country is perfectly white, but the produce of the latter is of a light yellow. The ſkain is firſt placed on an hexagonal wheel, or *ſwift*, and the filaments which compoſe it are regularly wound off upon a ſmall cylindrical block of wood, or *bobbin*. To wind a ſingle ſkain is the work of five or ſix days, though the machine is kept in motion ten hours daily; ſo aſtoniſhingly fine are the filaments of which it is formed. In this part of the proceſs, many children are employed, whoſe nimble fingers are kept in continual exerciſe by tying the threads that break, and removing the burs and uneven part, ſome of which are the caſes which the ſilk-worm fabricates for its own grave, or rather for its dormitory, while nature prepares it for a new mode of exiſtence. The ſilk thus wound upon the bobbins, is afterwards twiſted by other parts of the machinery, and is then ſent to the *doublers*, who are chiefly women, ſtationed in a detached building, which ſtands on the ſame iſland, on piles like the ſilk-mill; and though not half ſo broad, is nearly thirty feet longer. Here four, ſeven, or ten of the threads are united into one, according to the uſes for which they are deſigned; the fine kind going to the ſtocking weaver; the others to the manufacturers of waiſtcoat-pieces, &c.

The manufacture of porcelain was originally eſtabliſhed at Derby about the year 1750, by the late ingenious Mr. Dueſbury; but the moſt conſiderable improvements have been effected ſince his deceaſe, through the judicious methods employed in preparing the paſte, and increaſing the beauty of the decorations. The ware itſelf is not of equal fineneſs with the French and Saxon; though its workmanſhip and ornaments are far ſuperior. The paintings are, in general, rich and well executed, and the gilding and burniſhing exceedingly beautiful. The body of the ſemi-vitreous ware, called porcelain, is fine white clay, combined with different proportions of fluxing matter. The beſt kind is abſolutely infuſible, and takes for its glaze a vitreous ſubſtance,

ſtance, without a particle of lead. When the paſte is duly prepared, by grinding and other operations, it is conſigned to the workman, whoſe dexterity produces a variety of beautiful forms from the ſhapeleſs maſs delivered to him. Round veſſels are uſually made by a man called a *thrower*, who works them on a circular block, which moves horizontally on a vertical ſpindle. From him they paſs to the lathe, and are reduced to their proper thickneſs and form at the end of an horizontal ſpindle. Afterwards they are *finiſhed*, and *handled* if neceſſary by other perſons, and are then conveyed to a ſtove where they remain till the moiſture is entirely evaporated, when they become fit for baking. Oval veſſels, ſuch as tureens, tea-pots, &c. aſſume their form by being *preſſed* into moulds of plaſter, or gypſum, by hand. The *ſaggars*, or caſes, in which the articles are burnt, are various in ſize and dimenſions. Theſe are ſet in the kiln or oven, one upon the other, and when piled up nearly to the top, have ſome appearance of piles of cheeſe. When the kiln is full, it is carefully cloſed, and the ware baked by the admiſſion of heat through horizontal and vertical flues; this is the firſt baking, and the porcelain in this ſtate is vulgarly called biſcuit. It is then dipped in glaze of about the conſiſtence of cream, and carried to the glaze kiln, where it is again baked, but in a leſs degree of heat than before. The ware is now delivered to the painters, who, with colour prepared from mineral bodies, ornament it with landſcapes or figures, according to the required patterns. After this proceſs, it is again conveyed to the kiln, and the colours vitrified, in order to fix and give them a proper degree of luſtre. Every coat, or layer of colour, requires a freſh burning; once or twice is ſufficient for the ornaments of the common porcelain, but the more elaborate decorations render it neceſſary for the colours to be laid on, and undergo the action of fire ſeveral times, before they obtain their full effect. This completes the proceſs of thoſe articles that have no gold in their pattern; but where this addition is wanted, they are pencilled with a mixture of oil and gold diſſolved, or thrown down by quickſilver aided by heat, and once more committed to the kiln; here the gold reaſſumes ſolidity, but comes out with a dull ſurface, which is quickly rendered brilliant by rubbing with blood-ſtones, and other poliſhing ſubſtances. The porcelain is now ready for uſe, but the latter part of the proceſs requires conſiderable care, as the gold, when not ſufficiently burnt, will ſeparate in thin flakes, and when over-fired, will not receive a proper poliſh. The higheſt finiſhed ware in this manufactory is frequently returned to the enamel kiln, where the colours are fluxed ſix or ſeven times; the beſt only are here finiſhed for ſale. The making of biſcuit figures, or white ware, is peculiar to this manufactory; and the pieces are ſuppoſed to be equal in beauty and delicacy to any of a ſimilar kind made in Europe. Here the lathe is of no uſe, the figures being all caſt in moulds of plaſter or gypſum, into which the materials are poured, having previouſly been reduced to a liquid of the conſiſtence and appearance of thick cream. The water contained in the mixture is quickly abſorbed by the plaſter, and the paſte becomes ſufficiently hard and tenacious to part freely from the mould. The various parts of the figures, as the head, arms, legs, &c. are caſt in ſeparate moulds, and when dried and repaired, are joined by a paſte of the ſame kind, but thinner than the former. The articles are then ſent to the kiln, and after undergoing a regular and continued heat, come out extremely white and delicate.

The original ſilk-mill, erected by Mr. Crochet, and now called the old ſhop, was afterwards converted into a cotton factory, but is at preſent in the occupation of Meſſrs. Brown and ſon, who employ it for cutting and poliſhing marble, and manufacturing the Derbyſhire fluor ſpar, or blue John, and gypſum, into a variety of beautiful ornaments, as urns, vaſes, columns, obeliſks, &c. The machinery applied to execute theſe purpoſes is of very ingenious conſtruction; and the lathes are ſo contrived, by the aſſiſtance of a reverſe motion, that they can readily be made to revolve either ſlower or faſter, as the deſign or quality of the ſubſtance under manufacture may require. They may likewiſe be ſtopped at pleaſure, without impeding the motion of any other part of the works. When the blue John is to be made into a vaſe, or any other ornamental form that renders the uſe of the lathe neceſſary, it is carved with a mallet and chiſſel, into a rude reſemblance of the object intended to be produced, and being afterwards ſtrongly cemented to a plug or chock, is ſcrewed upon the lathe. A ſlow motion is then given to the work, and a bar of ſteel about two feet long, and half an inch ſquare, properly tempered, and pointed at each end, is applied to the fluor, on which water is continually dropping to keep the tool cold, preſerve it from friction, and enable it more readily to reduce the ſubſtance upon which it acts. As the ſurface becomes ſmoother, the tool is applied with more freedom, and the motion of the lathe accelerated, till the fluor has aſſumed its deſtined form. When the turning is completed, pieces of grit-ſtone, of different degrees of fineneſs, are applied with water to bring the article to a proper ground for poliſhing with fine emery, tripoli, and putty, or calx of tin. Theſe means are continued till the fluor is incapable of receiving a higher degree of poliſh; which is known when water thrown on it will no longer increaſe its luſtre. The advantage of the lathe ſet in motion by water over thoſe worked by the foot, is ſaid to be particularly conſpicuous in forming hollow vaſes, or articles of equal delicacy. By the uſe of the foot-lathe the fluor was frequently broken, and without extreme care, its laminated texture always diſturbed; but the greater ſteadineſs given to the machinery by the water-wheel, operates as an effectual preſervation from theſe inconveniences. The great eaſe with which a ſlow or quick motion can be produced by the uſe of the water lathe, is alſo an additional advantage, and tends conſiderably to increaſe the elegance of the ornaments. The ſame wheel which gives motion to the lathes for manufacturing the fluor-ſpar, &c. is likewiſe applied to work the machinery for ſawing and poliſhing marble. On the vibrating poles to which the cranks are fixed are ſliding boxes, containing ſets of ſaws, which are nothing more than thin plates of ſoft iron, that drop as they cut the marble. Theſe are ſupplied with ſand and water; and being moveable with ſcrews, may be arranged at different diſtances, ſo that the ſlabs may be cut of any thickneſs. A ſet of ſaws conſiſts of a different number of plates, ſo that the block to which they are applied may be ſeparated at one proceſs into as many ſlabs as may be thought neceſſary. The ſlabs thus ſawn, are taken to the poliſhing bed, which has four wheels that move on a gangway with a very ſlow motion given to it by a worm and a crank. One of the ſlabs being fixed on this bed, another is faſtened above it to an arm attached to a vibrating pole, that works with a quick motion in a tranſverſe direction. The ſlabs thus moving in contact with each other, and being ſupplied with ſand and water, ſoon acquire a level ſurface, when finer materials are employed to increaſe their ſmoothneſs, and give them a higher poliſh.

Derby is divided into five pariſhes, each of which has a church. The principal ornament of the town is All-Saints church: yet, reſpectable as it is, it diſplays a remarkable inſtance of architectural incongruity. The tower was

erected:

erected in the reign of Henry VIII., and its upper part is richly ornamented with tracery, crockets, high pinnacles, and battlements; but the body is Grecian, and the interior is particularly light and ſpacious. The roof is ſupported by five columns on each ſide. The deſign of the body of the church was executed by Gibbs, the ingenious architect of St. Martin's in the Fields, London. The money for building it was chiefly procured through the indefatigable exertions of the then miniſter, Dr. Michael Hutchinſon, whoſe zeal and ſucceſs in this work are recorded on a tablet to his memory, placed againſt the ſouth wall within the church. On the ſouth ſide of the chancel is the monument-room of the Cavendiſhes; and many of that illuſtrious family are buried in the vault beneath. In this repoſitory is a ſplendid mural monument to the memory of the celebrated counteſs of Shrewſbury; it was conſtructed in her life-time, and under her inſpection. Among other monuments deſerving of notice, is one to the memory of William, earl of Devonſhire, who died in 1628, and Chriſtian, his counteſs. Another neat monument, by Nollekins, diſplays the medallion and arms of William, earl of Beſborough, who died in 1793: and on a mural monument, by Ryſbrach, to the memory of Caroline, counteſs of Beſborough, who died in 1760, is a well executed figure of that lady. Againſt the wall, on the north ſide of the church, is a curious memorial of Richard Croſhaw, who was the ſon of a poor nailor in this town, and went to London in a leathern doublet to ſeek his fortune: poſſeſſing induſtry and perſeverance, his endeavours proved ſucceſsful; and having attained conſiderable affluence, he bequeathed upwards of 4000*l.* to the corporation of Derby, for the maintenance of lecturers, the relief of the poor, and other benevolent purpoſes. He died in 1631. The other four churches of this town are reſpectively dedicated to St. Alkmund, St. Peter, St. Werburgh, and St. Michael. The firſt of theſe is ſuppoſed to have been founded at the beginning of the ninth century, in honour of Alkmund (ſon of Alured, the depoſed king of Northumberland) who was ſlain in battle while endeavouring to reinſtate his father.

The principal public buildings in Derby are a county hall, a town hall, a county gaol, an elegant aſſembly room, and a theatre. The county hall, which is a large but heavy building of free ſtone, was finiſhed in the year 1660. The town hall, built by the corporation in 1730, is a handſome ſtructure. The county gaol was erected about 1756, at the expence of the county, aided by a donation of 400*l.* from the duke of Devonſhire: it is ſituated on the eaſt ſide of the town, near the upper end of Friar gate, and is a very reſpectable building, well adapted for the purpoſe of its deſtination: the front is from an excellent deſign, diſplaying ſolidity and ſtrength, without that affectation of incongruous ornament ſo frequently exhibited in modern buildings of ſimilar character. The aſſembly room is of ſtone, and is ſituated on the north-eaſt ſide of the market place: the foundation was laid in 1763; but the edifice was not completed till 1774. The theatre ſtands in Bold lane, is built of brick, and was erected in 1773.

Derby is a very improving and populous place; and though the buildings have been continually increaſing for the laſt twenty years, they are yet inſufficient for the convenience of the inhabitants. Freſh ground is frequently broken up for new houſes, which are moſtly let before they are completed: the number of houſes, as aſcertained by the late act, was 2,144. that of the inhabitants 10,832; but both are increaſing, and there is reaſon to believe, will keep pace with the progreſſive improvements of the town, and the augmentation of its trade. Various branches of buſineſs, beſides the manufactures already mentioned, are carried on to a conſiderable extent, and ſeveral new works of magnitude have lately been eſtabliſhed. On Nun's green a bleaching-ground has been opened, in which the proceſſes are performed according to the improved methods introduced by the advancement of chemiſtry: to aid the operation, a ſmall ſteam-engine has been erected. A mill for ſlitting and rolling iron for a variety of purpoſes; a large furnace for ſmelting copper ore, with a machine for battering and rolling the copper into ſheets; a red lead manufactory; a mill for making tinned-plates, &c. are alſo exiſting in this town or its immediate vicinity. Among the modern improvements of Derby, may be included the lighting and paving of the ſtreets, and the removing of thoſe obſtructions that prevented a free paſſage. Theſe purpoſes were effected by an act paſſed in 1792, which appointed commiſſioners with full power to levy a ſmall rate on the inhabitants, and likewiſe to ſell all the common land belonging to Nun's green; the ſums thus produced to be applied in defraying the neceſſary charges. Since the above year, ſeveral of the bridges that were built acroſs the Markeaton Brook have been removed, and three new ones, of ſtone, erected by ſubſcription. An elegant bridge of three arches has likewiſe been built over the Derwent; and, together with the ſilk-mill, the weirs, and the broad expanſe of the river, forms a very pleaſing proſpect on entering the town from the Nottingham road.

Numerous bequeſts for the relief of the poor have been made at different times by benevolent perſons. One of the moſt conſiderable charities is the Devonſhire alms-houſe, founded by the counteſs of Shrewſbury in queen Elizabeth's reign, for the ſupport of eight men and four women: the old houſe was taken down about twenty years ago, and the preſent erected by the duke of Devonſhire. Science and literature meet with great encouragement at Derby: this may, in ſome degree, be aſcribed to the Philoſophical Society eſtabliſhed here about the year 1772, through the foſtering patronage of the late Richard French, eſq. and Dr. Darwin, the latter of whom for many years made this town his reſidence. Several book-ſocieties have alſo been inſtituted; and to the credit of the individuals compoſing them, the works purchaſed are chiefly of a ſcientific and philoſophical tendency.

Derby, previous to the diſſolution of religious houſes, contained a monaſtery dedicated to St. Helen, founded by Robert de Ferrariis, ſecond earl of Derby, about the middle of the twelfth century; a ſmall Benedictine nunnery, founded ſoon after the former by an abbot of Derby, and dedicated to St. Mary de Pratis; a priory of Dominicans, or Black Friars, founded towards the cloſe of the thirteenth century; and a cell of Cluniac monks, founded by Walthеof, a Saxon nobleman, dedicated to St. James, and given early in the twelfth century to the abbey of Bermondſey, in Southwark. Here were alſo an hoſpital dedicated to St. Leonard, and a maiſon-dieu, both inſtituted for the reception of lepers.

Derby is ſituated 126 miles N.W. from London; it has a weekly market on Friday, and ſeven annual fairs.

The celebrated aſtronomer John Flamſtead, is conſidered by ſome authors as a native of this town; an opinion which, though controverted, is favoured by the circumſtance of his father reſiding here.

The vicinity of Derby furniſhes a variety of agreeable walks, where the inhabitants may enjoy a ſalutary exerciſe, and a ſucceſſion of proſpects diſtinguiſhed by the ſofter features that attend cultivation. On Windmill-hill, at a ſhort diſtance from the town, a neat proſpect-houſe has lately been erected by —— Robinſon, eſq. from which the views over the adjacent country are very extenſive. Hutton's Hiſtory

of

of Derby, 8vo. Pilkington's Hiſtory of Derbyſhire, 2 vols. 8vo. Beauties of England and Wales, vol. iv.

DERBY, a townſhip of America, in Orleans county, Vermont, on the N. line of the ſtate, on the E. ſhore of lake Memphremagog.—Alſo, a poſt-town in New Haven county, Connecticut, on the point of land formed by the confluence of Naugatuck and Houſatonick rivers. This town was ſettled in 1665, and is now divided into two pariſhes, and has an academy. It has a conſiderable trade with the Weſt Indies, and in its vicinity are mills on the falls of Naugatuck, and iron as well as other works on Eight-mile river, that falls into the Houſatonick, which is navigable for 12 miles to this town. It has 1878 inhabitants.

DERBY, or DARBY, *Upper* and *Lower*, are ſituated in Delaware county, Pennſylvania; the former containing 862, the latter 980 inhabitants; ſeven miles S.W. of Philadelphia.

DERBY *neck*. See BRONCHOCELE.

DERBY *Canal* is the parliamentary name of a navigable canal in the county of Derby, which was completed in the year 1794, between the Trent river at Swarkſtone, and Little Eaton, with a rail-way extenſion thence to the collieries at Smithey-Houſes, near Denby, and a branch from the ſame to Horſley and Smalley Mills collieries. There is alſo a branch from the town of Derby to the Erewaſh canal, near Sandyacre. See CANAL.

DERBYSHIRE is a county ſituated nearly in the middle of England, at an equal diſtance from the eaſtern and weſtern ſeas. It is encompaſſed by Yorkſhire and Cheſhire to the north, and Staffordſhire, Leiceſterſhire, and Nottinghamſhire to the eaſt, weſt, and ſouth. The area is ſuppoſed to meaſure about 55 miles from north to ſouth, and 38 in an oppoſite direction, and compriſes nearly 720,640 acres of land. Of theſe above 500,000 are cultivated arable and paſture, whilſt the remainder conſiſts chiefly of bleak mountainous regions, and open commons. The whole county is divided into ſix hundreds, and contains 11 market towns, and 136 pariſhes. Theſe comprehend 33,191 houſes, and about 161,142 inhabitants.

The northern and ſouthern parts of this county exhibit a ſtriking difference and contraſt in geographical features: as the former abounds with hill and vale, and the latter preſents a flat-ſurface. The higher region is denominated the High Peak, and the latter the wapentake, or Low Peak. Among the chief eminences in this diſtrict are the mountains of Ax-edge, and Kinder-ſcout. The former is ſituated near Buxton, and was calculated by Mr. Whitehurſt to be about 2100 feet higher than the town of Derby, and 1000 feet above the valley in which Buxton-hall ſtands: the elevation of Kinder-ſcout, though not preciſely aſcertained, is ſuppoſed to be greater. The High Peak is a region of bleak barren heights, and long extended moors, interſperſed with deep vallies, through which the ſmall ſtreams take their courſe. Here the ſcenery is in many parts romantic and ſublime; though, on the whole, inferior in picturеſque effect to that of other mountainous countries. Beauty, indeed, is only reſident in the vallies; the high ground appearing dreary and deſtitute of entertainment; and in many ſituations not a ſingle houſe or tree is to be ſeen, to divert the eye of the traveller, or relieve the wearineſs that ariſes from the contemplation of ſterility and nakedneſs. The Low Peak abounds with eminences of various height and extent. Braſſington-Moor, Alport, near Wirkſworth, and Crich-Cliff, are the moſt elevated, and command very extenſive proſpects: from Alport, on a clear day, the Wrekin in Shropſhire may be diſtinguiſhed. On the eaſt ſide of the county there is alſo a high ridge of conſiderable extent, beginning to the ſouth of Hardwick, and continuing in another direction to the extremity of the county, where it enters Yorkſhire. The ſouthern part of Derbyſhire is in general pleaſant and well cultivated, but preſents no particular variety of ſcenery. The mountainous part of this county is diſtinguiſhed from the reſt, by the greater quantity of rain which falls in it. At Chatſworth, which is by no means the higheſt tract, about 33 inches of rain have been found to fall annually at a medium. The High Peak is peculiarly liable to violent ſtorms, in which the rain deſcends in torrents, ſo as frequently to occaſion great ravages in the lands; it is alſo ſubject to very high winds. Theſe cauſes, together with the elevation of the country, render it cold, ſo that vegetation is backward and unkindly. Some kinds of grain will not grow in the Peak, and others ſeldom ripen till very late in the year. The atmoſphere is, however, pure and healthful, and the higher ſituations are generally free from epidemic diſeaſes, though agues and fevers ſometimes prevail in the vallies. One diſeaſe is, however, endemic in theſe parts, and even as far ſouth as Derby; this is the Bronchocele or Derby-neck: it is an enlargement of the glands of the throat; and is a degree of the ſame diſeaſe that is known in the Alps, and other mountainous tracts. It is alſo prevalent in ſome parts of Sumatra and the Eaſt Indies.

The moſt common ſoil of Derbyſhire is a reddiſh clay, or marl; the ſouthern diſtrict is in general compoſed of it, having little or no ſtone near the ſurface: but ſome parts of this tract are interſperſed with ſmall beds of ſand or gravel; and in moiſt ſituations, land of a blackiſh colour, and looſe texture, is ſometimes met with, continuing through an extent of from 50 to 200 acres. This kind of ſoil is likewiſe found throughout the ſouthern and middle part of the extenſive tract of limeſtone, which lies on the north-weſt ſide of the county. Its colouring principle is iron; but its quality is very various in different ſituations: in ſome it contains much calcareous earth; in others it does not effervеſce with acids. The large tract on the eaſtern ſide of the county, which extends from Stanton, Dale, and Morley, to the borders of Yorkſhire, and abounds with coal, is covered with a clay of various colours, black, grey, brown, and yellow, but principally the laſt; and is in ſome places mixed with a large proportion of ſand. Similar ſoil is alſo met with in the northern extremity of the county; and in ſome parts where gritſtone is found; but in the latter ſituations, the land is more frequently of a black colour, and bituminous quality. In the vallies, near the banks of the larger rivers, the ſoil is very different from that of the adjacent parts, and has been evidently altered by the depoſitions from the inundations. Peat bogs exiſt in the north parts of the county, even on the higheſt mountains; and in ſome of them, trees have been found nearly perfect. Barley is much cultivated in many parts, but particularly in the pariſhes of Greſley and Repton, where the farmers are induced to grow it, by the conſumption of malt in the neighbouring town of Burton, whoſe famous ale has acquired ſuch extenſive celebrity. The whole produce has been calculated at about 5000 quarters annually. On the eaſtern ſide of the county the land is chiefly under tillage; but the midland tracts have a mixture of paſture and arable, according to ſituation: the moors in this diſtrict are in a courſe of progreſſive improvement. In the High Peak the grounds are chiefly appropriated to the grazing and breeding of cattle; very little corn, beſides black oats, being grown: on the more elevated parts, ſheep of the ſmaller horned kind are fed: the mutton is excellent. Little attention has been paid to the cultivation of artificial graſſes; but an uncommon ſpecies of culture, as a field crop, here practiſed is that of chamomile: about 200 acres are devoted to its

growth. A loamy ſoil is choſen for its cultivation, and, after the ground is well prepared by thorough cleanings, about the end of March, the roots of an old plantation are taken up, and divided into ſmall ſlips, which are planted in rows about eighteen inches aſunder, and at about the ſame diſtance in the rows. The plants are kept clean by frequent hoeing and weeding with the hand. In September the flowers are fit to gather: their perfection depends upon their being fully blown, without their having ſtood ſo long as to loſe their whiteneſs; the flowering continues till ſtopped by the froſts. The gatherings are repeated as often as ſucceſſions of flowers appear; but this depends very much on the ſeaſon, dry open weather furniſhing more ſucceſſions than wet or dull weather. When the flowers are gathered, they are carefully dried, either in kilns very moderately heated, or on the floors of boarded rooms, heated by ſlow fires: the object is to keep the flowers white and whole, and this is beſt effected by drying them as ſlowly as poſſible. The produce varies from two hundred weight, or even leſs, to four, five, and in ſome few inſtances, ſix hundred weight *per* acre. The price has alſo varied from 2*l.* to 7*l.* *per* cwt. The plants uſually ſtand three years, of which the firſt affords the ſmalleſt produce; and the ſecond the greateſt and beſt. When the ſame plants are continued beyond three years, the ground becomes foul, and the flowers weak. When dried, the flowers are packed in bags; and afterwards ſold to perſons in the neighbourhood, who tranſmit them to the druggiſts in London.

For the botanical character and medicinal properties of chamomile, ſee ANTHEMIS.

The incloſures of Derbyſhire are very numerous, and are annually extending. Within the laſt twenty or twenty-five years, more than one-fourth of the county has been incloſed, and the rent in many inſtances nearly doubled. The ſouthern part, and the wapentake, are almoſt wholly in this ſtate; but the grounds in the High Peak are chiefly open. The former diſtricts are tolerably well provided with timber, but in this reſpect the plantations of Kidleſton park are unrivalled by any in the county.

The manufactures which are carried on in Derbyſhire are various and extenſive. With Nottinghamſhire and Leiceſterſhire, it partakes in the manufacture of ſtockings; with Yorkſhire, in that of iron, and of woollen-cloth; and with Lancaſhire, in that of cotton. To theſe may be added the manufactures of ſilk and of Derbyſhire ſpar, the latter of which may be conſidered as peculiar to this county. The buſineſs of hoſiery is chiefly confined to the parts that border on Nottinghamſhire, and to Litton, near Tideſwell. The number of frames employed, including thoſe on which ſilk and cotton ſtockings are wrought, has been calculated at about 1350. Wool is moſtly manufactured in the High Peak, adjacent to Yorkſhire. Cotton is manufactured in different modes, and in various parts of the county; but the principal factories are at Cromford, Belpar, and Derby: in the former the cotton is prepared by the machine invented by the late ſir Richard Arkwright; from ſixteen to twenty machines, on the ſame model, are alſo employed in other parts of the county. The ſilk and ſpar manufactures are nearly confined to the town of Derby.

Beſides the ſources of labour derived from the branches of commerce above enumerated, the mines of lead, iron, calamine, and coal, afford employment to many inhabitants of this county. The lead mines conſtitute a conſiderable part of the natural riches of Derbyſhire, and ſome of them have probably been worked through a long ſucceſſion of ages: their produce was formerly of greater value than at preſent; as the veins become poorer, the deeper the mines are excavated. Camden imagined that Derbyſhire was alluded to by Pliny, where he ſays, "In Britain lead is found near the ſurface of the earth in ſuch abundance, that a law is made to limit the quantity that ſhall be gotten." However this may be, we have deciſive evidence that the Romans had lead works in this county, as ſeveral pigs of lead have been found with Roman inſcriptions. The firſt of theſe was diſcovered on Cromford Moor, in the year 1777, on which the following ſentence was legible: IMP. CAES. HADRIANI. AVG. MEI. LVI. That the lead mines of Derbyſhire were known to the Saxons, is apparent from the mine near Caſtleton, called *Odin*, from the name of one of their deities: the ſame circumſtance implies that it was opened previous to the introduction of Chriſtianity into Britain. It appears alſo, that there were lead mines in the wapentake of Wirkſworth, in the year 835; for at that period Kenewara, abbeſs of Repton, granted her eſtate at Wirceſworth to Humbert the alderman, on condition that he annually gave lead of the value of 300 ſhillings to archbiſhop Ceolnoth, for the uſe of Chriſt-Church, Canterbury. At the time of the Norman ſurvey, the buſineſs of the lead mines was undoubtedly carried on to a conſiderable extent, as no leſs than ſeven mines in this county are mentioned in the Domeſday book.

Veins of lead ore are diſtinguiſhed on account of their various poſitions in the earth, by the different names of pipe, rake, and flat works. Pipe-works lie between two rocks or ſtrata, yet ſeldom follow any regular inclination, but fill up fiſſures, the lines or branches running parallel to each other, and more or leſs horizontally. The veins are ſometimes twenty or thirty yards wide, and ſometimes not more than two inches: they moſt commonly have toad-ſtone in the vicinity, either above or below. Rake, or perpendicular veins, are found in the clefts and chaſms of the lime-ſtone; and conſequently, inſtead of extending uniformly between the ſame ſtrata, they follow the directions of the cavities, and ſometimes penetrate 150 or 200 yards into the earth. The flat-works bear a great reſemblance to the pipe; yet diſagree in ſome circumſtances. The principal leader or ſtem in the pipe is accompanied with many branches, but the flat has none; the latter ſpreads wider, yet ſeldom extends more than 100 yards. It is alſo found near the ſurface, and in the ſolid rock. The miners are divided in opinion whether the pipe or rake veins are moſt prevalent.

The greateſt impediments to working the mines are foul air, and water. To relieve them from the firſt, a pipe or tube is generally introduced down the ſhaft, and extended along the roof of the gallery, to the place where the work is carried on. To remove the water many adits, or, as they are here termed, ſoughs, have been driven from the bottom of ſome neighbouring valley, and made to communicate with various works by different channels or galleries. The longeſt adit in Derbyſhire is at Youlgrave, running from the Derwent to Alport, and called the Hilcar ſough. This coſt upwards of 50,000*l.* It relieves a conſiderable number of mines, and is nearly four miles in length. Another, and one of the moſt conſiderable at Wirkſworth, is called Cromford ſough. This is full two miles in length, and was driven at an expence of 30,000*l.*

The annual produce of lead from the Derbyſhire mines cannot be exactly aſcertained, but may be eſtimated at an average of between 5000 and 6000 tons. The trade has been generally conſidered to be on the decline, as the increaſe of depth renders the mines more difficult to be worked, as well as more expenſive; yet, from the improvements that have been made in the art of ſmelting, and the more effectual mode employed to relieve the mines from water, by the driving of

new

new levels, and the erection of ſome improved fire-engines, advantages have been obtained, which, to a certain extent, counterbalance the augmented expences.

Iron-ſtone, or oxyd of iron, is found in this county in great abundance; it occurs throughout the whole diſtrict in which coal has been diſcovered, the Chinley hills excepted. The depth at which it lies from the ſurface is various, but frequently, from the great dipping of the ſtrata, it *baſſets* out *to-day*, as they here term it. In this caſe a hole is made like the ſhaft of a coal-pit, which is gradually enlarged as it is carried deeper, till the cavity aſſumes the ſhape of a bell. Theſe are ſeldom ſunk lower than eighteen or twenty yards; when at that depth freſh ground is broken, and new openings made, of ſimilar depth and form. From this practice the land receives greater injury by working iron mines, than thoſe of coal; and it is, therefore, not judged expedient to dig for iron ore, unleſs the beds are very rich. Their thickneſs varies from two to twelve inches. The quantity of iron annually produced in this county amounts to between fifteen and ſixteen thouſand tons. See IRON.

The chief places at which calamine is obtained, are Caſtleton, Cromford, Bonſall, and Wirkſworth. It occurs at various depths, but is generally found near a vein of lead ore: ſometimes the two minerals are mixed, or run a conſiderable way by the ſide of each other; but more frequently, one ceaſes where the other begins, and a good vein of both is never found in the ſame place. The quantity prepared annually in this county is about 500 tons. In the crude ſtate, its value is from three to four pounds a ton; but when refined, it is ſold at nine or ten pounds. By the various proceſſes it undergoes before it becomes ſaleable, it loſes about eight parts in twenty. See CALAMINE.

Coal was obtained in Derbyſhire ſo early as the reign of Edward II., both in the liberties of Norton and Alfreton. This is evinced by the grant made to the monks of Beauchief abbey by the lord of Alfreton, Thomas de Chaworth, who gave them licence to ſupply themſelves with this ſubſtance in any quantity they thought proper, from either of the above places. It is found at different depths, and in ſome ſituations ſeveral beds are perforated by one ſhaft; but the upper ones are of inferior quality, and ſeldom worked. Here, as in Cumberland, the vein of coal is frequently ſeparated, or broken, by ſome intervening ſubſtance, moſtly clay; and the coal on one ſide is ſometimes found lifted up or caſt down ten or twenty yards from its level, on the other. Beſides the home conſumption of coal, which is very great, large quantities are annually ſent to Sheffield; and by the different canals more is conveyed into Leiceſterſhire, Nottinghamſhire, Lincolnſhire, and Northamptonſhire.

Derbyſhire alſo abounds with metallic ores, foſſils, and various mineral ſubſtances; but it would exceed our limits to particularize all. Thoſe who wiſh for ſuch information are referred to Mawe's Mineralogy of Derbyſhire, and the Beauties of England and Wales, vol. iii.

The mineral and medicinal waters of Derbyſhire are, as might be expected in a country abounding with foſſils, numerous. All thoſe of a chalybeate and ſulphureous nature ariſe in beds of ſhale, and probably derive their impregnation from this ſubſtance; the warm ſprings alſo are obſerved to appear near theſe beds, though they break out in the ſtratum of lime-ſtone almoſt excluſively. The moſt celebrated warm ſprings are thoſe at Matlock and Buxton; they occur likewiſe at Stony Middleton; and Middleton, near Wirkſworth, had formerly a ſpring of this deſcription, which was cut off ſome years ſince by driving a ſough to remove the water from ſome lead mines in the vicinity. Thoſe of Matlock and Buxton have obtained much celebrity for their medicinal properties, and are annually viſited by a conſiderable afflux of company, who reſort to them as well for pleaſure as for health. The natural hiſtory of the Matlock and Buxton waters occupied much of the attention of the late Dr. Darwin, whoſe death has deprived ſociety of one of its moſt valuable members, and ſcience of one of her moſt diſtinguiſhed ſons. His principal obſervations on this ſubject were contained in a letter written to the Rev. Mr. Pilkington, and publiſhed in the "View of Derbyſhire." Among the arguments which have been adduced reſpecting the origin of warm ſprings, the doctor favours the following: "That the water of theſe ſprings is raiſed in vapour by ſubterraneous fires deep in the earth, and that this vapour is condenſed under the ſurface of the mountains in the vicinity of ſprings."

Amongſt the ſulphureous waters of Derbyſhire, that which is higheſt in repute riſes in the park of lord Scarſdale, at Kidleſton. In a glaſs it looks very clear and tranſparent; but in the well it appears of a blackiſh blue colour, tinged with purple, and any ſubſtance thrown into it aſſumes the ſame appearance. It is principally valued for its antiſcorbutic qualities. When taken inwardly it acts as a diuretic, and has given relief to perſons afflicted with the gravel. It has alſo been found efficacious, from external application, in various cutaneous diſeaſes, but more eſpecially in ulcerous complaints. The temperature of the ſpring is about forty-ſeven degrees. Several other ſulphureous ſprings riſe in different parts of the county, but have hitherto undergone very little examination.

The chalybeate waters are numerous, but the moſt celebrated ſpring of this nature is at Quarndon, about three miles from Derby. Perſons of a weak and relaxed habit have been much benefited by its uſe: when taken in ſufficient quantity, it generally operates as a cathartic; yet to produce this effect, exerciſe is ſometimes neceſſary. Its temperature is nearly forty-nine and an half. Within 200 yards of the warm ſpring at Buxton, there is a chalybeate water of properties nearly ſimilar to that at Quarndon. Other chalybeate waters are found at Morley, Cheſterfield, Tibſhelf, Duffield, and Bradley.

In the liberty of Heage, about midway between Crich and Belpar, is a martial vitriolic ſpring, the only one that has yet been found in this county. It is ſituated in a black boggy ſoil, and was accidentally diſcovered about thirty-ſix years ago.

The principal rivers of this county are the Trent, the Derwent, the Dove, the Wye, the Errewaſh, and the Rother.

Derbyſhire is ſituated in the dioceſe of Lichfield and Coventry, and ſends four members to parliament, *viz.* two for the county, and two for the county-town. Pilkington's View of Derbyſhire, 2 vols. 8vo. Mawe's Mineralogy of Derbyſhire, 2 vols. 8vo. Beauties of England and Wales, vol. iii.

DERBYSHIRE *Spar*. See FLUOR-SPAR.

DERCETO, or ATERGATIS, in *Mythology*, a Syrian goddeſs, ſuppoſed, by many learned perſons, to be the ſame with *Aſtarte*. See ASTARTE, and ATERGATIS.

DERDER, in the *Materia Medica of the Ancients*, a name uſed by Avicenna and Serapion, to expreſs the common elm, whoſe bark they uſed on many occaſions.

DERE, or DIRE, in *Ancient Geography*, a maritime town of Ethiopia, ſituated on a promontory of the ſame name, at the entrance of the Arabic gulf, now cape *Bab-el-Mandeb*.

DEREA, a town of the Peloponneſus, in Arcadia. Steph. Byz.

DEREFELD, in our *Old Writers*, is uſed for a park, *q. d.* a field of deer.

DEREGE, in *Geography*, an iſland of the Red ſea: low and covered with graſs; but round like a ſhield, whence its name. It lies between the ports of Sibt and Djezan.

DEREHAM, East, or *Market-Dereham*, is a market town and pariſh in the hundred of Midford in the county of Norfolk. It is 16 miles from Norwich, and 101 north-eaſt from London. In the year 1801, it contained 518 houſes, and 2505 inhabitants. This place has ſuſtained conſiderable injury by fires; firſt in the year 1581, when nearly the whole town was deſtroyed; and again in 1679, when about 20,000 *l.* worth of property was conſumed. The houſes ſince built have been rendered more commodious, and the town by paving, &c. more pleaſant. A nunnery is ſaid to have been founded here in 700, and deſtroyed by the Danes in 974. The manor is called Dereham-Reginæ, and is inveſted in the crown. Here are a weekly market on Friday, and two annual fairs. The pariſh-church is an ancient building: and contains ſome curious relics. William Cowper, the poet, was buried here in 1800. In the town are three modern meeting houſes. Blomefield's Hiſtory of Norfolk.

DEREIGNMENT, or Deraignment, in *Law*. The ſubſtantive dereinment is ſometimes uſed in the ſame ſenſe with the French defrayer or defranger; that is, to diſplace or ſet out of order. Thus we find deraignment or departure out of religion, ann. 31 Hen. VIII. c. 6. and 5 and 6 Edw. 6. c. 13. Thus alſo we meet with dereinment or diſcharge of their profeſſion, 35 Henry VIII. cap. 29. which is ſaid of thoſe religious men who forſook their orders or profeſſion. See Kitchin, fol. 152. The leſſee enters into religion, and afterwards is deraigned. And Briton, c. 21. uſes ſemonenſe defrenable, for a ſummons that may be challenged as defective, or not lawfully made. Skene, De Verb. Signific. verbo diſrationare, makes it ſignify what we call waging and making of law.

DERELICTS, from *de*, and *relinquo*, I leave, in the *Civil Law*, are ſuch goods as are wilfully thrown away, or relinquiſhed by the owner.

Derelict is alſo applied to ſuch lands, as the ſea receding from, leaves dry, and fit for cultivation.

If they are left by a gradual receſs of the ſea, they are adjudged to belong to the owner of the adjoining lands: but when an iſland is formed in the ſea, or a large quantity of new land appears, ſuch derelict lands belong to the king. See on this ſubject the article Alluvion.

DERELSIDE, in *Botany*, a name by which ſome authors have called the tamarind-tree. Alpin Egypt. p. 328.

DEREMISTÆ, in *Ancient Geography*, the name of a people who inhabited the interior of Illyria.

DEREMMA, a town of Aſia, in Meſopotamia.

DERENBURG, in *Geography*. See Dernbourg.

DERENPERG, a town of Germany, in the archduchy of Auſtria; three miles S. of Ebenfurth.

DEREON, in *Ancient Geography*, a ſmall place of Thrace, upon the Euxine ſea, at the extremity of Macron-Tychos.

DERETINI, a people of Illyria, placed by Ptolemy in Dalmatia.

DEREVIANNOE, in *Geography*, a town of Ruſſia, in the province of Uſting, on the Vitchegda; 76 miles E. of Uſt Siſolſk.—Alſo, a town of Ruſſia, in the government of Olonetz, on the W. coaſt of lake Olonetz; 12 miles S. of Petrovadſk.

DE REVOCATIONE Parliamenti, the name of a writ for recalling a parliament. Thus in 5 Edw. III. the parliament being ſummoned, was recalled by ſuch a writ before it met. Vide Pryn's Animad. on the 4 Inſt. f. 44.

DEREWNEA, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 42 miles E. N. E. of Novogrodek.

DEREYN, or Deraign, diſrationare vel dirationare, in our *Old Laws*, is generally uſed for the act of proving: thus we find dirationabit jus ſuum hæres propinquior. Glanv. lib. ii. c. 6. And, dirationavit terram illam in curia mea. Id. lib ii. c. 20. Bracton uſes it in the ſame ſenſe. Habeo ſufficientem diſratiocinationem et probationem, lib. iv. tract 6. c. 16. And ſo he makes uſe of diſrationare, lib. iv. c. 22. And we find to dereyn the warranty in Old Nat. Br. fol. 146. To deraign that right, 3 Edw. I. c. 4, and. Weſtmin. tom. ii. c. 5. When the parſon of any church is diſturbed to demand tithes in the next pariſh, by a writ of indicavit, the patron ſhall have a writ to demand the advowſon of the tithes, being in demand; and when it is deraigned, then ſhall the plea paſs in the court Chriſtian, as far forth as it is deraigned in the king's court.

DERG, in *Geography*, a river of Ireland, which riſes in the county of Donegal, and having paſſed through a lake of the ſame name, enters the ſouth-weſtern angle of Tyrone, and after a courſe of a few miles, unites its waters to thoſe of the Mourne.

Derg, *Lough*, a lake of Ireland, in the ſouthern part of the county of Donegal, which contains ſeveral iſlands, one of which is remarkable for St. Patrick's purgatory. This iſland is but 126 yards long by 44 broad, and the cave, which is called the purgatory, is 16 feet and a half by two wide, and ſo low that a tall man cannot ſtand erect in it. It holds exactly nine perſons; and a tenth could not remain in it without great inconvenience. The floor is the natural rock, and the whole is covered with large ſtones and ſods. It was imagined in the dark ages, that "whoever repented and was armed with true faith, and entering that pit continued there a night and a day, ſhould be purged from all his ſins, and alſo during his abode there, ſhould not only ſee the pains of the damned, but the joys of the bleſſed." There were alſo in the iſland a monaſtery for regular canons of St. Auſtin, ſeven chapels, and ſix churches dedicated to St. Patrick and other ſaints. The cell was demoliſhed in 1497, by order of pope Alexander VI., and in 1630, the lords juſtices ordered it to be broken open; the monks were driven away; and it was left in ruins. The place, however, ſtill continues to be frequented in the month of May, June, and July. This iſland, the lake, and river, are all ſuppoſed by ſome antiquaries to have derived their name from *dearg* or *dirg*, a cave, and the cave to be ſpoken of in the Puranas of the Indian Bramins. Mr. Wilford conſiders Ireland as the Suvarneya of the Puranas. Suvarneya was from the earlieſt periods conſidered as the abode of the Pitris (*i. e.* fathers or manes). A place where the pitris could be ſeen, is poſitively declared to be a narrow cave in a ſmall iſland in a lake, the waters of which were bitter. In it was the entrance of the Dirghe, or long paſſage into the infernal regions, which is often mentioned in the Puranas. The name Dirghe, and the deſcription of the cave, certainly much reſemble that in Ireland, whilſt the change of Pitris to Patricius is leſs difficult than many changes which have occurred in proper names. Still it ſeems incredible that Ireland ſhould have been known to the Indians, and connected in any way with their fables. Ware and other antiquarians maintain the Pagan origin of the ceremony, and Dr. Ledwich, who denies that ſuch a perſon as St. Patrick ever exiſted, ſuppoſes the ſtory of the cave to be "a pagan tale of purgatory trumped up with every circumſtance that could work on the hopes and fears" of the Iriſh, ſo as to render them more obedient to papal authority. Here then the learned doctor

and his reſpectable antagoniſt (general Vallancey) are not much at variance, could the former admit the oriental origin of what both conſider as a relict of paganiſm. The moſt diſcouraging circumſtance attending diſcuſſions of this kind, is, that as on one hand, after much labour employed in inveſtigation, certainty cannot be attained, ſo on the other, if it could, it would be attended with no practical benefit. For, of what conſequence is it, whether the purgatory were an eaſtern or weſtern fable; whether it originated with a real St. Patrick, or was a fiction of a later age. Ledwiche's Antiquities of Ireland, Vallancey's Proſpectus of a Dictionary of the Iriſh Language.

DERGHAS, a town of Perſia, in the province of Segeſtan; 120 miles E S.E. of Zareng.

DERGUY, Le, a town of France, in the department of the Aveiron, and diſtrict of Rodez; 5 leagues S. of Rodez.

DERHAM, William, in *Biography*, a celebrated divine of the church of England, was born at Stowton, near Worceſter, in the year 1657. The elementary parts of his education he had at Blockley, but he purſued the ſtudies preparatory to his profeſſion at Trinity college, Oxford. Here he diſtinguiſhed himſelf by his induſtry and talents. In 1681, as ſoon as he had taken orders, he was appointed chaplain to lady dowager Grey Warke, and in the following year he was preſented to the vicarage of Wargrave, in Berkſhire, and in 1689 to the more valuable living of Upminſter in Eſſex. In this place he applied himſelf, with great ardour, to the purſuit of natural ſcience, in which he afterwards greatly excelled. He was ſoon noticed by the ſcholars of the age, and introduced to the Royal Society, of which he proved one of the moſt uſeful members. Among his earlieſt publications was "The Artificial Clock-Maker, a Treatiſe on Watch and Clock-Work, &c." which has gone through many editions. In the years 1711 and 1712, he was appointed preacher at Mr. Boyle's lecture, and in the following year he publiſhed, in a new form, the ſermons he had delivered, under the title of "Phyſico-Theology, or Demonſtration of the Being and Attributes of God from his works of Creation." This was followed by a work, having the ſame deſign in view, entitled "Aſtro-Theology, or a Demonſtration of the Being and Attributes of God, from a Survey of the Heavens." Theſe volumes are too well known to require from us any particular account of their contents. Few books can be put into the hands of young perſons with greater advantage. Upon the acceſſion of George I., Mr. Derham was made chaplain to his majeſty, and ſoon after appointed one of the canons of Windſor. In the year 1730, the degree of doctor of divinity was conferred on him by the univerſity of Oxford. The other works of Dr. Derham were entitled to the applauſe of every friend to virtue and religion. He lived highly reſpected and eſteemed by his contemporaries, and has obtained for himſelf an unfading reputation. He died in the year 1735, and was buried at Upminſter. As a preacher, he is ſaid not to have excelled; his perſon was rather deformed, and his manner and delivery ungraceful, but his life and labours were rendered highly ſubſervient to the intereſt of religion and unfeigned piety. Biog. Brit.

DERIBIA, in *Ancient Geography*, a town of Aſia Minor, in Lycaonia, which had been epiſcopal under the metropolis of Iconium.

DERIVATIO, in *Rhetoric*, is a figure in which words that are derived from the ſame root come together in the ſame ſentence. The figure is repeated in the following example: "He wiſhed rather to die a preſent death, than to live a miſerable life."

DERIVATION, from *de*, and *rivus*, *a ſtream*, in *Grammar*, the affinity one word has with another, by having been originally formed from it.

Derivation, in *Phyſiology*, the drawing of a humour from one part of the body to another. It was ſuppoſed by the ancients that diſeaſes aroſe from humours flowing into and variouſly affecting the diſeaſed parts; and, conſequently, that the mode of cure conſiſted in removing ſuch humours. This they attempted, in various inſtances, by indirect means, as the application of bliſters to neighbouring parts, &c. The operation of ſuch curative methods was referred to the principle of derivation: humours in the head were ſaid to be drawn out by bliſters in the neck; and the diſcharges by the kidnies, inteſtines, and ſkin, were all conſidered as ſo many outlets by which noxious humours could be expelled. The more correct views of the animal economy entertained by modern phyſiologiſts have baniſhed all thoſe viſionary notions, which are to be regarded as mere flights of fancy, and totally unſupported by either facts or reaſoning. The humoral pathology has been entirely overthrown, and the ideas of derivation, founded on that ſyſtem, have, of courſe, fallen with it. Yet the vaſcular ſyſtem ſeems to be ſubject to an influence, which may be denominated that of derivation. Where the blood-veſſels of different parts communicate together, the removal of blood from one ſet has a powerful operation in emptying the others; and ſeveral experiments ſeem to prove that this influence is much more active than we ſhould have ſuppoſed. (See the article Circulation.) This is an important point in practice, as the utility of local blood letting depends on it. This is ſtrictly local only in affections of the ſkin; in all other inſtances the blood is drawn from veſſels connected with thoſe of the diſeaſed organ; and the latter can only be influenced by the way of derivation. Thus it is, that opening the temporal artery acts in affections of the eye and brain; cupping the head or neck in diſeaſes of the brain, &c.

Derivation. See Angle.

DERIVATIVE, in *Grammar*, a word which takes its origin from another word, called its *primitive*.

Such is the word derivative itſelf, which takes its origin from the primitive *rivus*, a rivulet, or channel, out of which leſſer ſtreams are drawn; and thus *manhood*, *deity*, *lawyer*, &c. are derived from *man*, *deus*, *law*, &c.

Derivative, or *Secondary Conveyances*, in *Law*, are thoſe which preſuppoſe ſome other conveyance precedent, and only ſerve to enlarge, confirm, alter, reſtrain, reſtore, or transfer the intereſt granted by ſuch original conveyance. Theſe are *releaſe*, *confirmation*, *ſurrender*, *aſſignment*, and *defeazance*.

Derivative *Mountains*, or *ſtrata*, in *Geology*, according to Mr. Kirwan (Geol. Eſſ. 226.) are ſuch as, being formed ſubſequently to the production of organic ſubſtances, originated from diſintegration, and the principal character by which ſuch are diſtinguiſhed, conſiſts in their exhibiting vegetable ſubſtances, or petrifactions, or land-ſhells, as thoſe of ſnails, or fluviatile ſhells, with either none, or ſcarce any, marine remains: the futility of theſe diſtinctions a writer in the article Colliery has endeavoured to ſhew.

DERKUL, in *Geography*, a river of Ruſſia, which runs into the Donetz; 36 miles S. of Bielovodſk.

DERMA, in *Anatomy*, a name given to the cutis, or true ſkin. It is derived from δερω, *I excoriate*. See Integuments.

DERMATO-LOGIA, a diſcourſe on the ſubject of the ſkin; from δερμα, *the ſkin*, and λογος, *a diſcourſe*.

DERMATODEA, in *Botany*, Ventenat Tabl. v. 2. 34. A genus formed by Ventenat of the *Lichen caninus*, and

and its near allies (Dill. Muſc. t. 27, 28. f. 102—109.) called by Acharius *Peltidea*. The former erroneouſly comprehends *L. pulmonarius* under this genus, which is otherwiſe tolerably natural, and will probably be retained under its Acharian name.

DERMBACH, or THERMBACH, in *Geography*, a ſmall and anciently fortified town of Germany, in the biſhopric of Fulda, and circle of the Upper Rhine, which now belongs to the new kingdom of Weſtphalia.

DERMESTES, in *Entomology*, a genus of coleoptera. Theſe have the antennæ clavate, the club perfoliated, and three of the joints thicker than the others: the thorax convex and ſlightly margined: head inflected and concealed under the thorax. Linn. Gmelin divides the dermeſtes genus into two families; the firſt including thoſe with the jaw biſid, the other ſuch as have the jaw armed, with a ſingle tooth. In the Entomologia Britannica of Marſham they conſtitute three families, one of which is diſtinguiſhed by having the body oblong; the two other have the body ovate, but one has the extreme joint of the antennæ obtuſe, and the other rather pointed. The Linnæan genus dermeſtes contains a number of inſects, deſcribed by Thunberg under the title of Anobium, and of the Ips of Olivier, and Ligniperda of Pallas. Fabricius forms ſeveral genera of the Linnæan dermeſtes.

The greater number of the dermeſtes tribe ſubſiſt in the larva ſtate on the dried ſkins of animals, and indeed on almoſt any kind of animal ſubſtances; they are exceedingly deſtructive to leather, and alſo to timber, and ſome of the ſpecies are too well known from the havoc they occaſion among books and furniture. A few kinds are found on flowers.

Species.

LARDARIUS. Black; anterior part of the wing-caſes cinereous, with a black dot on each. Linn., &c.

It is this inſect chiefly that infeſts the dried ſkins, and other preparations of animals, birds, &c. preſerved in muſeums; and it is alſo found in old bacon, and other animal ſubſtances. The larva is oval and hairy, and it is in this ſtate the inſect does miſchief.

ELONGATUS. Black; wing caſes at the baſe and poſterior band livid; antennæ and legs ferruginous. Linn. Fn. Suec. Native of Europe.

UNDATUS. Oblong and black; wing-caſes with a double white waved band. Linn. Oliv. Found chiefly in rotten animal ſubſtances in Europe.

PELLIO. Black; a white ſpot on each wing-caſe. Linn. Donov. Brit. Inſ. *Dermeſtes bipunctatus*, Degeer.

The larva of this kind is oblong, and hairy, with the tail briſtly; its manners of life are ſimilar to thoſe of dermeſtes lardarius; and it likewiſe inhabits Europe.

MACELLARIUS. Black, ſmooth; legs pitchy. Fabr. Reſembles D. lardarius, and is found in Germany.

CADAVERINUS. Black; mouth ferruginous. Fabr. Found in St. Helens; the antennæ are brown with the club ferruginous, and the abdomen cinereous beneath.

CARNIVORUS. Black; anterior part of the wing-caſes teſtaceous; abdomen white. Fabr.

Inhabits New Holland and New Zealand. The antennæ are brown, with the club ferruginous; head and thorax black, at the ſides grey; legs black.

TRIFASCIATUS. Ovate and black; wing-caſes with three waved cinereous bands. Fabr. *Byrrhus fuſcus*, &c. Geoffr.

Inhabits Europe. The margin of the thorax in this ſpecies is cinereous at the baſe, and the wing-caſes marked with a cinereous dot at the tip.

20. GUTTATUS. Oblong, and black with twenty white dots. Fabr.

Found in Saxony. Nine of the white dots are diſpoſed on each of the wing caſes, and one on each ſide of the thorax.

BICOLOR. Oblong and black, beneath teſtaceous; wing-caſes ſtriated. Fabr. Inhabits Germany.

DOMESTICUS. Black; wing-caſes greyiſh with black margin; thorax villous. Linn. Fn. Suec. Native of Europe.

VIOLACEUS. Blueiſh-black; thorax downy; Linn. Fn. Suec. *Clerus nigrocæruleus*. Geoff.

Frequent in decayed animal ſubſtances, and ſometimes found on flowers. A native of Europe.

RUFIPES. Blueiſh-black; thorax downy; legs rufous. Fabr. *Anobium rufipes*, Thunb.

Found in Africa, and ſeems to be a variety of dermeſtes violaceus.

RUFICOLLIS. Violaceous; thorax and wing-caſes rufous at the baſe. Fabr. Native of Africa and India.

CÆRULEUS. Blue, hairy, and linear. Fabr. *Anobium cæruleum*, Thunb. Found in the Cape of Good Hope.

HIRTUS. Deep black, and hairy. Gmel. *Lagria atra*, Fabr. Native of Europe.

FENESTRALIS. Cheſnut; head blackiſh; thorax fuſcous. Linn. *Byrrhus feneſtralis*, Müll.

Commonly found crawling on the frames of windows in the northern parts of Europe.

VULPINUS. Oblong, ſmooth, and black; ſides of the thorax cinereous downy; beneath whitiſh. Fabr. Native of the Cape of Good Hope.

FELINUS. Oblong, cinereous, downy and immaculate. Fabr.

Found in Van Diemen's land, and is nearly allied to the ſpecies Vulpinus.

MURINUS. Oblong, downy, black and white clouded; abdomen ſnowy. Fabr.

The larva is brown with the mouth deep black; and is frequent in rotten animal ſubſtances.

TESSELLATUS. Oblong and downy, fuſcous and cinereous clouded; abdomen fuſcous. Fabr.

NAVALIS. Elongated; ferruginous brown, with the eyes black. Fabr. Native of New Zealand.

SCABER. Greyiſh; thorax and wing-caſes ſcabrous. Fabr. Inhabits the ſame country as the former.

TESTACEUS. Oblong, teſtaceous; eyes and abdomen at the baſe black. Fabr. Native of Holland.

FUMATUS. Oblong teſtaceous; eyes black. Linn. Fn. Suec. *Dermeſtes roſæ*, Scop. Found on flowers in Europe.

PICIPES. Oblong blackiſh; legs pitchy. Fabr. Inhabits Saxony.

CHINENSIS. Oblong ferruginous; wing-caſes ſtriated. Fabr. Found in ſeeds brought from China.

PANICEUS. Oblong ferruginous; eyes rufous. Linn. Fn. Suec. Larva ovate, white and gloſſy. Inhabits Sweden.

FERRUGINEUS. Oblong ferruginous, and nearly cylindrical; wing-caſes abbreviated. Linn. Fn. Suec.

EUSTATIUS. Deep black, gloſſy, and very obtuſe; leſs ferruginous. Gmel. Found on fungi in the iſle of St. Euſtatius.

PEDICULARIUS. Oblong teſtaceous; wing-caſes abbreviated. Linn. Fn. Suec. Frequent on flowers in Europe.

FUSCUS. Oblong, villous, fuſcous and immaculate. Fabr. Inhabits Saxony.

TOMENTOSUS. Oblong, villous and grey; head with two brown dots. Fabr. Found in England and other parts of Europe.

SANGUI-

SANGUINICOLLIS. Elongated, hairy and violaceous; thorax and abdomen rufous. Fabr. Native of Saxony.

LIMBATUS. Fuſcous; wing-caſes dotted; border cinereous. Fabr. A ſmall ſpecies found in New Zealand.

SCANICUS. Deep black; thorax and two dots on the wing-caſes teſtaceous. Fabr. Inhabits Germany and Sweden.

COLON. Thorax at the ſides yellow; wing-caſes grey, with a black dot. Found in Europe.

SURINAMENSIS. Teſtaceous; wing-caſes ſtriated; thorax with three elevated ſtriæ, and margin denticulated. Gmel. Rolander, &c.

This is of a very ſmall ſize and oblong form, and inhabits Siberia and Surinam.

HEMIPTERUS. Wing-caſes abbreviated; exterior baſe, with the tip teſtaceous. Roland.

About the ſame ſize, and inhabits the ſame country as the preceding.

BIFASCIATUS. Black; wing-caſes with two waved yellow ſtreaks; thorax teſſellated with cinereous. Thunb. Native of the Cape of Good Hope.

INTERRUPTUS. Black; band at the baſe of the wing-caſes red and interrupted. Thunb.

BIPUSTULATUS. Deep black and gloſſy; head, thorax, and dot at the baſe of the wing-caſes red. Thunb.

MARGINATUS. Black; thorax at the ſides, breaſt, and inciſures of the abdomen white. Thunb.

PICEUS. Entirely ferruginous; wing-caſes ſtriated. Thunb. Native of the Cape of Good Hope.

CAPENSIS. Deep black and hairy; wing-caſes flexile and violet, with two white bands. *Anobium capenſe*, Thunb. A ſmall ſpecies found in the ſame country as the former.

CAFER. Black and glabrous; wing-caſes with two yellowiſh bands. Gmel. *Anobium bifaſciatum*, Thunb. Native of the Cape of Good Hope.

VIRIDIS. Green and hairy; legs red. Thunb. Native of India and Africa.

FIMETARIUS. Yellowiſh brown; thorax margined; antennæ and legs bay. Herbſt. Found on dung and flowers near Berlin.

CELLARIS. Browniſh; antennæ long; wing-caſes ſtriated. Scop. Found in Germany.

LONGICORNIS. Fuſcous; antennæ long; thorax excavated in the middle; wing-caſes dotted. Herbſt. Inhabits near Berlin, and is nearly allied to the latter.

FLAVESCENS. Ferruginous, beneath yellowiſh; head duſky; eyes black; thorax rounded. Schranck. Inhabits near Bavaria.

FULVIPES. Deep black, oblong; wing-caſes dotted; legs fulvous. Schranck. Gmel. &c.

SULCATUS. Fuſcous red; eyes black; wing-caſes ſulcated and dotted. Thunb. Native of Sweden.

FENESTRATUS. Fuſcous; wing-caſes with ſixteen pale ſpots; all the ſhanks ſpinous. Thunb. Found near Upſal.

RUBER. Red, thorax gloſſy, ferruginous black, with the ſides rufous. Thunb. A very ſmall ſpecies. Inhabits Upſal.

LINEARIS. Body and wing-caſes linear and ferruginous; head and thorax fuſcous. Thunb.

ATER. Black and ſhining; wing-caſes finely punctated; Thunb. Size of a ſmall coccinella. Found near Upſal.

BIPUSTULATUS. Black; head and thorax red; wing-caſes black with a red ſpot at the baſe. Thunb.

FASCIATUS. Black; wing-caſes with two yellowiſh waved bands of yellow. Thunb.

MURICATUS. Wing-caſes reticulated, behind retuſe and denticulated; thorax muricated and gibbous. Gmel. *Ligniperda terebrans*, Pallas. Found on the ſugar-cane in South America.

HAMATUS. Wing-caſes before the tip armed with a ſingle ſpine; anterior edge of the thorax furniſhed with two hooks, and dentated. Lives in decayed wood in Saxony.

MONACHUS. Wing-caſes obtuſe; thorax gibbous and truncated. Fabr.. *Ligniperda cornuta*, Pallas. Found on wood in South America.

JESUITA. Wing-caſes entire, and variolous; thorax truncated in front. Fabr. Native of New Holland.

INDICUS. Wing-caſes entire, and black; anterior part of the thorax ſcabrous. A ſmall ſpecies found in Coromandel.

MINUTUS. Black; wing-caſes entire, and pitchy; anterior part of the thorax ſcabrous. Fabr. Native of New Zealand.

EXILIS. Wing-caſes entire and pale, the whole margin black. Fabr. Found in Germany,

VILLOSUS. Thorax villous; wing-caſes entire and fuſcous. Fabr. Native of Saxony.

PALLIPES. Oblong, flat, deep black and gloſſy; antennæ and legs teſtaceous. Fabr.

LUNATUS. Oblong, and black; a cinereous lunule on the back of the wing-caſes. Fabr. A ſmall ſpecies found under the bark of trees in Sweden.

RUFICORNIS. Fuſcous; head retracted; antennæ and legs rufous. Linn. Native of Europe.

RUFIPES. Black; wing-caſes ſtriated; ſhanks and feet rufous. Marſh. Ent. Brit.

FLAVESCENS. Teſtaceous and downy; eyes black. Marſh. Ent. Brit.

4-MACULATUS. Black; wing-caſes with two black ſpots on each. Marſh. Ent. Brit.

SORDIDUS. Dull pitchy; head black; wing-caſes ſtriated. Marſh. Ent. Brit.

ATRICAPILLUS. Teſtaceous rufous; head deep black; wing-caſes teſtaceous and ſtriated. Marſh. Ent. Brit.

CONVEXUS. Black; head and thorax convex. Marſh. Ent. Brit.

CONCINNUS. Deep black and ſhining; thorax and margin of the wing-caſes teſtaceous. Marſh. Ent. Brit.

HYPOMELANUS. Rufous; abdomen black. Marſh. Ent. Brit.

CASTANEUS. Deep black; wing-caſes cheſnut. Marſh. Ent. Brit.

PALLIDUS. Teſtaceous and pubeſcent; wing-caſes punctured. Marſh. Ent. Brit.

DERMONES, in *Ancient Geography*, a people of Interior Libya.

DERNBACH, in *Geography*, a ſmall town of the grand duchy of Heſſe Darmſtadt, in Germany, in the circle of the Upper Rhine, nine miles of Marpurg.

DERNBURG, or DERENBURG, a ſmall town of Germany, in the principality of Halberſtadt, on the river Holtzemme; ſix miles S.W. of Halberſtadt. It now belongs to the new kingdom of Weſtphalia.

DERNE, probably *Derrhis extrema*, according to Strabo and Ptolemy, a town of Africa, and capital of a diſtrict of the ſame name, in the country of Tripoly, near the coaſt of the Mediterranean: the reſidence of a Sangiac. This place was formerly much more conſiderable than it is now, and it was built by the Moors, after they were driven out of Andaluſia. It ſtands about half a mile from the ſea, and is ſurrounded by ſome ſprings of ſweet water; ſo that it is a territory capable of bearing ſome corn and garden-ſtuff, nevertheleſs it is poorly inhabited. The diſtrict extends from cape Bomb eaſt, to the gulf of Benguſi weſt, above 100

leagues and ſtill farther inland. It is chiefly inhabited by wandering Arabs, to the amount of 30,000 families, who pay a ſmall tribute to the bey of Tripoly. It is almoſt every where covered with a kind of plant or ſhrub, which bears a downy leaf, and a yellow flower that blows the greateſt part of the year. The bees chiefly feed upon this flower, which gives an excellent taſte to their honey. N. lat. 32° 55′. E. long. 22° 55′.

DERNETAL. See DARNETAL.

DERNIER RESSORT, in *Law*, &c. See RESSORT.

Whatever power is committed by the king to any other, the dernier reſſort is ſtill remaining in himſelf; ſo that he may ſit in court and take cognizance of all cauſes: except in treaſons, and other caſes, where he himſelf is a party.

DERNIS, or DERNISCH, in *Geography*, a town and fortreſs of Dalmatia, ſituated on a mountain near the river Kerka, taken from the Turks by the Venetians in the year 1684.

DEROGATION, from *derogo*, an act contrary to the preceding one, and that annuls, deſtroys, and revokes it, either in whole, or part.

Derogations, in general terms, are not regarded in judicature; they muſt be in ſpecific, and in formal terms.

A new law imports a derogation of a former one: a ſecond teſtament is a derogation of a firſt.

DEROGATORY, a clauſe importing derogation.

By the French law, if a perſon own himſelf indebted in a certain ſum; notwithſtanding any quittance he has obtained for the ſame, the act is derogatory.

DEROTE, in *Geography*, a town of Egypt, ſituated in an iſland formed by the canal between Cairo and Roſetta. N. lat. 30° 40′. E. long. 31° 44′.

DERPT. See DORPAT.

DERRA, a town of Arabia, in the country of Yemen; 46 miles S.E. of Loheia.

DERRHA, or DERRHINI, in *Ancient Geography*, a place of the Peloponneſus, in Laconia, which gave name to the temple of Diana Derrheatis. Steph. Byz. It was ſituated on mount Taygates, in the vicinity of the town of Lapithæa, according to Pauſanias. It had a ſtatue of Diana.—Alſo, a town of Macedonia, on the Thermæan gulf. Pliny.

DERRHÆ, a people of Arabia Felix. Ptolemy.

DERRHIMA, a town of Aſia, in Syria.

DERRHIS, a promontory of Africa, in Marmarica. See DERNE.

DERRICK, in *Ship Rigging*, a tackle uſed at the outer quarters of a mizen-yard, conſiſting of a double and ſingle block, connected by a fall: alſo, a diagonal ſhore, as a ſupport to ſheers; alſo, a ſingle ſpar, top-maſt, or boom, raiſed upright and ſupported by guys at the head, from whence hangs a tackle over the hatchway, the heel working in a ſocket of wood, faſtened on the deck.

DERRIK, in *Geography*, a town of Perſia, in the province of Ghilan, 150 miles N.W. of Reſhd.

DERRIS, in *Botany*, (δερρις, a ſkin, from the membranous legume,) Loureiro Cochinch. 432. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth tubular, coloured, its border erect with five notches. *Cor.* papilionaceous; petals four, nearly equal in length; ſtandard ovate; wings oblong; keel lunate; all falcate at the baſe, and ſtanding on ſlender claws. *Stam.* Filaments 10, all connected into a ſheath, equal, ſhort; anthers of two round lobes. *Piſt.* Germen oblong, compreſſed; ſtyle equal to the ſtamens; ſtigma ſimple. *Peric.* Legume oblong, obtuſe, remarkably compreſſed, membranous, ſmooth. *Seed* one, oblong, flat.

Eſſ. Ch. Cal. with five notches, coloured. Petals with thread-ſhaped claws. Legume oblong, membranous.

1. D. *pinnata*. "Climbing. Leaves pinnate. Stalks many-flowered, lateral." Lour. A climbing ſhrub found in the woods of Cochinchina. Stem long, much branched, without thorns. Leaves alternately pinnate, of numerous ſmall leaflets, which are ovate-oblong, ſquare at the baſe, ſmooth, and entire. Flowers white. The root is red and fleſhy, and ſerves to ſupply the place of the betle nut, *areca*, being chewed by the natives of the country along with the aromatic leaf of the *piper betle*, in order to render the breath ſweet, and the lips red. Lour. 2. D. *trifoliata*. "Climbing. Leaves ternate. Cluſters long, axillary." Lour. Found in woods in the province of Canton, China, where it is called *Sān leâo táu*. Stem ſhrubby, climbing, branched, without thorns, ſpringing from a long, ſubdivided, fleſhy root. Leaves ternate, ovato-lanceolate, entire, ſmooth. Flowers in long axillary cluſters, with white calyx, as well as petals. Germen with the rudiments of two or three ſeeds. Lour.

DERRY. See LONDONDERRY.

DERRY. The name of an Iriſh biſhopric in the province of Armagh, which was conſtituted in the year 1158, and was firſt called Darrich. Its greateſt length is 47, and its greateſt breadth 43 Iriſh miles, including the greateſt part of Londonderry, with a part of Donegal and Tyrone. The biſhop's patronage is conſiderable, and his revenue is the greateſt, except the primacy, being ſaid to exceed 7000*l*. *per ann.* Amongſt thoſe who have filled the ſee was Dr. Nicholſon, the author of the hiſtorical libraries of England, Scotland, and Ireland, a prelate of great erudition. The ſee of Derry contains 659 000 acres, which are divided into 48 pariſhes. By unions theſe are reduced to 43 benefices, but it is to the honour of the dioceſe that there are 51 pariſh churches and 33 glebe houſes, whilſt there is only *one* entirely without glebe. Beaufort.

DERRY, a townſhip of America, in Pennſylvania, in the county of Dauphin, on the E. ſide of Swetara creek, two miles above its confluence with the Suſquehanna, famous for its cave; containing 1666 inhabitants.—Alſo, a townſhip of Pennſylvania, in the county of Mifflin, containing 1135 inhabitants.—Alſo, a townſhip in the county of Northumberland, containing 1570 inhabitants.—Alſo, a townſhip in the county of Weſtmoreland, containing 2093 inhabitants.

DERRY, *Dery*, or *Defry*, a river of North Wales, which runs into the ocean near Dolgelly, in Merionethſhire.

DERRYFIELD, a townſhip of America, in New Hampſhire, on the E. bank of Merrimack river, incorporated in 1751, and containing 557 inhabitants; 42 miles W. of Portſmouth.

DERSÆI, in *Ancient Geography*, a people of Thrace, N. of Abdera.

DERSENA, in *Geography*, a town of Perſia, in the province of Segeſtan; 228 miles S. W. of Zareng.

DERTHA, a town of Perſia, in the province of Segeſtan; 120 miles E. N. E. of Zareng.

DERTONA, or ZORTONA, in *Ancient Geography*, a town of Italy, taken poſſeſſion of by Alboin, king of the Lombards, in the year 370.

DERTOSA, or TORTOSA, a town of Hither Spain, ſituated at a ſmall diſtance from the mouth of the Iberus. It was a colony, and made municipal by Scipio. It was under the protection of Pan.

DERVAL, in *Geography*, a ſmall town of France, in the department of the Lower Loire, near Chateaubriant, 24 miles

miles S. of Rennes. t reckons 1553 inhabitants, and is the chief place of a canton, which upon a territorial extent of 235 kiliometres, compriſes ſix communes, and a population of 7078 individuals.

DERVENTIO, Derwent, a fortified town of the iſland of Albion, belonging to the Brigantes.

DERVERAGH Lough, or *Derrivarach*, a lake of Ireland, in the county of Weſtmeath, which is ſaid to be remarkable for its bream, and other fiſh. It receives the river Inny, and ſome ſmaller ſtreams, and its ſuperfluous water is diſcharged by the Inny which falls into the Shannon. On its banks was Fahatty, to which Mortimer, earl of March, who was the intended ſucceſſor of Richard II., retired on the depoſition of that prince. On a ſmall river, near this lake, was the celebrated abby of Multifernan, at which ſeveral meetings were held previous to the inſurrection of 1641.

DERVIS, or Dervich, a name given to a ſort of monks among the Turks, who lead a very auſtere life, and profeſs extreme poverty; though they are allowed to marry. The word is originally Perſian, דרוישׁ, ſignifying a beggar, or perſon who has nothing: and becauſe the religious, and particularly the followers of Mevelava, profeſs not to poſſeſs any thing, they call both the religious in general, and the Mevelavites in particular, Derviſes, or Derviches.

The Derviſes, called alſo Mevelavites, are a Mahometan order of religious; the chief, or founder whereof, was one Mevelava. They are now very numerous. Their chief monaſtery is that near Cogna in Natolia, where the general makes his reſidence, and where all the aſſemblies of the order are held; the other houſes being all dependent on this, by a privilege granted to this monaſtery under Ottoman I. Theſe Mevelavites or Mevlevis are cloiſtered, and live together in *Tekas*, or convents, though they have liberty to go out during their hours of recreation.

The Derviſes affect a great deal of modeſty, patience, humility, and charity. They always go bare legged, and open-breaſted, and frequently burn themſelves with hot irons, to inure themſelves to patience. They always faſt on Wedneſdays, eating nothing on thoſe days till after ſun-ſet. Tueſdays and Fridays they hold meetings, at which the ſuperior of the houſe preſides. One of them plays all the while on the flute, and the reſt dance, turning their bodies round and round with the greateſt ſwiftneſs imaginable. Long cuſtom to this exerciſe from their youth has brought them to ſuch a habitude, that it does not diſcompoſe them at all. This practice they obſerve with great ſtrictneſs, in memory of Mevelava their patriarch's turning miraculouſly round, as they pretend, for the ſpace of four days without any food or refreſhment, his companion Hamſa playing all the while on the flute: after which he fell into an extaſy, and therein received wonderful revelations for the eſtabliſhment of his order. They believe the flute an inſtrument conſecrated by Jacob, and the ſhepherds of the Old Teſtament, becauſe they ſang the praiſes of God upon them. They profeſs poverty, chaſtity, and obedience, and really obſerve them while they remain Derviſes; but if they chooſe to go out, and marry, they are always allowed.

Baron De Tott ſays, (Memoirs, vol. i.) that there are two kinds of theſe monks in Turkey, very diſtinct from each other, and equally remarkable. The difference betweeu them ariſes from the difference of the rules impoſed upon them by their reſpective founders. That of the "Mewliach or Mevlevi derviſes" is to turn round, as we have already obſerved, like whirligigs, to the ſound of ſoft muſic, and ſeek a holy intoxication in the giddineſs which muſt naturally reſult from this abſurd exerciſe, if the habit of thus turning round did not preſerve them from dizzineſs and drunkenneſs, which they have recourſe to the tavern to accompliſh The rule of the other monks, named "Tacta-Tepen (beaters of boards, which perhaps at firſt were their only inſtruments) is more melancholy, and has more barbarity. It conſiſts in walking, ſolemnly in a row, one after the other, round their chapel, and pronouncing the name of God, with a loud voice and much exertion, at each ſtroke on a drum, beaten for that purpoſe; the ſtrokes on which, growing gradually quicker, become at laſt ſo rapid, that theſe wretches are forced to undergo a violent labour of the lungs, and the moſt devout never cloſe the proceſſion without ſpitting blood. Their appearance is always ſad and ſurly; and theſe monks are ſo perſuaded of the ſanctity of their practice, and ſo certain of pleaſing heaven by their howling, that they never look on the reſt of mankind but with the moſt profound contempt. All the Turkiſh monks, ſays M. Peyſſonnel, in his ſtrictures on Tott's Memoirs (Mem. vol. ii. p. 192.) are divided into two orders: *viz.* the *Mevlevis* above deſcribed, and the *Bektachis*. The latter have no convents nor fixed habitations, but wander about through the country. They often attach themſelves to the great, and accompany the pachas in their travels: being kept by them in their houſes, and obtaining great confidence and influence. Many of theſe bektachis follow the army, when it takes the field; when the Janiſſaries make any change in their motion, one of theſe begins the march. On ſuch occaſions they have commonly their feet, legs, and a part of the body naked; over their ſhoulders they throw the ſkin of a tiger, lion, or ſome wild beaſt; and carry in their hand a pike, halbert, or battle-ax; and as they march, ſing verſes in praiſe of the *orta*, or regiment of Janiſſaries, and offer up prayers for the glory of religion, and the proſperity of the empire.

The generality of Derviſes are mountebanks: ſome apply themſelves to legerdemain, poſtures, &c. to amuſe the people, others give into ſorcery and magic: but all of them, contrary to Mahomet's precept, are ſaid to drink wine, brandy, and other ſtrong liquors, to give them the degree of gaiety their order requires.

Thoſe Derviſes who have aſſurance ſufficient to avail themſelves of the general ignorance of the Turks ſet up for prophets; and if the event juſtify the prediction which they hazard, they are held in great eſteem as ſaints; and even thoſe who, for want of ſucceſs, can only paſs for fools, find, nevertheleſs, admiſſion every where. Nothing can reſiſt their effrontery, nor exceed the impoſition they practiſe on the ſuperſtitious multitude. The fanaticiſm of the public obliges the moſt enlightened perſons to ſubmit: and the moſt eminent Turks can only get rid of this rabble by giving them money, which ſerves to make them more troubleſome and more inſolent.

Beſides their great ſaint Mevelava, there are other ſaints honoured in ſome particular monaſteries; as Kiderle, greatly revered in the monaſteries of Egypt, and held by ſome to be St. George; and by others, with more probability, the prophet Elias.

The Derviſes are great travellers; and, under pretence of preaching and propagating their faith, are continually paſſing from one place to another; on which account they have been frequently uſed as ſpies.

There are alſo Derviſes in Perſia, called in that country *Abdals*, *q. d. ſervants of God*. They lead a very penurious, auſtere life, and preach the Alcoran in the ſtreets, coffee-houſes, and wherever they can meet with auditors. The Perſian Derviſes retail little but fables to the people, and are in the utmoſt contempt among the men of ſenſe and letters.

There are in Egypt two or three kinds: thoſe that are

in convents, are in a manner of the religious order, and live retired; though there are of theſe ſome who travel and return again to their convents. Some take this character, and yet live with their families, and exerciſe their trades: of this kind are the dancing Derviſes at Damaſcus, who go once or twice a-week to a little uninhabited convent, and perform their extraordinary exerciſes; theſe alſo ſeem to be a good people: but there is a third ſort of them who travel about the country, and beg, or rather oblige people to give, for whenever they ſound their horn ſomething muſt be given them. The people of theſe orders, in Egypt, wear an octagonal badge, of a greeniſh white alabaſter, at their girdles, and a high ſtiff cap without any thing round it. Pococke's Egypt, p. 178.

DERUSIÆI, in *Ancient Geography*, a people of Aſia in the Perſide, according to Herodotus. Their ſituation is not preciſely aſcertained. Some geographers place them to the north of the Perſian gulf, between the river Tigris to the weſt, and the Choaſpes to the eaſt.

DERUYTER, in *Geography*, a poſt-town of America, in Chenango county, and ſtate of New York, S. of Cazenovia adjoining. It has 310 inhabitants.

DERWENT, a river in Cumberland, England, has its origin among the monſtrous craggs at the head of Borrowdale, and after pouring its foaming ſtream over various precipices, its current is enlarged by ſeveral ſiſter branches at the bottom of that romantic chaſm through which it is daſhed from rock to rock, till it flows into the Derwent lake. At the foot of this beautiful expanſe of water, it unites with the Greata, and afterwards meanders through an extenſive tract of meadow-land, till it reaches Baſſenthwaite water, through which it purſues its ſilent courſe, and at length emerges at Ouſebridge. Again confined in a rocky channel, it aſſumes a weſterly direction, and flows through a narrow vale to Cockermouth, whence, being joined by the waters of the Cocker, it paſſes through a more open country to the ſea, at Workington. The whole extent of this river affords varied and intereſting ſcenery. This river is navigable from its mouth in the Iriſh ſea for a ſhort diſtance, and veſſels are loaded in it with coals, brought down by ſeveral rail-ways from the mines in the neighbourhood of Workington.

DERWENT, a river in Derbyſhire, England, derives its ſource in the mountainous diſtrict of the High Peak, and is increaſed by various torrents which flow from the dreary waſte that ſurrounds its ſpring. Theſe unite near Hatherſage in one ſtream, which taking a ſouthern courſe, rather inclining eaſtward, emerges from its native wilds, and paſſing through Chatſworth park, has its current enlarged by the waters of the Wye. Theſe united rivers then animate the pleaſant vale of Darley, till their channel is ſuddenly ingulphed between thoſe lofty rocks, which in their winding receſſes incloſe the romantic ſcenery of Matlock Dale.

> ——————"Here the High Tor
> Rears its mighty head, along whoſe broad bold baſe
> Impatient Derwent foams, among the craggs
> Roaring impetuous, till his force all loſt,
> Gentle and ſtill, a deep and ſilent ſtream,
> He ſcarcely ſeems to move: o'er him the boughs
> Bend their green foliage, ſhivering with the wind,
> And dip into his ſurface."

Emerging through a high portal of rocks at Cromford, the ſtream then flows through ſeveral deep vallies, till entering the cultivated vale which extends to Derby, it turns to the eaſt, and flows into the Trent on the Leiceſterſhire border near Wilne. The temperature of the water of the Derwent is obſerved to be higher than that of moſt rivers, a circumſtance which is aſcribed to the numerous warm ſprings that mix with the current.

This river was navigable from the Trent at Wilden Ferry to the town of Derby; but on the completion of the Derby canal, which opens two other water communications with the Trent river, the property in this concern was purchaſed by the canal company, and the river navigation diſcontinued. (See CANAL.) A weir of ſtone, 100 yards long, is erected acroſs this river, about $\frac{1}{3}$ of a mile below Derby bridge, (which is an elegant ſtructure of ſtone with three large flat elliptical arches.) A ſough is laid under this weir and the wharfs, for $\frac{1}{4}$ of a mile in length, with a wooden trunk over Moorledge brook, for feeding the ſouthern part of the Derby canal, independent of the Derwent river, although the canal interſects the ſame, and barges can proceed up the courſe of the river to Darley.

DERWENT *River*, in Yorkſhire: this river is navigable from its efflux into the York Ouſe river, at Barnby, to the town of New Malton, a diſtance of about 37 miles: by this navigation, about 40,500 tons of coals are annually carried up to New Malton, of which more than 20,000 tons are for burning lime from the lower beds of the chalk ſtrata of Hurlock; earl Fitzwilliam's extenſive brick-kilns near this town alſo conſume conſiderable quantities of coal. See CANAL.

DERWENT, a river of *Van* DIEMEN'S *land*; which ſee.

DERWENT *Fells*, a mountain of England, in the county of Cumberland, celebrated for its mines of black lead, a little to the ſouth of Keſwick.

DERWENT *Water*, a lake of England, in the county of Cumberland, formed by the river Derwent, about four miles long, and rather more than one wide, including ſeveral ſmall iſlands, one of which is called Derwent; the northern part of the lake is very near Keſwick.

DERXENA, in *Ancient Geography*, a country of Aſia, in Armenia, towards the ſources of the Euphrates: it is called Xerxena by Strabo and Steph. Byz.

DERY. See DERRY.

DERYCK, or DERICK, PETER CORNELIUS, in *Biography*, a painter of portraits, landſcapes, and cattle, was born at Delft in 1568, and was a diſciple of Hubert Jacobs. In Italy, whither he went for farther improvement, he ſtudied the ſtyles of the moſt eminent maſters, and at laſt fixed on Baſſan as his model. In copying and deſigning he ſpent 15 years at Rome, Venice, and other cities of Italy, where he painted a great number of pictures of different ſizes. His portraits were much admired; but thoſe pictures, which were executed in the manner of Baſſan, were peculiarly commended for good deſign, firm and fine touch, and the ſpirit of thoſe animals, which he introduced in his compoſitions. His diſtinguiſhing excellence conſiſted in his imitation of the ſtyle, manner, and tint of colouring of Baſſan; which was ſo perfect that even good judges are often deceived by ſome of the pictures of Deryck. He died in 1630. Pilkington.

DESAGUADERO, in *Geography*, a river of Peru, in the province of Chucuito, formed by the termination of a kind of bay towards the S. part of the lake Titi-caca; over which is ſtill remaining the bridge of ruſhes invented by Capac Yupanqui, the fifth Inca, for tranſporting his army to the other ſide, in order to conquer the provinces of Collaſayo. The Deſaguadero is here between 80 and 100 yards in breadth, flowing with a very impetuous current, under a ſmooth and tranquil ſurface. The Inca ordered four large cables to be made of a kind of graſs, which covers the lofty heaths and mountains of that country; which cable was the foundation of the whole ſtructure. Two of theſe cables being laid acroſs the river, faſcines of ruſhes were faſtened together and laid acroſs them. On theſe

theſe two other cables were laid, and covered with other faſcines, ſecurely faſtened, and ſo arranged as to form a level ſurface; and by this means he procured a ſafe paſſage to his army. This bridge, which is about five yards in breadth, and $1\frac{1}{2}$ above the ſurface of the water, is carefully repaired, or rebuilt every ſix months, by the neighbouring provinces, in conformity to a law made by that Inea, and ſince often confirmed by the kings of Spain, on account of its great uſe; as it is the channel of intercourſe between the provinces ſeparated by the Deſaguadero.

DESAGULIERS, John Theophilus, in *Biography*, a divine and experimental philoſopher, was born at Rochelle in France, in the year 1683, but on account of the revocation of the edict of Nantz in 1685, he was at that early period of his life brought to England. He was initiated into the learned languages under his father, who afterwards ſent him to Chriſt-church, Oxford, where he took his degrees, and entered into deacon's orders in 1710; about the ſame time he ſucceeded Dr. Keil as lecturer in experimental philoſophy. In 1712, he removed to London, where he introduced the practice of delivering lectures in the ſciences, in which he continued, with much reputation and ſucceſs, until his death. He was, ſhortly after his removal to the metropolis, elected a fellow of the Royal Society, and in the year 1716, he was made chaplain to the duke of Chandos, who preſented him to the living of Edgware, and in the following year he had the honour of delivering a courſe of lectures before the king at Hampton Court. In this buſineſs he conducted himſelf ſo very ably, and ſo much to the ſatisfaction of his majeſty, that he promiſed him ſome preferment in the church by way of remuneration for his trouble. The moſt, however, that he obtained was a ſmall living in Norfolk, worth about 70*l. per annum*. From this period till his death, which happened in 1749, he was indefatigable in his experiments in natural philoſophy; many he exhibited before the Royal Society, and communicated to that learned body various valuable papers on mechanical and philoſophical ſubjects. He had taken his degree of doctor of laws at Oxford in the year 1718, and 1734 he publiſhed, in two volumes quarto, "A Courſe of Experimental Philoſophy." After this he edited Dr. Gregory's Elements of Catoptrics and Dioptrics. He next was called on to deliver his lectures, and exhibit his experiments before king George II. and the other branches of the royal family; for this he was rewarded with a living in Eſſex. He was likewiſe appointed chaplain to Frederic, prince of Wales. In the year 1742, he publiſhed a diſſertation on Electricity, which contained every thing that was known on the ſubject at that time, for which he gained a prize given by the academy of Bourdeaux. Dr. Deſaguliers tranſlated into the Engliſh from the Latin "Graveſande's Mathematical Elements of Natural Philoſophy," which were publiſhed in two volumes 4to. Notwithſtanding the diligence of this gentleman, and the notice taken of him by the learned and the great, he died in poverty, though, perhaps, this was exaggerated by the poet Cawthorne, who, ſpeaking of the neglected Deſaguliers, ſays,

> "How he, who taught two gracious kings to view
> All Boyle ennobled, and all Bacon knew,
> Died in a cell, without a friend to ſave,
> Without a guinea, and without a grave."
>
> Biog. Brit.

DESAIGNE, in *Geography*, a town of France, in the department of the Ardeche; $5\frac{1}{2}$ leagues N. of Privas.

DESANA, a town of Italy, in the lordſhip of Vercelli; 5 miles S.W. of Vercelli.

DESARENA, in *Ancient Geography*, a country of India, on this ſide of the Ganges, according to Arrian.

DESART, in *Geography*. See Desert.

Desart, in *Cookery*. See Dessert.

DESAULT, Peter, in *Biography*, a native of Bourdeaux, where he was admitted doctor in medicine, and where he acquired reputation as a practitioner in that art, the beginning of the laſt century, was author of ſeveral uſeful practical works, which are ſtill ſought for: "Nouvelles decouvertes concernant la ſeinte, et les maladies les plus frequentes," Paris, 1727, 12mo., a ſort of family medicine; he alſo wrote treatiſes on the gout, and on the venereal diſeaſe, which latter he profeſſes to cure without ſalivating the patients. "Diſſertation ſur la pierre des reins et de la veſſie," 1736, in 3 vols. 12mo. In this he defends his practice in the venereal diſeaſe, which had been cenſured. He is averſe to cutting for the ſtone in the bladder; which, he ſays, may be diſſolved, by giving the patients the water of Bareges to drink, and by injecting it into their bladders. We know theſe waters acquired great reputation as lithontriptics, and were ſuppoſed to be as powerful in relieving the pain to which perſons ſuffering a fit of the ſtone are ſubjected, and in diſſolving ſtones lodged in the kidnies, or in the bladder, as Mrs. Stephens' medicine, lime water, and Caſtile ſoap, which began alſo to be in vogue about this time. Though it is now known the waters do not diſſolve the ſtone, they are ſtill uſed for their power in appeaſing pain. In the ſecond volume the author treats of the management of perſons bitten by rabid animals. He thinks the hydrophobia may be cured by mercurial frictions, but repeated trials have ſhewn its total inefficiency in that dreadful diſeaſe. He oppoſes, with propriety, opinions once very prevalent, that perſons in hydrophobia attempt biting their attendants, and that they make a noiſe reſembling the barking of a dog, which certainly never occur. Haller Bib. Chirurg.

Desault, Peter, Joseph, ſurgeon in chief to the Hotel Dieu at Paris, publiſhed, in conjunction with M. Chopart, "A Treatiſe on Chirurgical Diſeaſes, and on the Operations required in their Cure," in 2 vols. 8vo. in 1794. An indifferent tranſlation into Engliſh of the work, by Mr. Turnbull, was publiſhed in 1797. The work is allowed to have conſiderable merit. Deſault attended the young king of France, Lewis XVII., in the Temple. He died ſuddenly, Feb. 1795, a very few days before his patient, not without ſtrong ſuſpicions of his having been deſtroyed, to prevent his diſcloſing the horrid ſcenes it is ſuppoſed he muſt have witneſſed. The ſuppoſition is ſtrengthened by learning that Chopart and Doublet, who had alſo viſited the unfortunate prince, both of them died about four days after the death of Deſault. Gent. Magazine for the year 1795.

DESCEBESADO, in *Geography*, one of the higheſt mountains of the Chileſe Andes. See Chili.

DESCANT, from *de*, and *cantus*, *ſong*, in *Muſic*, originally ſignified an extemporaneous ſong, which was no ſooner uttered than loſt; but it was afterwards applied to the art of compoſing in ſeveral parts.

Deſcant is threefold; *viz. plain*, *figurative*, and *double*.

Descant, *Plain*, is the ground-work, or foundation, of muſical compoſition, and conſiſts altogether in the orderly placing of many concords; anſwering to ſimple counterpoint.

Descant, *Figurative*, or *florid*, is that wherein diſcords are concerned as well, though not ſo much, as concords. This may be well termed the ornamental, or rhetorical part of muſic; becauſe, that in this are introduced all the varieties

rieties of points, figures, ſyncopes, diverſities of meaſures, and whatſoever elſe is capable of adorning the compoſition.

DESCANT, *Double*, is when the parts are ſo contrived, that the treble may be made the baſs; and on the contrary, the baſs the treble. See DISCANT.

DESCENDANT, in *Genealogy*, a term relative to *aſcendant*, and applied to a perſon who is born or iſſued from ſome other referred to. Thus, mankind are ſaid to be deſcendants of Adam. The deſcendants from the brothers of the Maid of Orleans are confirmed in their exemption from all taxes and impoſts, by a regulation of the year 1634. See DESCENT.

DESCENDENS, OBLIQUUS, in *Anatomy*, a name given by Fabricius, and others, to the muſcle, called by Albinus *obliquus externus abdominis*. See OBLIQUI, &c.

DESCENDER, *Writ of formedon in*. See FORMEDON.

DESCENDING, ſomething that falls or moves from above, downwards.

There are aſcending and deſcending ſtars; and aſcending and deſcending degrees.

There are alſo aſcending and deſcending veins ſpringing out of the cava (ſee VEIN); and aſcending and deſcending arteries riſing out of the aorta. See ARTERY.

DESCENDING *Latitude*, in *Aſtronomy*, is the latitude of a planet in its return from the nodes to the equator.

DESCENSION, is either *right* or *oblique*.

DESCENSION, *Right, of a ſtar*, or *ſign*, is a point, or arc, of the equator, which deſcends with the ſtar, or ſign, below the horizon, in a right ſphere.

DESCENSION, *Oblique*, is a point, or arch of the equator, which deſcends at the ſame time with a ſtar, or ſign, below the horizon, in an oblique ſphere.

Deſcenſions, both right and oblique, are accounted from the firſt point of Aries, or the vernal interſection, according to the order of the ſigns; that is, from weſt to eaſt. And, as they are unequal, when it happens that they anſwer to equal arcs of the ecliptic, as, *e. gr.* to the twelve ſigns of the zodiac, it follows, that ſometimes a greater part of the equator riſes, or deſcends, with a ſign, in which caſe the ſign is ſaid to aſcend, or deſcend rightly: and ſometimes, again, a leſs part of the equator riſes, or ſets, with the ſame ſign; in which caſe, it is ſaid to aſcend and deſcend obliquely. See ASCENSION.

DESCENSION, *Refraction of the*. See REFRACTION.

DESCENSIONAL DIFFERENCE, is the difference between the right and oblique deſcenſion of the ſame ſtar, or point of the heavens, &c.

DESCENT, *diſtillation by*, in *Chemiſtry*, is a mode of diſtillation adopted in ſome inſtances, where the ſubſtance to be diſtilled is placed in a veſſel above the receiver, and heat being applied at top, the liquor drops into the receiver below, which is kept cool for that purpoſe.

DESCENT *into a ditch*, in *Fortification*, is a deep trench, or ſap, cut through the eſplanade, and under the covert-way; covered above with planks and hurdles, and loaded with earth againſt artificial fires. See MOAT.

In wet ditches the deſcent is made even to the ſurface of the water: in dry ditches, it is carried to the bottom of the moat, where traverſes are made to lodge and ſecure the miners.

DESCENT, in *Genealogy* and *Heraldry*, the order, or ſucceſſion, of deſcendants in a line, or family.

We ſay, one deſcent, two deſcents, &c. A gentleman is of perfect blood who has four deſcents of gentility, both by his father's and mother's ſide, *i. e.* whoſe great grandfather, grandfather, and father, on both ſides, were all gentlemen.

DESCENT is alſo uſed, in *Heraldry*, to expreſs the coming down of any thing from above.

Thus, a lion en deſcent is a lion with his head towards one of the baſe points, and his heels towards one of the corners of the chief; as if he were leaping from ſome high place.

DESCENT, DISCENT, or *Hereditary Succeſſion*, in *Law*, denotes the title whereby a man on the death of his anceſtor acquires his eſtate by right of repreſentation, as his heir at law; or it is the order, or manner, wherein lands and tenements are derived to any man from his anceſtors: and this is by cuſtom, ſtatute, or common law. By cuſtom, as in gavelkind or borough Engliſh; by ſtatute, as in fee-tail; and by common law, when a perſon has lands of inheritance in fee-ſimple, and dies without diſpoſing them: in which caſe the land deſcends in courſe to the eldeſt ſon and heir. The heir is, therefore, he upon whom the law caſts the eſtate immediately on the death of the anceſtor; and an eſtate, ſo deſcending to the heir, is in law called the inheritance. See HEIR and INHERITANCE.

Thus, to make his deſcent from his anceſtors, is to ſhew how, and by what particular degrees, the land in queſtion came to a perſon from his anceſtors. See CONSANGUINITY.

Deſcent, in common law, is either lineal, or collateral.

DESCENT, *Lineal*, is that conveyed down, in a right line, from the grandfather to the father, and from the father to the ſon, from the ſon to the grandſon, &c.

DESCENT, *Collateral*, is that ſpringing out of the ſide of the line, or blood; as from a man to his brother, nephew, or the like.

Judge Blackſtone has collected and illuſtrated the following rules or canons of inheritance, according to which eſtates are tranſmitted from the anceſtor to the heir. "Inheritances ſhall lineally deſcend to the iſſue of the perſon who laſt died actually ſeiſed *in infinitum;* but ſhall never lineally aſcend." The affirmative part of this rule has been almoſt univerſally adopted by all nations: but the negative part, whereby parents and all lineal anceſtors are excluded from ſucceeding to the inheritance of their offſpring, is peculiar to our laws, and thoſe of the ſame original: for, by the Jewiſh law, on failure of iſſue the father ſucceeded to the ſon, in excluſion of brethren, unleſs one of them married the widow, and raiſed up ſeed to his brother. And, by the laws of Rome, the children or lineal deſcendants were firſt preferred; and, on failure of theſe, the father and mother, or lineal aſcendants, ſucceeded together with the brethren and ſiſters; though by the law of the Twelve Tables, the mother was originally excluded, on account of her ſex. This rule was introduced into our law at the ſame time with, and in conſequence of, the feodal tenures: and though the right of ſucceſſion in the aſcending line was reſtored by Henry I. it was ſoon diſuſed; for it was laid down as an eſtabliſhed law in Glanvil's time, under Henry II. that *hereditas nunquam aſcendit;* and this maxim has been invariable ever ſince. Another rule of inheritance is, "that the male iſſue ſhall be admitted before the female." This preference of males to females is entirely agreeable to the law of ſucceſſion among the Jews, and alſo among the ſtates of Greece, or at leaſt among the Athenians; but was totally unknown to the laws of Rome, now extant, which allow brethren and ſiſters to ſucceed to equal portions of the inheritance. It was derived to us from the feodal law, and admitted on the principle, that no female could ſucceed to a proper feud, becauſe they were incapable of military ſervice. However, according to our law, though daughters are excluded by ſons, they ſucceed before any collateral re-

lations. A third rule of deſcent is, "that where there are two or more males in equal degree, the eldeſt only ſhall inherit; but the females all together." The right of primogeniture in males ſeems anciently only to have obtained among the Jews, in whoſe conſtitution the eldeſt ſon had a double portion of the inheritance. The Greeks, Romans, Britons, Saxons, and even originally the feudiſts, divided the lands equally: but when the emperors began to create honorary feuds, or titles of nobility, it was found neceſſary to make them impartible, or *feuda individua*, and deſcendible to the eldeſt ſon alone: in conſequence of which, the eldeſt male began univerſally to ſucceed to the whole of the lands in all military tenures; and in this condition the feodal conſtitution was eſtabliſhed in England by William the Conqueror. The fourth rule of deſcent is, "that the lineal deſcendants, *in infinitum*, of any perſon deceaſed, ſhall repreſent their anceſtor, or ſtand in the ſame place as the perſon himſelf would have done, had he been living." Thus the child, grand-child, or great-grand-child, male or female, of the eldeſt ſon ſucceeds before the younger ſon, and ſo *in infinitum*; and theſe repreſentatives ſhall take neither more nor leſs, but juſt ſo much as their principals would have done. As, if there be two ſiſters, Margaret and Charlotte, and Margaret dies leaving ſix daughters; and then John Stiles the father of the two ſiſters dies, without other iſſue: theſe ſix daughters ſhall take among them exactly the ſame as their mother Margaret would have done, had ſhe been living; that is, a moiety of the lands of John Stiles in coparcenary; ſo that, upon partition made, if the land be divided into 12 parts, thereof Charlotte the ſurviving ſiſter ſhall have ſix, and her ſix nieces, the daughters of Margaret, one a-piece. This is called ſucceſſion *in ſtirpes*, according to the roots; ſince all the branches inherit the ſame ſhare that their root, whom they repreſent, would have done. The Jewiſh ſucceſſion was directed in the ſame manner; but the Roman ſomewhat differed from it. This rule was indiſputably ſettled in the time of king Henry III. and has continued ever ſince. A fifth rule is, "that, on failure of lineal deſcendants, or iſſue, of the perſon laſt ſeiſed, the inheritance ſhall deſcend to his collateral relations, being of the blood of the firſt purchaſer; ſubject to the preceding rules." This rule was entirely unknown among the Jews, Greeks, and Romans; but the law of Normandy is the ſame with our's in this reſpect; both being derived from the ſame feodal origin.

Accordingly, when an eſtate hath really deſcended in a courſe of inheritance to the perſon laſt ſeiſed, the ſtrict rule of the feodal law is obſerved; and none are admitted, but the heirs of thoſe through whom the inheritance hath paſſed; for all others have demonſtrably none of the blood of the firſt purchaſer in them, and therefore ſhall never ſucceed. As, if lands come to John Stiles by deſcent from his mother Lucy Baker, no relation of his father (as ſuch) ſhall ever be his heir of theſe lands; and, *vice verſâ*, if they deſcended from his father Geoffrey Stiles, no relation of his mother (as ſuch) ſhall ever be admitted thereto; for his father's kindred have none of his mother's blood, nor have his mother's relations any ſhare of his father's blood. And ſo, if the eſtate deſcended from his father's father, George Stiles, the relations of his father's mother, Cecilia Kempe, ſhall for the ſame reaſon never be admitted, but only thoſe of his father's father. This is alſo the rule of the French law, which is derived from the ſame feodal fountain. So far, it is obſerved, as the feud is really antiquum, the law traces it back, and will not ſuffer any to inherit but the blood of thoſe anceſtors, from whom the feud was conveyed to the late proprietor. But when, through length of time, it can trace it no further; or if it be not known whether his grandfather, George Stiles, inherited it from his father, Walter Stiles, or his mother, Chriſtian Smith, or if it appear that his grandfather was the firſt grantee, and ſo took it (by the general law) as a feud of indefinite antiquity; in either of theſe caſes the law admits the deſcendants of any anceſtor of George Stiles, either paternal or maternal, to be in their due order the heirs to John Stiles of this eſtate; becauſe in the firſt caſe it is really uncertain, and in the ſecond caſe it is ſuppoſed to be uncertain, whether the grandfather derived his title from the part of his father or his mother. This then is the great and general principle, upon which the law of collateral inheritances depends; that, upon failure of iſſue in the laſt proprietor, the eſtate ſhall deſcend to the blood of the firſt purchaſer; or, that it ſhall reſult back to the heirs of the body of that anceſtor, from whom it either really has, or is ſuppoſed by fiction of law to have originally deſcended: according to the rule laid down in the Year-books, Fitzherbert, Brook and Hale, "that he who would have been heir to the father of the deceaſed" (and, of courſe, to the mother, or any other real or ſuppoſed purchaſing anceſtor) "ſhall alſo be heir to the ſon;" a maxim, that will hold univerſally, except in the caſe of a brother or ſiſter of the half-blood, which exception depends upon very ſpecial grounds.

The ſixth rule is, "that the collateral heir of the perſon laſt ſeiſed muſt be his next collateral kinſman, of the whole blood." The proximity of the collateral kinſman is reckoned according to the canonical degrees of *conſanguinity*, which ſee. Conſequently, the brother being in the firſt degree, he and his deſcendants ſhall exclude the uncle and his iſſue, who is only in the ſecond. And herein conſiſts the true reaſon of the different methods of computing the degrees of conſanguinity, in the civil law on the one hand, and in the canon and common laws on the other. The civil law regards conſanguinity principally with reſpect to ſucceſſion, and therein very naturally conſiders only the perſon deceaſed, to whom the relation is claimed: it therefore counts the degrees of kindred according to the number of perſons through whom the claim muſt be derived from him; and makes not only his great nephew but alſo his firſt couſin to be both related to him in the fourth degree; becauſe there are three perſons between him and each of them. The canon law regards conſanguinity principally with a view to prevent inceſtuous marriages, between thoſe who have a large portion of the ſame blood running in their reſpective veins; and therefore looks up to the author of that blood, or the common anceſtor, reckoning the degrees from him; ſo that the great nephew is related in the third canonical degree to the perſon propoſed, and the firſt couſin in the ſecond; the former being diſtant three degrees from the common anceſtor (the father of the *propoſitus*) and therefore deriving only one-fourth of his blood from the ſame fountain; the latter, and alſo the *propoſitus* himſelf, being each of them diſtant only two degrees from the common anceſtor (the grandfather of each) and therefore having one-half of each of theſe bloods the ſame. The common law regards conſanguinity principally with reſpect to deſcents; and having therein the ſame object in view as the civil, it may ſeem as if it ought to proceed according to the civil computation. But as it alſo reſpects the purchaſing anceſtor, from whom the eſtate was derived, it therein reſembles the canon law, and therefore counts its degrees in the ſame manner. Indeed the deſignation of perſon, in ſeeking for the next of kin, will come to exactly the ſame end (though the degrees will be differently numbered) whichever method of computation we ſuppoſe the law

law of England to uſe; ſince the right of repreſentation, of the parent by the iſſue, is allowed to prevail *in infinitum*. The iſſue or deſcendants, therefore, of John Stiles's brother are all of them in the firſt degree of kindred with reſpect to inheritances, thoſe of his uncle in the ſecond, and thoſe of his great uncle in the third; as their reſpective anceſtors, if living, would have been; and are ſeverally called to the ſucceſſion in right of ſuch their repreſentative proximity.

The former part of the preſent rule, therefore, amounts to this; that on failure of iſſue of the perſon laſt ſeiſed, the inheritance ſhall deſcend to the other ſubſiſting iſſue of his next immediate anceſtor. Thus, if John Stiles dies without iſſue, his eſtate ſhall deſcend to Francis his brother, or his repreſentatives; he being lineally deſcended from Geoffrey Stiles, John's next immediate anceſtor, or father. On failure of brethren, or ſiſters, and their iſſue, it ſhall deſcend to the uncle of John Stiles, the lineal deſcendant of his grandfather, George, and ſo on *in infinitum*. In the Jewiſh law, which in this reſpect entirely correſponds with ours, (Numb. c. 27.) the father, or other lineal anceſtor is himſelf ſaid to be the heir, though long ſince dead, as being repreſented by the perſons of his iſſue, who are held to ſucceed not in their own rights, as brethren, uncles, &c. but in right of repreſentation, as the offspring of the father, grandfather, &c. of the deceaſed. But though the common anceſtor be thus the root of the inheritance, yet with us it is not neceſſary to *name* him in making out the pedigree or deſcent. For the deſcent between two brothers is held to be an *immediate* deſcent; and therefore title may be made by one brother or his repreſentatives *to* or *through* another, without mentioning their common father. But, ſecondly, the heir need not be the neareſt kinſman abſolutely, but only *ſub modo*: that is, he muſt be the neareſt kinſman of the *whole* blood; for, if there be a much nearer kinſman of the *half* blood, a diſtant kinſman of the whole blood ſhall be admitted, and the other entirely excluded; nay, the eſtate ſhall eſcheat to the lord, ſooner than the half blood ſhall inherit. See BLOOD, *whole and half*.

The rule, together with its illuſtration, amounts to this: that in order to keep the eſtate of John Stiles as nearly as poſſible in the line of his purchaſing anceſtor, it muſt deſcend to the iſſue of the neareſt couple of anceſtors that have left deſcendants behind them; becauſe the deſcendants of one anceſtor only are not ſo likely to be in the line of that purchaſing anceſtor, as thoſe who are deſcended from both. But, as in the 2d, 3d, 4th, and every ſuperior degree every man has many couples of anceſtors, increaſing according to the diſtances in a geometrical progreſſion upwards, the deſcendants of all which reſpective couples are (repreſentatively) related to him in the ſame degree, a difficulty occurs in determining to which of theſe anceſtors we muſt firſt reſort, in order to find out deſcendants to be preferably called to the inheritance. Another qualification, therefore, is requiſite, beſides the *proximity*, and *entirety*, which is that of *dignity* or *worthineſs*, of blood. Accordingly, the ſeventh and laſt rule of deſcent is, "that in collateral inheritances the male ſtocks ſhall be preferred to the female; that is, kindred derived from the blood of the male anceſtors, however remote, ſhall be admitted before thoſe from the blood of the female, however near; unleſs where the lands have, in fact, deſcended from a female." This is warranted by the examples of the Hebrew, Athenian, and Roman laws; and alſo of the cuſtomary law of Normandy. See farther on this ſubject Blackſt. Com. vol. ii. chap. 14, paſſim.

If one dies ſeiſed of land, wherein another has a right to enter, and it deſcends to his heir; ſuch deſcent ſhall take away the other's right of entry, and put him to his action for recovery thereof. Stat. 32 Hen. VIII. c. 31. Co. Litt. 237.

DESCENT *of the Crown*. See *Right of* CROWN *and* KING.

DESCENT, *fall*, in *Mechanics*, &c. is the motion, or tendency, of a body towards the centre of the earth, either directly or obliquely: and this deſcent may be conſidered as occurring in a free or unreſiſting medium, or as impeded by ſome ſolid body, or as retarded by a denſe medium. We may therefore obſerve, 1. That if a body b deſcend freely, and in a perpendicular direction, by the force of gravity, the motive force, urging it downwards, will be equal to its whole weight, and its quantity of matter being alſo b, the accelerative force will be $\frac{b}{b}$ or 1.

2. If, whilſt the body b is deſcending, it is made to deſcend obliquely along an inclined plane, the ſine of whoſe angle of inclination to the horizon is s, the radius being 1, the motive force urging the body down the plane will be $b\,s$, and therefore the accelerative force will be $\frac{b\,s}{b}$ or s, leſs than that in the former caſe in the proportion of s to 1.

3. A body cannot deſcend in a denſe or reſiſting medium, unleſs it can divide and ſeparate the medium; which it cannot do, unleſs it be ſpecifically heavier than the medium. For ſince bodies cannot penetrate each other, one muſt give way before the other can move: and again, though a medium, *e. gr.* water, be diviſible, yet if it be ſpecifically heavier than another, *e. gr.* wood, it is only heavier as it contains more particles of matter in the ſame bulk, all which have an impulſe downwards; and, conſequently, in water there is a greater impulſe than in the ſame bulk of wood.

4. The deſcending body loſes as much of its weight as is the weight of the medium, with the force of its coheſion, and the oppoſing force of the particles againſt which it impinges, which laſt produces a greater or leſs reſiſtance, according to the velocity of the motion. And, therefore, a body ſpecifically heavier deſcends in a fluid medium ſpecifically lighter (*e. gr.* the air) with a force equal to the exceſs of the weight of the body above an equal bulk of the medium: for a body only deſcends in a medium with the force remaining, after a part has been ſpent in overcoming the reſiſtance of the medium; and this reſiſtance is equal to the weight of an equal bulk of the medium; conſequently, the body only falls with the exceſs of its weight above that of an equal bulk of the medium. In this caſe, the weight of the body being b, and that of an equal bulk of the medium being m, the motive force urging the body to deſcend will be only $b - m$.

Hence, the power that ſuſtains a body in a ſpecifically lighter medium, is equal to the exceſs of the abſolute weight of the body above an equal bulk of the medium. Thus $47\frac{1}{3}$ pounds of copper in water loſe $5\frac{1}{3}$ of their weight. A power, therefore, of 42 pounds is able to ſuſtain them.

5. If two bodies have the ſame ſpecific gravity, the leſs the bulk of the deſcending body is, the more of its gravity does it loſe, and the ſlower does it deſcend, in the ſame medium. For, though the proportion of the ſpecific gravity of the body to that of the fluid be ſtill the ſame in a greater or leſſer bulk, yet the leſs the body, the greater is the ſurface, in proportion to the maſs; and the larger the ſurface, the greater is the reſiſtance of the parts of the fluid.

6. If the ſpecific gravities of two bodies be different, that which has the greateſt ſpecific gravity will deſcend with greater velocity in the air or other reſiſting medium, than

the other. Thus a ball of lead deſcends ſwifter than wood or cork, becauſe it loſes leſs of its weight, though in vacuo they both fall with equal velocity.

The cauſe of this deſcent, or tendency downwards, has been greatly controverted. There are two oppoſite hypotheſes advanced; the one holding it to proceed from an internal, and the other from an external principle: the firſt maintained by the PERIPATETICS and EPICUREANS, and by the NEWTONIANS; and the latter by the CARTESIANS and GASSENDISTS. See ACCELERATION.

Laws of the DESCENT *of Bodies.* 1. Heavy bodies, in an unreſiſting medium, fall with an uniformly accelerated motion. See the *laws of uniformly accelerated motion*, under the articles ACCELERATION and MOTION. 2. The ſpace deſcribed by a body, urged by an uniform gravity, is ſubduple of that which it would deſcribe in the ſame time by the velocity laſt acquired and uniformly continued.

Galileo, who firſt diſcovered the *law of the deſcent* of heavy bodies by reaſoning, afterwards confirmed the ſame by experiments, the reſult of which, repeated often both by him and ſince his time, by Grimaldi, Riccioli, Huygens, Newton, and many others, was, 3. That the ſpaces of deſcent were as the ſquares of the times, or the ſquares of the velocities. See ACCELERATION.

Dr. Deſaguliers tried the effect of falling bodies by cauſing a leaden ball to fall from the inner cupola of St. Paul's church, whoſe altitude from the ground is 272 feet. Through this ſpace the ball deſcended in $4\frac{1}{2}$ ſeconds; during which time it ſhould, according to the theory, have deſcended through 325.6 feet, making a difference of about one-fifth of the actual deſcent between the experiment and the theory. This difference he ſhews to have ariſen principally from the reſiſtance of the air. To remedy the defects of theſe and ſimilar experiments, Mr. Atwood contrived his apparatus, for an account of which, ſee MOTION.

Grimaldi and Riccioli made experiments to the ſame effect, though in a different manner, by letting fall a number of balls, weighing eight ounces a-piece, from the tops of ſeveral towers, and meaſuring the times of falling by a pendulum. Riccioli. Almag. Nov. tom. i. lib. ii. cap. 21. prop. 4. Theſe experiments are exhibited in the following table.

Vibrations of the Pendulum.	Time.	Space at the end of the Time.	Space deſcended each Time.
	″ ‴	Rom. Foot.	Rom. Foot.
5	0 50	10	10
10	1 40	40	30
15	2 30	90	50
20	3 20	160	70
25	4 10	250	90
6	1 0	15	15
12	2 0	60	45
18	3 0	135	75
24	4 0	240	105

By ſuch and ſimilar experiments the ſpace deſcended by a heavy body, in a given time, has been aſcertained; and hence have been deduced theorems for eſtimating the times, velocities, and alſo the ſpaces deſcended, as far as they depend on an uniform force of gravity. From many accurate experiments made in England, it has been found that a heavy body falling freely, deſcends through $16\frac{1}{12}$ feet, in the firſt ſecond of time; and therefore the velocity gained at the end of one ſecond is $32\frac{1}{6}$ feet *per* ſecond. Hence we may infer that the velocity gained in any other time t is $32\frac{1}{6}\,t$, and that the ſpace deſcended is $16\frac{1}{12}\,t^2$.

Let v denote the velocity, and s the ſpace correſponding to the time t, and put $g = 16\frac{1}{12}$; then we ſhall have

$$v = 2gt = 2\sqrt{gs} = \frac{2s}{t}.$$

$$s = gt^2 = \frac{v^2}{4g} = \tfrac{1}{2}tv.$$

$$t = \frac{v}{2g} = \sqrt{\frac{s}{g}} = \frac{2s}{v}.$$

See ACCELERATION.

The ſpace deſcribed by a deſcending body in a ſecond of time has been alſo aſcertained by experiments with pendulums. In the latitude of London the length of a pendulum vibrating ſeconds is $39\frac{1}{8}$ inches; and ſince the circumference of a circle is to its diameter as the time of one vibration of any pendulum is to the time in which a heavy body will fall through half the length of the pendulum, we ſhall have $3.1416 : 1 :: 1 : \frac{1}{3.1416}$, which is the time of deſcending through $19\frac{9}{16}$ inches, or half the length of the pendulum; and, ſpaces being as the ſquares of the times, $\left(\frac{1}{3.1416}\right)^2 : 1^2 :: 19\frac{9}{16} : 193$ inches, or 16 feet 1 inch, which is the ſpace through which a heavy body will deſcend in one ſecond, as before. See PENDULUM.

4. The time wherein a body falls from a given height being given, to determine the ſpaces it fell in the ſeveral parts of that time.

Suppoſe the given altitude $= a$, the time $= t$, and the ſpace it fell in one part of time x: then

$$\frac{1 : x = t^2 : a}{t^2 x = a}$$

$$x = \frac{a}{t^2}.$$

Therefore the ſpace paſſed over in the firſt part of time is $\frac{a}{t^2}$: conſequently that paſſed over in the ſecond time $= \frac{3a}{t^2}$; that in the third $= \frac{5a}{t^2}$, &c. See ACCELERATION, *art.* 3.

5. The time wherein a body falls through a given ſpace being given; to determine the time wherein it will fall through any other given ſpace, in the ſame medium.

Since the ſpaces are as the ſquare of the times, to the ſpace which the body falls in the given time, the ſpace in the queſtion, and the ſquare of the given time, find a fourth proportional, which will be the ſquare of the time ſought. The ſquare root, therefore, being extracted therefrom, the problem is ſolved.

6. The ſpace a body falls in a given time being given; to determine the ſpace through which it will fall in any other given time.

To the ſquare of the time wherein the body falls through the given ſpace, the ſquare of the time wherein it ſhould fall through the ſpace required, and the given ſpace, ſeek a fourth proportional; this will be the ſpace required.

7. For any other conſtant force, inſtead of the perpendicular free deſcent by gravity, find the ſpace deſcended in one ſecond by a body urged by that force, and ſubſtitute that inſtead of $16\frac{1}{12}$ for the value of g in the preceding formulæ: or, if the proportion of this force to that of gravity be known, let the value of g be altered in the ſame proportion, and the ſame

ſame formulæ will hold good. Thus alſo, if the deſcent be on an inclined plane, making, *e. g.* an angle of 30° with the horizon; then, the force of deſcent upon the plane being always as the ſine of the angle it makes with the horizon; it will, in the preſent caſe, be as the ſine of 30°, that is, half the radius; and therefore in this caſe the value of *g* will be but half the former, $8\frac{1}{12}$, in the preceding formulæ. The ſame adaptation may be applied to any conſtant forces whatever.

8. The time of the oblique deſcent down any chord of a circle is equal to the perpendicular deſcent through the diameter of the circle.

9. The deſcents or vibrations through all arcs of the ſame cycloid, whether great or ſmall, are equal.

10. The deſcents, or vibrations, through unequal arcs of circles are unequal; the times being greater in the greater arcs, and leſs in the leſs.

For the Laws of DESCENT *by variable forces*, ſee FORCES.

DESCENT, *Line of ſwifteſt*, is that which a body, falling by the action of gravity, deſcribes in the ſhorteſt time from one given point to another; which is proved by geometricians to be the *cycloid*; which ſee.

DESCENT *of the Uterus*, in *Midwifery*, ſee *Bearing down of the* UTERUS. &c.

DESCHEL, in *Geography*, a town of Brabant; 13 miles S. of Herentals.

DESCHKIN, a town of Ruſſia, in the government of Orel; 24 miles N. of Orel, and 484 S.S.E. of Peterſburg.

DESCHNAY, a town of Bohemia, in the circle of Konigingratz; 21 miles E N.E. of Konigingratz.

DESCHNO, a town of Bohemia, in the circle of Boleſlaw; 4 miles W. of Aycha.

DESCRIBENT, is a term in *Geometry*, expreſſing ſome line or ſurface, which by its motion produces a plane figure, or a ſolid.

DESCRIPTON, in *Logic*, an imperfect, or inaccurate definition of a thing, giving a ſort of knowledge thereof from ſome accidents and circumſtances peculiar to it, which determine it enough to give an idea that may diſtinguiſh it from other things; but without explaining its nature or eſſence.

Grammarians content themſelves with deſcriptions: philoſophers require definitions of things. See DEFINITION. A deſcription is an enumeration of divers attributes of a thing, moſt of which are only accidental: as, when a perſon is deſcribed by his deeds, his ſayings, his writings, his honours, &c. A deſcription, as to its outward appearance, reſembles a definition, and is even convertible with the thing deſcribed; but does not explain it. For, inſtead of bringing ſeveral things eſſential to the thing deſcribed, it only brings a number of accidents belonging to it. A deſcription, therefore, is no proper anſwer to the queſtion, *quid eſt*, what is he? but to that, *quis eſt*, who is he?

Deſcriptions, in effect, are principally uſed for ſingulars, or individuals; for things of the ſame ſpecies do not differ in eſſence, but only as to *hic* and *ille*, which difference contains nothing very notable, or diſtinguiſhable. But individuals of the ſame kind differ much in accidents; *e. gr.* George is a king, and William a citizen; Charles is a male, and Anne a female; Henry is wiſe, and John a blockhead, &c. Thus, a deſcription is an accumulation of accidents, whereby things are notably diſtinguiſhed from each other, though they ſcarce differ at all in eſſence.

Some authors call a deſcription a quaſi-definition, as, body is a thing diviſible, moveable, ſolid, extended, &c., which only falls ſhort of a definition in this, that, inſtead of the form or eſſence of a thing, it gives one or more properties ariſing from the form or eſſence.

DESCRIPTION, in *Geometry*. To deſcribe a circle, ellipſis, parabola, &c., is to conſtruct or form thoſe figures, with rules, compaſſes, &c.

DESCRIPTION, in *Law*. In deeds and grants there muſt be a certain deſcription of the lands granted, of the places where they lie, and of the perſons to whom granted, &c., in order to make them good. But wills are more favoured than grants as to theſe deſcriptions; and a wrong deſcription of the perſon will not make a demiſe void, if there be likewiſe a ſufficient certainty what perſon was intended by the teſtator. (1 Nelſ. Abr. 64.)

DESCRIPTION, in *Poetry and Rhetoric*, is a figure which, by the aid of imagery and argument, exhibits ſuch a ſtrong and lively repreſentation of a ſubject, as gives a diſtinct view and ſatisfactory notion of it to the reader or hearer; and whilſt it convinces the mind, it moves and ſways the paſſions. This figure is principally uſed by poets, not only with a deſign to move the paſſions, but to pleaſe the fancy. Hiſtorians alſo deſcribe things, places, and perſons; and orators produce the greateſt effect by deſcription. In what a beautiful light has Cicero (Pro Arch. c. 7.) exhibited the polite arts and ſciences when he deſcribes their effects, and repreſents the benefit and pleaſure which they afford to the mind! "Other ſtudies neither ſuit with all times, nor all ages, nor all places, but theſe improve youth, delight old age, adorn proſperity, afford a refuge and ſolace in adverſity; pleaſe at home, are no hinderance abroad, ſleep, travel, and retire with us." Quintilian (Inſt. Orat. l. viii. c. 3.) has painted, by deſcription, the calamities of a city taken by ſtorm, in the brighteſt and ſtrongeſt colours: "Flames ſpreading themſelves over the houſes and temples, the cracking of falling buildings, and a confuſed noiſe from a variety of cries and ſhouts; ſome running they knew not where, others in the laſt embraces of their friends, the ſhrieks of children, women, and old men unhappily reſerved to ſuch diſtreſs; the plundering of all places civil and ſacred, the hurry and confuſion in carrying off the booty, captives driven before their victors, mothers endeavouring to guard their infants, and quarrels among the conquerors, where the plunder is largeſt." Juſtin alſo (lib. xxix. c. 3.) gives us a fine inſtance of deſcription, in a ſpeech of king Philip V. of Macedon, in which he repreſents the neceſſity of falling upon the Romans, who at that time were engaged in a war with Hannibal. "I behold," ſays he, "a cloud of a moſt dreadful and bloody war riſing in Italy. I ſee a ſtorm of thunder and lightning from the weſt, which will overſpread all places with a vaſt ſhower of blood, into whatever country the tempeſt of victory ſhall drive it. Greece has undergone many violent ſhocks in the Perſian, Gallic, and Macedonian wars; but theſe would all be found unworthy of regard, if the armies now engaged in Italy ſhould march out of that country. I view the terrible and cruel wars, which involve thoſe nations through the courage of their forces, and ſkill of their generals. This rage and fury cannot ceaſe by the deſtruction of one party, without the ruin of their neighbours. Indeed Macedon has leſs reaſon to dread the ſavage conquerors than Greece; becauſe more prepared, and better able to defend itſelf; but I am ſenſible thoſe who attack each other ſo impetuouſly will not confine their victories within thoſe bounds; and that it will be our lot to engage the conquerors."

A though deſcriptive poetry does not denote any one particular ſpecies or form of compoſition, and deſcription is generally introduced as an embelliſhment rather than made the ſubject of a regular

a regular work; it nevertheleſs enters into every ſpecies of poetical compoſition, paſtoral, lyric, didactic, epic and dramatic, and in each of them poſſeſſes a very conſiderable place. Deſcription, ſays Dr. Blair, (Lect. vol. iii. p. 158.) is the great teſt of a poet's imagination; and always diſtinguiſhes an original from a ſecond-rate genius. A true poet makes us imagine that we ſee the object which he deſcribes before our eyes; he catches the diſtinguiſhing features; he gives it the colours of life and reality; he places it in ſuch a light that a painter could copy after him. This happy talent is chiefly owing to a ſtrong imagination, which firſt receives a lively impreſſion of the object; and then, by employing a proper ſelection of circumſtances in deſcribing it, tranſmits that impreſſion in its full force to the imagination of others. In this ſelection of circumſtances lies the great art of pictureſque deſcription. In the firſt place they ought not to be vulgar, and common ones, ſuch as are apt to paſs by without remark; but as much as poſſible, new and original, which may catch the fancy and draw attention. In the next place, they ought to be ſuch as particularize the object deſcribed, and mark it ſtrongly. No deſcription that reſts in generals can be good; for we can conceive nothing clearly in the abſtract. In the third place, all the circumſtances employed ought to be uniform; that is, when deſcribing a great object, every circumſtance brought into view ſhould tend to aggrandize; or, when deſcribing a gay and pleaſant one, ſhould tend to beautify, that by this means, the impreſſion may reſt upon the imagination complete and entire; and laſtly, the circumſtances in deſcription ſhould be expreſſed with conciſeneſs, and with ſimplicity; for when either too much exaggerated, or too long dwelt upon and extended, they never fail to enfeeble the impreſſion that is deſigned to be made. Of all deſcriptive compoſitions, the largeſt and fulleſt, ſays Dr. Blair, with which he is acquainted, is Mr. Thomſon's Seaſons; a work that poſſeſſes very uncommon merit. Thomſon is a ſtrong and a beautiful deſcriber; for he had a feeling heart and a warm imagination. From him we might ſelect ſeveral inſtances of moſt beautiful deſcription; as, the ſhower in ſpring, the morning in ſummer, and the man periſhing in ſnow in winter. In a paſſage of another kind we perceive the power which a ſingle well-choſen circumſtance has in heightening a deſcription. In his Summer, relating the effects of heat in the torrid zone, he is led to take notice of the peſtilence that deſtroyed the Engliſh fleet at Carthagena, under admiral Vernon; when he has the following lines:

" ——————— You, gallant Vernon, ſaw
The miſerable ſcene; you pitying ſaw
To infant weakneſs ſunk the warrior's arm;
Saw the deep racking pang; the ghaſtly form;
The lip pale quiv'ring; and the beamleſs eye
No more with ardour bright; you heard the groans
Of agonizing ſhips from ſhore to ſhore:
Heard nightly plunged, amid the ſullen waves,
The frequent corſe.——" l. 1050.

Mr. Parnell's tale of the Hermit is conſpicuous throughout the whole of it, for beautiful deſcriptive narration. But of all the Engliſh poems in the deſcriptive ſtyle, the richeſt and moſt remarkable are Milton's Allegro and Penſeroſo. The collection of gay images on the one hand, and of melancholy ideas on the other, exhibited in theſe two ſmall, but inimitably fine poems, are as exquiſite as can be conceived. The following paſſage is ſelected by Dr. Blair from the Penſeroſo;

" ——— I walk unſeen
On the dry, ſmooth-ſhaven green,
To behold the wandering moon,
Riding near her higheſt noon,
Like one that had been led aſtray
Through the heaven's wide pathleſs way,
And oft, as if her head ſhe bow'd,
Stooping through a fleecy cloud,
Oft, on a plat of riſing ground,
I hear the far-off curfew ſound,
Over ſome wide watered ſhore,
Swinging ſlow with ſolemn roar:
Or, if the air will not permit,
Some ſtill removed place will fit,
Where glowing embers through the room
Teach light to counterfeit a gloom:
Far from all reſort of mirth,
Save the cricket on the hearth,
Or the bellman's drowſy charm,
To bliſs the doors from nightly harm:
Or let my lamp, at midnight hour,
Be ſeen in ſome high lonely tower,
Where I may outwatch the Bear
With thrice great Hermes, or unſphere
The ſpirit of Plato to unfold
What worlds, or what vaſt regions hold
Th' immortal mind, that hath forſook
Her manſion in this fleſhly nook:
And of thoſe dæmons that are found
In fire, air, flood, or under-ground."

Here are, as he obſerves, no unmeaning general expreſſions; all is particular, all is pictureſque; nothing forced or exaggerated; but a ſimple ſtyle, and a collection of ſtrong expreſſive images, which are all of one claſs, and recal a number of ſimilar ideas of the melancholy kind; particularly the walk by moonlight; the ſound of the curfew-bell heard diſtant; the dying embers in the chamber; the bellman's call; and the lamp ſeen at midnight, in the high lonely tower. The poet's manner is alſo admirably conciſe; and this manner, in deſcribing ſolemn or great objects, is almoſt always proper. It farther deſerves attention, that in deſcribing inanimate natural objects, the poet, in order to enliven his deſcription, ought always to mix living beings with them. It is a great beauty in Milton's Allegro, that it is all alive, and full of perſons. Every thing in deſcription ſhould be as marked and particular as poſſible, in order to imprint on the mind a diſtinct and complete image. Moſt of the ancient writers were apprized of the advantage which this circumſtance gives to deſcription. Thus, in the beautiful paſtoral compoſition, the Song of Solomon, the images are commonly particularized by the objects to which they allude. (See ch. iv. 8.) Both Homer and Virgil were remarkable for the talent of poetical deſcription. All Homer's battles, Virgil's deſcription of the burning and ſacking of Troy, in the ſecond Æneid, and Milton's account both of paradiſe, and of the infernal regions, furniſh many inſtances of poetical deſcription.

Much of the beauty of deſcriptive poetry depends on a right choice of epithets. In this caſe every epithet ſhould either add a new idea to the word which it qualifies, or at leaſt ſerve to raiſe and heighten its known ſignification. So in Milton:

" —— Who ſhall tempt with wand'ring feet
The dark, unbottom'd, infinite abyſs,
And through the palpable obſcure, find out
His uncouth way? or ſpread his airy flight,
Upborn with indefatigable wings,
Over the vaſt abrupt?" b. ii.

Sometimes it is in the power of a poet of genius, by one well-choſen epithet, to accompliſh a deſcription, and by means of a ſingle word, to paint a whole ſcene to the fancy. The following lines of Milton's Lycidas manifeſt this effect of an epithet:

" Where were ye, nymphs, when the remorſeleſs deep
Cloſ'd o'er the head of your lov'd Lycidas?
For neither were ye playing on the ſteep,
Where your old bards, the famous Druids, lie,
Nor on the ſhaggy top of Mona high,
Nor yet where Deva ſpreads her wizard ſtream."

Horace and Virgil have alſo occaſionally employed epithets with great beauty and propriety.

Upon the whole, the deſcriptive talents of an author may be reaſonably diſtruſted, when we find him laborious and turgid, amaſſing common-place epithets, and general expreſſions, to work up a high conception of ſome object, of which, after all, we can form but an indiſtinct idea. The beſt deſcribers are ſimple and conciſe; they ſet before us ſuch features of an object, as, on the firſt view, ſtrike and warm the fancy; they give us ideas which a ſtatuary or a painter could lay hold of, and work after them; which is one of the ſtrongeſt and moſt deciſive trials of the real merit of Deſcription.

The deſcription of a perſon is called a character.

For the difference between deſcription and imitation; ſee IMITATION.

DESEADA. See LA DESIRADE.

DESEADA, *Cape*, the ſouthern point of the ſtraits of Magellan in S. America, at the entrance of the South ſea. S. lat 53°. W. long. 74° 40'.

DESEADEN, a town of Perſia, in the province of Segeſtan; 30 miles S. S. E. of Kin.

DESENIK, a town of Hungary; 10 miles S. of Levens.

DESENZANO, or DISSENZANO, a town of Italy, in the Breſſan; celebrated for its wines; 15 miles E. of Breſcia.

DESERT, or DESART, a wild, uncultivated, uninhabited place or country: as the deſerts of Libya, of the Thebaid, &c. Geographers uſe the word in the general for all countries little, or not at all, inhabited. In Scripture, we find ſeveral places in the Holy Land, or places adjoining thereto, called deſerts, which were not abſolutely barren or unfruitful, but ſuch as were rarely ſown or cultivated; and though they yielded no crops of corn or fruit, they nevertheleſs afforded herbage for the graziers of cattle, with fountains or rills of water, though more ſparingly interſperſed than in other places. The wilderneſs or deſert, which was the ſcene of our Saviour's temptation, with ſeveral others mentioned in Scripture, was of this nature and quality. Many of theſe deſerts contained cities and villages, rich and well peopled; and, indeed, almoſt every city had ſome deſert according to the Scripture idiom, belonging to it for paſture: ſo that the word meant no more than a land, or tract, that bore neither corn, wine, nor oil, but was left to the ſpontaneous production of nature. Reland (Paleſt. l. i. p. 375.) hath fully ſhewn that the Hebrew word מדבר *midbar*, which the Greeks rendered ἔρημος, and the Latins *deſertum* and *ſolitudo*, bear no analogy to each other; and that the former was appropriated to the feeding of flocks, whilſt the cultivated lands were ſtyled plains and vallies, and thoſe that excelled in fertility, were diſtinguiſhed by ſome proper epithets, or even names of that import. The Scripture ſpeaks of the beauty of the deſert. Pſ. lxiv. 13. Jer. ix. 10. Joel. i. 20.

The deſert or wilderneſs, abſolutely ſo called, is that part of Arabia on the ſouth of the Holy Land, wherein the Iſraelites wandered, from the time of their evacuating Egypt to their entry into the Promiſed Land. The deſert of Beerſheba was that part of the deſert juſt mentioned, which bordered on the Holy Land, running towards the Mediterranean. The deſert of Idumæa is Idumæa itſelf, a barren mountainous country. The deſert of Shur lay north of the Red ſea; in this wilderneſs Hagar wandered; and Iſrael came hither after having paſſed the Red ſea. The deſert of Paran was ſituated in Arabia Petræa, near the city of Paran; and here was the habitation of Iſhmael (Gen. xxi. 11.) There were two deſerts of Sin; one written with a *ſamech* סין, (Exod. xvi. 1.) which lay between Elim and mount Sinai, and another written with a *tzade*, צין, (Exod. xix. 2.) near Kadeſh-Barnea. The deſert of Sinai was adjacent to mount Sinai. The deſert of Arnon was ſo called from the brook Arnon which ran through the land of Gilead, on the frontiers of Arabia Deſerta. The deſert of Ziph was the place of David's retreat from Saul (ſee ZIPH). The deſert of Maon (1 Kings, xxiii. 24.) lay in Arabia Petræa, at the extremity of Judah. The deſert of Kadeſh was ſituate above Kadeſh-Barnea, in the ſouth of Judah, and in Arabia Petræa. The deſert of Palmyra lay between the Euphrates and the rivers Orontes and Chryſorrhoas. The deſert of Egypt (Ezek. xx. 36.) ſeems to denote the deſert in which the Hebrews ſojourned after quitting Egypt. The deſert of Judæa or Judah was the ſcene of the preaching of John the Baptiſt (Matt. iii. 1.) This contained no leſs than ſix cities, beſides villages; *viz.* Bethabarah, Middin, Secanah, Nibſhan, the city of Salt, and that of Engedi. The deſerts of Tekoah, Bezer, Bozrah, or Boſor, Gibeon or Gibea, Horeb, Moab, and others of leſs note, were denominated from the cities to which they belonged; and were ſo many dry, uncultivated, and in general mountainous places like our downs, &c. where there are few or no habitations or inhabitants; whence the Hebrews call them by antiphraſis מדבר, which properly ſignifies human word, or ſpeech, becauſe there is none heard there.

One of the moſt ſtriking features of Africa is its immenſe deſerts, which pervade many parts of that continent, and may poſſibly comprize one-half of its whole extent. The chief of theſe is that called "the Deſert," *Sahara* or *Zaara*; which ſee. The ſandy deſerts of Arabia have in every period of time preſented to the view of the obſerver and to the arrangements of the geographers objects, highly worthy of attention. From Oman to Mecca, the greater part of Neged is one prodigious deſert, interrupted towards the frontiers of Hejaz and Yemen by Kerjé, containing the diſtrict of Surſa, and ſome fertile ſpots and towns, indicated by Niebuhr. The N. W. part of Neged preſents almoſt a continued deſert, a prolongation of the other, with an oaſis, and on the W. of Lachſa, including Jabrin, and ſome other places, mentioned by that author. In this deſert there are alſo the oaſis of mount Sehamer; and probably ſeveral others. Perſia is divided by its mountains and deſerts, for an account of which, ſee PERSIA.

DESERT *Iſlands*, in *Geography*, a denomination given to a number of African iſlands, that lie E. of Madagaſcar, and from the 5th to the 40th degree of latitude; which it is needleſs to enumerate, as neither their names nor ſituation are perfectly aſcertained.

DESERT *Iſland*, *Mount*, an American iſland, which lies on the coaſt of the diſtrict of Maine, Maſſachuſetts, containing about 200 families, and divided into two different ſettlements, about 15 miles apart.

DESERTER, in *Military Language*, a perſon of whatever rank, whether commiſſioned, or non-commiſſioned, who having entered into the ſervice of his country, by land or by ſea, abſents himſelf from his poſt without permiſſion, and neglects to perform the ſeveral duties of his ſituation. It is, however,

neceſſary that the party ſhould have received pay, or ſome allowance in money, raiment, accoutrements, or proviſions. The fact muſt alſo be decidedly proved by ſome overt act; ſuch as abſconding, going over to the enemy, ſecreting when duty, however trivial, required the party's preſence, with the known intention to quit the ſervice clandeſtinely. But if a ſoldier be abſent for many days, or weeks, through illneſs; or if he be intoxicated, or confined for debt, ſo that he could not attend at quarters, ſuch phyſical inabilities would exempt him from the imputation of deſertion; though in caſe of inebriety he would receive the puniſhment incurred by that treſpaſs.

Officers who deſert are, in almoſt every ſervice, executed: ſuch ſeverity is undoubtedly very proper, on account of the ill effects inſeparable from the bad example of ſuperiors. The Britiſh army and navy however can happily boaſt an exemption from this crime; which we could wiſh were equally unknown among the ſubordinate ranks, wherein it is, indeed, too commonly practiſed.

Our military code inflicts "death, or ſuch other puniſhment as may be adjudged by a general court-martial," on deſerters; whereby a proper diſcretionary power is left for the exerciſe of lenity in ſuch caſes as may appear leſs heinous, or where circumſtances may be favourable to the accuſed; although the crime might have been ſubſtantiated. Thus we certainly ſhould make a wide diſtinction between the ſoldier, who, in conſequence of bribery, or of diſcontent, either went over to the enemy, or urged others to do ſo, or who carried away his horſe, arms, &c.; and the irreſolute individual who being emaciated by ſickneſs, hunger, fatigue, or being under the influence of a large family, quitted his colours, without any adverſe intention. Repetition of the crime, and the nefarious practice of receiving bounties in ſeveral different regiments, or ſhips, aſſuredly cannot find any honeſt advocate.

Such is the deteſtation in which deſerters are held in every part of the world, that we invariably find them ſentenced to death. Even the uncivilized nations of America and Africa conform to this principle; and, probably annexing the ſtain of treachery to the treſpaſs, not unfrequently conſign all the family of the deſerter, with himſelf, to the flames!

Not only the officers, ſoldiers, &c. ſerving in regiments of the line, and other regular bodies, are ſubject to puniſhment when they abſent themſelves from their colours, but all perſons who are allowed, or are called upon by goverment, to embody, or to bear arms in the ſervice of the ſtate, are equally amenable to the military code; and, whatever their rank, or ſituation in private life, to all the penalties incurred by inattention to, or diſobedience of, martial law.

However expedient the moſt ſtrict regulations may be in time of actual war, yet in times of profound peace, a little relaxation of military rigor would not, one ſhould hope, ſays judge Blackſtone, be productive of much inconvenience. Upon this principle, though by our ſtanding laws (ſtat. 18 Hen. VI. c. 19. 2 and 3 Edw. VI. c. 2.), ſtill remaining in force, though not attended to, deſertion in time of war is made felony, without benefit of clergy, and the offence is triable by a jury and before juſtices at the common law; yet by our militia laws, a much lighter puniſhment is inflicted for deſertion in time of peace. So, by the Roman law alſo, deſertion in time of war was puniſhed with death, but more mildly in time of tranquillity. But our mutiny act makes no ſuch diſtinction; for deſertion, &c. is puniſhable with death itielf, if a court-martial ſhall think proper. See COURT MARTIAL and MUTINY ACT.

For the manner of puniſhing deſerters among the ancients, ſee TRANSFUGA.

DE'SERTINES, in *Geography*, a ſmall town of France, in the department of Mayenne; 15 miles north-weſt of the town of Mayenne.

DESESPOIR, or DESPAIR, *Cape*, a cape of America, on the northern ſide of Chaleur bay, about three leagues weſt-ſouth-weſt of Bonaventure iſland. Here is a large cod-fiſhery.

DESHABILLE, compounded of the privative *de*, and *s'habiller*, to *dreſs one's ſelf*, a French term, naturalized of late. It properly ſignifies a night-gown, and other neceſſaries, made uſe of in dreſſing or undreſſing.

DESHACHE', Fr. from *de* and *hacher*, *to cut*, in *Heraldry*, is when a beaſt has its limbs ſeparated from the body, ſo as they ſtill remain on the eſcutcheon, with only a ſmall ſeparation from their natural places.

DESICCATION, in *Chemiſtry*, is the act of reducing any ſubſtance to perfect dryneſs, and is an operation the accuracy of which is of very great importance, as the eſtimation of weights and quantities is materially affected by it. Some of the heats uſually employed by chemiſts for deſiccation may be here mentioned.

1. Very gentle heat.—Such as, for example, that of an inhabited chamber, or the open air in ſummer. Many ſubſtances are decompoſed and altered at a higher heat, and ſome of the more powerful fulminating compounds explode. The range of this heat may be taken at about from 60° to 70°.

2. Solar or moderate artificial heat.—The heat of the ſun's rays, when not concentrated by artificial means, ſeldom exceeds 120°, and is often reſorted to by chemiſts. The temperature, which would be denominated *moderate artificial heat*, may be taken at about 100° to 120°, and is often employed for drying many vegetable and decompoſable preparations. Neither fermentation nor putrefaction go on at this temperature.

3. It is often neceſſary to fix ſome maximum of deſiccation between 120° and 212° to fulfill particular purpoſes; ſuch as, for example, to avoid the coagulation of albumen, or to avoid the evaporation of any portion of the ſubſtance itſelf which is to be dried. Thus, for example, muriate of magneſia parts with a portion of its acid, as well as its water, at a heat above 180°, and the ſuccinats are partially decompoſed from the like cauſe. In ſuch caſes, therefore, the point of deſiccation ſhould be ſteadily kept up, which may often be conveniently effected by a ſlow-burning lamp, and a cloſed apparatus.

4. The heat of boiling water, or the water-bath heat, as it is uſually termed.—This temperature is, on the whole, that which is moſt frequently uſed by chemiſts, being conveniently applied, and if properly managed, is very ſteady and uniform. The heat of boiling water itſelf is 212°, but any ſubſtance contained in a veſſel only immerſed in boiling water, or its vapour, falls ſhort of this temperature a few degrees. However, by ſaturating the water with ſalt, its boiling point is ſo much raiſed, that it is able to impart a heat of full 212° to any body immerſed in it. It is generally ſuppoſed that as water is totally evaporable, the boiling point of water affords heat enough to expel this fluid from any ſubſtance with which it may be united; but this is not correct, for all the ſalts that have any affinity with this fluid will retain a portion of it after any deſiccation at 212°, however long continued, and the more obſtinately, as appears, in proportion to the force of this affinity. So that moſt ſaline bodies, and even earths and metallic oxyds, after being dried at 212°, will loſe a little more water in a higher heat. In general it requires from half an hour to an

hour to expel from even a ſmall maſs of ſubſtance all the water which it will part with at this heat.

5. The heat of an Argand lamp may be conſidered as a convenient and tolerably uniform mean between the temperature of boiling water, and a low red heat. It may be reſorted to on very many occaſions with great advantage, as there are numerous ſaline earths and metallic ſubſtances that only part with water at this temperature, and none of their other conſtituent parts. The deſiccation produced in this way is uſually very compleat and conveniently rapid, eſpecially when the ſubſtance is contained in a cup of platina or other metal.

Laſtly, we may mention the heat of low redneſs which is juſt viſible by day-light, and this is in moſt caſes the utmoſt heat employed for mere deſiccation; though there are ſome ſubſtances which will retain water till they have been expoſed to a ſtrong red-heat.

DESICCATION, in *Geology*, is a term that has been uſed by geologiſts to expreſs the drying or hardening of the ſtrata of the earth, particularly of ſuch ſtrata as preſent many veins, rifts, and caverns, *e. g.* the mountain lime-ſtone in Derbyſhire: whoſe veins of ore preſent ſtrong reaſons for ſuppoſing them to have been formed by the ſhrinking and cracking of the rock in which the mines are ſunk, at a period long prior to the violent heavings and rupture which the ſtrata there have undergone; becauſe the inſtances are numerous, of a fiſſure traverſing a vein that was previouſly quite filled with ſpar and ore, and the ſucceſſive heavings of the ſtrata, noticed under our article COLLIERY, have ground the two ſurfaces into furrows, and covered them with a poliſhed coating of galena, called *ſlickenſide*, which ſee. Fiſſures alſo frequently croſs and interſect the veins, and have introduced rolled pebbles and other extraneous and alluvial matters to great depths in the earth.

DESIDERATUM, from *deſidero, I deſire*, is uſed to ſignify deſirable improvements in any art or ſcience, as yet unattained. Thus, it is a deſideratum with the blackſmith, to render iron fuſible, by gentle heat, and yet preſerve it hard enough for ordinary uſes; with the glaſs-man and looking-glaſs-maker, to render glaſs malleable; with the clock-maker, to bring pendulums to be uſeful where there are irregular motions; with the braſier and copperſmith, to make malleable ſolder; with the ſhipwright, to build veſſels that will ſail under water; with the diver, to procure manageable inſtruments for conveying freſh air to the bottom of the ſea ſufficient for reſpiration, and the burning of lights; with the aſſay-maſter, to melt or copel ores, or metals, immediately without the uſe of bellows or furnace; and with the carvers and joiners, to faſhion wood in moulds like plaſter of Paris, or burnt alabaſter, &c. And though, as Mr. Boyle obſerves, the obtaining of theſe deſiderata may be thought chimerical, yet it is proper they ſhould be propoſed; for although perfection may not be attainable, yet approaches to it may be made, and arts thereby improved. Vide Boyle's Works abr. vol. i. p. 129, 136. In ſhort, all arts and ſciences have their defects, and it is not at firſt to be gueſſed, for how many of theſe remedies may be found, by means of chemical and philoſophical reſearches, properly directed.

If a proper number of perſons duly qualified for making experiments, and improving from them, would ſet about each his particular ſhare of the neceſſary experiments, and communicate the reſult of all their proceſſes to one another, the buſineſs of chemical and philoſophical experiments would be much better directed in regard to future ſtudents, and many of the deſiderata in the art probably ſupplied.

DESIGN, from *deſigno, I mark out*, the plan, or repreſentation, of the order, general diſtribution, and conſtruction, of a painting, poem, book, building, or the like. The painter has ſhewn the firſt deſign of his piece, in which the figures are well diſpoſed. The deſign of that poem, or book, is artfully laid. Claudian never ſees his whole deſign together; when he compoſes a part he thinks of nothing elſe, and works up every member, as if it were ſeparate from all the reſt.

In building, we uſe the term ichnography, when by deſign is only meant the plan of a building, or a flat figure drawn on paper. Orthography, when ſome face or ſide of the building is raiſed from the ground. And ſcenography, when both front and ſides are ſeen in perſpective. See each article.

DESIGN, in *Muſic*, is the plan, ſubject, *prima intentione*, of a compoſition. It is not enough to produce good paſſages in the melody, and to accompany them with good harmony; the whole muſt ariſe out of, and have ſome connexion with, the ſubject. In all Haydn's beſt productions, where his invention ſeems inexhauſtible, the hearer is never allowed to forget the text; which, amidſt all the variety and contraſt of pathos, grace, ſpirit, and playfulneſs of the principal melody, is heard, by means of double counterpoint, in one part or other throughout the compoſition. Variety is perhaps more neceſſary in muſic than in poetry or painting; but that variety ſhould never amount to wildneſs, or incoherence, nor ſhould the regularity degenerate into monotony and dullneſs. To ſteer between theſe two extremes is the criterion by which we may eſtimate the judgment, genius, and experience of the maſter. The difficulty is to aſſociate with the melody, movement, character, harmony, modulation, and an elegant *variety;* without which, the whole becomes unintereſting and tireſome. The compoſer, as well as the poet and painter, may, doubtleſs, dare every thing in favour of this captivating variety; provided, under the pretence of contraſt, he gives us not for a well deſigned work, a *Cento* of unconnected paſſages of different character, which, as a whole, render the piece a monſter.

It is, therefore, in the intelligent diſtribution and arrangement of the ſeveral parts, that a perfect *deſign* conſiſts. In the latter productions of Mozart it is, that perfection of deſign appears. The early cultivation of his talents rendered him a profound critic, at an age when others are uſually beginning their ſtudies. In his firſt compoſition he was trying experiments, and vanquiſhing difficulties; but in his maturer years he gave way to his feeling, particularly in his vocal muſic, which was little known, except at Vienna, till after his death. But in his operas, both ſerious and comic, his deſigns are ſupported with ſo much ſimplicity, grace, and elegance, and fed with ſuch a conſtant flow of ideas, as if he had truſted to chance for arrangement.

DESIGN, in *Architecture, Engraving, Painting*, and *Sculpture*, is chiefly uſed for the general idea, or plan of a work, including the invention, compoſition, and arrangement of the whole; this being commonly ſketched out, or drawn. The terms deſign and drawing have become almoſt ſynonymous; and hence, perhaps, theſe arts have acquired the name of the arts of deſign: though it may be, becauſe they are all occupied in the expreſſion of forms; in the latter ſenſe, deſign conſtitutes one of the three elements of painting, chiaroſcuro and colouring being the others: this, however, is oftener called drawing, while deſign is applied to the invention and compoſition; ſo that, technically, a picture may be well drawn, though the deſign be bad, or *vice verſâ*. This diſtinction ſeems the better founded; the term deſign being uſed for a delineated invention (as the patterns in various ornamental manufactures, &c.), while

drawing oftener refers to the imitative, or executive part employed in repreſenting the appearances of objects. See INVENTION, COMPOSITION, PAINTING, and DRAWING.

DESIGN, in the *Weaving Manufactures*, ſignifies the pattern of any ornamented piece of cloth, when the ornaments are woven in the loom along with the fabric. A ſpecies of paper is uſed to lay down theſe ornaments to a ſcale, which is called deſign paper, and which ſerves to direct the weaver in his ſubſequent operations. In every ſpecies of ornamental weaving, the whole deſign is effected by the leaves of claſped twine, which move the various threads of that part of the yarn, which is ſtretched in the loom, and which is called the warp. Theſe leaves are called heddles in Scotland, healds in Lancaſhire, and may probably be known by other names in different parts of the country. The paper upon which the deſign is to be drawn, is ruled from top to bottom with a number of parallel lines, the intervals between which repreſent certain portions of warp. Theſe, being again croſſed by other parallel lines at right angles, the latter repreſent that part of the yarn which is inſerted by the ſhuttle, and which is called the woof or weft. The deſign-paper, when ruled, has the appearance of a number of ſmall ſquares, and in theſe the deſign is inſerted with a black lead pencil, or with any kind of water colour, very frequently with vermilion, or red lake. Every interval upon the paper may be ſuppoſed to repreſent either one or more threads. When it will not occupy too much ſpace, and when the deſign requires particular delicacy of ſhape, the moſt accurate way is to make every interval repreſent only one thread. At other times it frequently repreſents two, and ſometimes more.

The five figures in *Plate* IV., *Miſcellany*, repreſent the uſual modes of drawing deſigns for the ſpecies of ornamented cloth moſt commonly made in Great Britain. Different ways of effecting ornaments in the loom are practiſed, according to the fabric of the cloth, and the purpoſe to which it is to be applied. In the lighter manufactures of the ſilk, lawn, and muſlin trades, now chiefly uſed as ornamental parts of female dreſs, the fabric is generally ſo flimſy, that, when ornamented in the loom, the figures, in order to have any ſhow, muſt be compoſed of yarn, much coarſer than that which forms the ground or fabric of the cloth, and this yarn is ſometimes dyed of different colours. Being moſt convenient in general, and the patterns more eaſily changed, the weft, or woof, is moſt frequently uſed for this purpoſe. *Figures* 1 and 2, are repreſentations of this kind of work. In *fig.* 1, every ſquare of the deſign-paper is ſuppoſed to repreſent one thread both of warp and woof. In *fig.* 2, it is ſuppoſed to repreſent two. For the application of theſe deſigns to the purpoſes of mounting looms, ſee the article DRAUGHT and *Cording*.

In the heavier branches of the manufacture of cloth, ornaments are effected without any alteration in the fineneſs of either warp or woof, and moſt frequently without any change of colour. The *figs.* 3 and 5, refer to theſe kinds of work, and the ſquares in each of theſe may be ſuppoſed to repreſent any number of threads from three to eight, according to the fineneſs of the cloth, and labour beſtowed in ornamenting it. *Fig.* 4, is alſo a kind of ornamented cloth of the dimity kind of a ſtout fabric. Each ſquare upon the deſign repreſents one thread. For the application of theſe, ſee the reſpective articles DIAPER, DIMITY, DORNOCK, and DRAW-LOOM, eſpecially the laſt.

When deſigns are drawn upon paper, the diſtance of the lines is generally ſo much more than the diameters of the threads which they repreſent, that the figure upon the cloth will often be very different both in ſize and appearance from the deſign. To calculate this accurately is an important part of the buſineſs of a ſkilful manufacturer. The rules, therefore, for this, with references to the plate, will be found in the reſpective articles to which they refer.

Some general remarks upon the principle of deſigning ornaments upon cloth, and upon the analogy which ſubſiſts between the figure of any flower or pattern, when drawn upon plain paper, when reduced to the deſign-paper, and when woven into the cloth, may, however, be uſeful to thoſe who poſſeſs an adequate knowledge of the art of manufacturing plain cloth, but who are not equally converſant with the various branches of ornamental weaving.

When an oblique or curvilineal figure is drawn or painted, either upon canvas, paper, or any other ſubſtance, no impediment exiſts to prevent the artiſt from drawing every oblique ſtraight line at whatever angle of obliquity he chuſes, nor from forming whatever curves will add to the beauty of the picture. But, when an imitation of this is to be transferred to deſign-paper, and from thence to cloth, the ſame facilities do not exiſt, and the utmoſt which the moſt ſkilful weaver can effect is only the neareſt poſſible approximation to the original from which he copies. Every perſon at all acquainted with weaving knows, that the threads of warp are ſtretched in the loom, forming ſtraight lines parallel to each other, and that theſe threads are interſected by the woof at right angles. No oblique pattern can, therefore, be formed in the loom, except by varying the point in the warp, where the interſection ſhowing the pattern appears, and every change of this point muſt be at leaſt equal to the diameter of one thread. Now, if we ſuppoſe that there are equal quantities of warp and woof in a web, and that a ſhift of one thread of warp is made, to the right or left, every time that a thread of woof is paſſed acroſs, the diagonal line produced will form invariably an angle of 45° both with warp and woof. The diagonal here, then, is produced by the reſolution of two equal forces, acting at right angles to each other. But an obliquity, confined invariably to an angle of 45°, would produce a very limited range of patterns indeed. *Figs.* 1 and 2, are ſpecimens of ſuch as may be effected by it. It becomes, therefore, neceſſary, in more extenſive deſigns, to vary the obliquity of the angles frequently, and this can only be done in two ways.

1ſt. By ſhifting the point of interſection over more than one thread of warp, which will render the angle formed by the diagonal line and warp greater, and that by the diagonal and the woof leſs than 45°, or

2d. By inſerting more than one thread of woof without ſhifting the point of interſection, the effect of which will be exactly the converſe of the former.

It is to be obſerved, that by the diagonal line is only meant the apparent line which is preſented to the eye; for as the ſhifts are at right angles, each will form either a ſquare or parallelogram, the true diagonal of which is intended to be repreſented, and the means uſed are therefore only approximations to this.

When the deſign (*fig.* 5.) is examined, as all the ſquares forming the flower are black, whilſt thoſe which repreſent the ground are vacant, every ſhift, when minutely inſpected, is evidently at right angles, although the general effect, when viewed at ſome diſtance, has the appearance of diagonal or curved lines. But, were this pattern woven upon a fine cloth, the diameters of the threads would be ſo much leſs than the meaſures of the ſquares which repreſent them upon the paper, that the angular corners which give the edges of the flower the appearance of being dented, would totally

totally diſappear, unleſs very minutely inſpected, and the flower upon the cloth would be much ſmaller than that upon the paper.

The following table of the angles, formed between the diagonals of parallelograms, whoſe ſides are in the ſame ratio to each other as thoſe upon the deſign-paper, has been calculated to aſſiſt in reducing the drawing of deſigns, as nearly as poſſible, to correct imitations of the drawings or paintings from which they are taken.

TABLE ſhewing by inſpection the angles of obliquity formed by colouring the ſquares of deſign paper for weavers, both by the warp and woof, from 1 to 9 ſquares each way; the line of woof being taken as the baſe.

Squares of Warp.	Squares of Woof.								
	1	2	3	4	5	6	7	8	9
1	45°	27°	18°	14°	11°	9°	8°	7°	6°
2	63	45	34	27	22	18	16	14	13
3	72	56	45	37	31	27	23	21	18
4	76	63	53	45	39	34	30	27	24
5	79	68	59	51	45	40	36	32	29
6	81	72	63	56	50	45	41	37	34
7	82	74	67	60	54	49	45	41	38
8	83	76	69	63	58	53	49	45	42
9	84	77	72	66	61	56	52	48	45

The angles may be continued down to 1° and up to 89°, as follows: By the warp the number of ſquares to be coloured for one ſquare of woof will be for 85°, 11 ſquares; for 86°, 14 ſquares; for 87°, 19 ſquares; for 88°, 29 ſquares; and for 89°, 53 ſquares. And reverſing the operation for the ſame numbers the angles will reſpectively be the complements of thoſe quoted, *viz.* 11 ſquares 5°; 14 ſquares 4°; 19 ſquares 3°; 29 ſquares 2°; and 53 ſquares 1°.

To underſtand this table it is neceſſary to obſerve, that the left hand column from top to bottom contains the number of ſquares, coloured upon the deſign-paper, and forming the edge of the flower by the warp, or contained between one or more ſpaces from top to bottom of the paper. The croſs columns at the top contain the ſame by the woof, or acroſs the deſign, and the figures, where the one column croſſes the other, give the angle which the diagonal of a parallelogram, whoſe ſides are in the ratios of the two numbers to each other, would form with the baſe or croſs lines. When the number of coloured ſquares each way is equal, the angle is always 45°, and in all others the angle formed by the croſs ſquares is always the complement of the ſame number from top to bottom. The minutes have been thrown away, being unneceſſary in practice, and the neareſt degree, whether a little more or leſs, taken.

When a pattern is to be reduced from a common drawing to a deſign for weaving, this table may be of conſiderable uſe; for if a croſs line be drawn upon the original, the angles of obliquity may be taken with very conſiderable accuracy by a line of cords, or any of the uſual mathematical proceſſes, and a reference to the table will ſhew the number of ſquares which, when coloured, will produce the effect moſt nearly ſimilar. Curve lines are formed merely by changing the angles of obliquity, as frequently as neceſſary. When it is deſirable to make a ſmooth uniform line, it is always beſt to ſhift only one ſquare at a time, and make the ſhifts more frequent; for when many are ſhifted, the ſquare corners will be always too apparent; but where a rough edge is wanted, theſe may be reſorted to.

The calculation of the ſize of the flower upon the cloth, compared with that upon the paper, is merely a caſe of ſimple proportion. In order to calculate correctly, the greateſt number of ſquares coloured from right to left, and from top to bottom, muſt be counted, and the ſize of the flower each way meaſured; for deſign-paper is ruled to many different ſcales. The number of the reed, or, which is the ſame thing, the number of warp-threads in a given breadth, is then to be aſcertained, and alſo how many threads are repreſented by each ſquare. Theſe points being fixed, the ratio of the one to the other will be readily found. A ſingle example, taken from the damaſk flower, (*fig.* 5.) will illuſtrate this.

The ſquares coloured from right to left, counting from either extremity, are 107, and the meaſure is $5\frac{1}{8}$ inches.

From top to bottom the ſquares are 113, and the meaſure $5\frac{3}{8}$ nearly.

Let it be ſuppoſed that this pattern is to be wrought upon what is called a five leaf damaſk, containing 2400 threads in the compaſs of 37 inches. Every ſquare will then repreſent five threads either way; and the threads contained in the warp of one flower will be 535.

Then as 2400 : 37 :: 535 : 8.2479, or nearly $8\frac{1}{4}$ inches. The flower, therefore, upon this ſcale, will be $3\frac{1}{3}$ inches broader upon the cloth than upon the paper, and the exceſs of length will be found by a ſimilar proportion.

But were the ſame flower to be wrought as a ſpot, only two threads would be repreſented by each ſquare, and the number of warp-threads would be 214 in each flower. Suppoſe then the muſlin to be figured, to contain 3200 threads in 37 inches, the proportion would be

As 3200 : 37 :: 214 : 2.474, or nearly $2\frac{1}{2}$ inches. In this caſe the ſame flower, on the cloth, would be leſs than one-half of its breadth on the paper. The great diſproportion in the ſize of the two flowers depends partly upon the difference in the number of threads repreſented by one ſquare, and partly by the fineneſs or ſet of the webs. In the firſt, the ratio of decrement is *directly* as 2 to 5; in the ſecond, *inverſely* as 12 to 16.

When looms are mounted to work fanciful patterns, if the range is not too extenſive, heddles are uſed, which are moved by levers or heddles attached to them below by cords, and which are preſſed down by the weaver's feet. When the range of pattern becomes too extenſive to render this mounting convenient, another apparatus is adopted, which will be found in the articles DIAPER, MOUNTING, and the moſt extenſive in that of DRAW-LOOM. The more common mountings belong to the article DRAUGHT and *Cording*.

DESIGNATION, the act of marking or indicating, and making a thing known. The deſignation of ſuch an eſtate is made by the tenants, butments, and boundings. Among the Romans, there were deſignations of the conſuls and other magiſtrates, ſome time before their election.

DESIGNATOR, a Roman officer, who aſſigned and marked each perſon his place and rank in public ceremonies, ſhows, proceſſions, &c.

The word is formed from the verb *deſignare*, to deſign.

The deſignator was a kind of marſhal or maſter of the ceremonies, who regulated the ſeats, march, order, &c. There were deſignators at funeral ſolemnities, and at the games, theatres, and ſhows, who not only aſſigned every one his place,

place, but alſo led him to it; as appears from the prologue to the Pœnulus of Plautus.

Much of the ſame nature were the agonothetæ of the Greeks.

DESIGNING, the art of delineating, or drawing the appearance of natural objects, by lines on a plain.

To deſign, according to the rules of mathematics, makes the object of perſpective.

To deſign by the camera obſcura, ſee CAMERA *obſcura*, and DRAWING.

DESION, in *Chronology*, the Macedonian name of the Athenian month Antheſterion. See ANTHESTERION.

DE'SIRADE, LA, in Latin *Deſiderata*, in Spaniſh *Deſeada*, in *Geography*, one of the Caribbee iſles, or, according to the Engliſh denomination, one of the Leeward iſlands in the Weſt Indies belonging to the French, in the neighbourhood of Antigua, ſituated in N. lat. 16° 40′. W. long. 61° 20′; 18 miles N. E. of Guadaloupe, and 21 N. of Mariegalante. It is about 12 miles long and ſix broad.

At what time this ſmall iſland received its firſt inhabitants is not known, but although it was diſcovered by Columbus, it is yet a very modern colony.

In the year 1788, La Deſirade contained a population of 213 white, 33 mulattoes, or free negroes, and 619 negro ſlaves. There is no regular town. The ſoil is ſandy and not very fruitful; it yields ſome coffee and cotton. The iſland is however of ſome conſequence to the French in time of war, as it gives ſhelter to a number of privateers which annoy the Engliſh Weſt India trade.

DESIRE is defined by Mr. Locke to be the uneaſineſs a man finds in himſelf upon the abſence of any thing, whoſe preſent enjoyment carries with it the idea of delight; which is greater or leſs, as that uneaſineſs is more or leſs vehement. The uneaſineſs of deſire, fixed on ſome abſent good, is that, according to this writer, which determines the will, from time to time, to every voluntary action: nor does even the greater good, though apprehended and acknowledged to be ſuch, determine the will, until our deſire, proportionably excited, makes us uneaſy in the want of it. If it be enquired, what it is that moves deſire? He replies, happineſs, and that alone. This author has very properly diſtinguiſhed between will and deſire; though many later writers have overlooked this diſtinction, and have repreſented deſire as a modification of the will. Deſire and will agree in this, that both muſt have an object, of which we have ſome conception; and, therefore, both muſt be accompanied with ſome degree of underſtanding. Nevertheleſs they differ in ſeveral things. The object of deſire may be any thing, which appetite, paſſion, or affection leads us to purſue; it may be any event which we think good for us, or for thoſe to whom we are well affected. I may deſire meat, or drink, or eaſe from pain; but to ſay that I will meat, or will drink, or will eaſe from pain, is not Engliſh. There is, therefore, a diſtinction in common language between deſire and will. And the diſtinction is, that what we will muſt be an action, and our own action; what we deſire may not be our action; it may be no action at all. With regard to our own actions, we may deſire what we do not will, and will what we do not deſire; nay, what we have a ſtrong averſion to. Deſire, therefore, even when its object is ſome action of our own, is only an incitement to will, but it is not volition. The determination of the mind may be, not to do what we deſire to do. But as deſire is often unaccompanied by will, we are apt to overlook the diſtinction between them. Reid's Eſſays on the Active Powers of Man, p. 63.

DESIRE, *Port*, in *Geography*, a harbour on the coaſt of Patagonia, S. of cape Blanco, and about 3 leagues from Penguin iſland, having a remarkable rock, riſing from the water like a ſteeple, on the ſouth ſide of its entrance; and this rock ſerves as an excellent mark to know the harbour, which it would be otherwiſe difficult to find. The mouth of the harbour is very narrow, and has many rocks and ſhoals about it, and a very rapid tide running at the rate of eight miles an hour. The adjoining country for ſeveral miles is barren and deſolate, without a ſingle tree or ſhrub. It abounds with guanicoes, reſembling our deer, but much larger, ſome of them being 13 hands high, very ſhy and very ſwift, and an iſland within the harbour is covered with ſeals, many of which are larger than a bullock. Birds are alſo very plentiful.

DESISE, a town of France, in the department of the Saone and Loire, and diſtrict of Autun; 15 miles E. of Autun.

DESMAISEAUX, PETER, in *Biography*, was born at Auvergne in the year 1666. He came at an early age into this country, and acquired a very accurate knowledge of its language and literature. He was elected a fellow of the Royal Society, and is known chiefly by his editions of the works of Bayle and St. Evremond. To theſe he prefixed memoirs of the authors, in which are given many curious particulars of literary hiſtory and anecdote. He wrote the lives of Chillingworth and John Hales; and publiſhed a collection of pieces in philoſophy, hiſtory, mathematics, &c. from the works of Leibnitz, Newton, Clarke, Locke, and other diſtinguiſhed writers. He died in London in 1745. Moreri.

DESMARETS, HENRI, one of the moſt able French muſicians in the reign of Louis XIV., who having married a young lady with her own conſent, and that of her mother, was proſecuted by her father, and condemned to death by the chatlet, and had only time to ſave himſelf from an ignominious death by flight to Bruxelles, where he was appointed maeſtro di cappella to Philip V. king of Spain; and after remaining 14 years in Spain, quitting that country on account of the heat of the climate injuring his wife's health, he obtained the place of ſuperintendant of the muſic of the duke of Lorraine. He was obliged to remain a fugitive the chief part of his life, never having been able to obtain a pardon during the remainder of his inexorable father-in-law's days. However, in the year 1722, during the regency of the duke of Orleans, his ſentence was reverſed, and his marriage declared valid. He died in 1741, at the age of 80, having compoſed ſeven or eight operas, chiefly ſerious, which were much admired in their day.

DESMARS, NICHOLAS, phyſician to the town of Boulogne, was author of ſeveral uſeful publications on botany, mineralogy, and medicine, publiſhed about the middle of the laſt century. "Obſervations d'hiſtoire naturelle faites aux environs du Beauvais," 1749, treating of the air, water, plants and minerals found in the neighbourhood of the town, and of the diſeaſes peculiar to the place, and dependent, he thinks, on the water and ſoil. The work was reprinted, conſiderably enlarged, in 1759, and in 1762, 12mo. "Lettre concernant quelques plantes qui naiſſent en Picardie;" printed with the memoirs of the academy at Amiens, of which he was a member. He wrote alſo, in 1762, on a diſeaſe, then raging among the ſheep; and in the following year, on a ſimilar epidemic among dogs. In 1767, he publiſhed a tranſlation from the Greek, of the epidemics of Hippocrates, with notes and illuſtrations, 12mo., which is much commended, and has manifeſtly a reference to his firſt work. Haller Bib. Botan.

DESMOND, in *Geography*, the name of an ancient diſtrict of Ireland, which contained part of the preſent counties of Kerry

Kerry and Cork. The name implies South Munſter; and it was formerly ſubject to the M'Carthys, one of whom, as king of Deſmond, ſwore fealty to Henry II. After the Engliſh invaſion, the Fitzgeralds eſtabliſhed themſelves there by marriage, and became powerful ſupporters of the Engliſh intereſt in the ſouth. A branch of this family (from which are alſo deſcended the dukes of Leinſter, the earl of Kerry, and ſeveral reſpectable families of commoners,) was made earl of Deſmond in 1329. Far removed from the ſeat of government, theſe earls paid very little attention to its orders, and carried on frequent wars with the Ormond family, and other chieftains. The 16th earl was in open rebellion againſt queen Elizabeth, and being taken was beheaded on the ſpot, and his forfeited eſtates were divided amongſt Engliſh undertakers. His ſon died in priſon, in 1608, and the Deſmond branch of the Fitzgerald family ſoon after became extinct. The title was given to the family of Fielding. Smith's Cork, &c.

DESMOS, in *Botany*, (δεσμος, *a chain*, alluding to the chain-like, or rather beaded, form of the ſeed-veſſels,) a genus founded by Loureiro, Fl. Cochinch. 352. Claſs and order, *Polyandria Polygynia*. Nat. Ord. *Annonæ*, Juſſ.

Eſſ. Ch. Calyx of three leaves, flat. Petals ſix, lanceolate. Berries numerous, oblong, with numerous bead-like conſtrictions, each of which contains a ſingle ſeed.

Loureiro cites ſeveral plants as ſimilar to this genus, to which it has no affinity, nor ſcarcely any reſemblance; but he rightly indicates its relationſhip to *Uvaria*, *Annona*, &c. It is unqueſtionably of the ſame genus with *Uvaria zeylanica*, Aublet Guian. v. 1. 604. t. 243, (Funis muſæius, Rumph. Amboin. v. 5. 78. t. 42; Piper æthiopicum, Matth. Valgr. 526. Lob. Ic. v. 2. 205;) but ſcarcely with Narum Panel, Hort. Malab. v. 2. 11. t. 10, which laſt ſhould ſeem to be *Uvaria zeylanica* of Linnæus. It appears probable that the above plant of Aublet, which is a tree, and the two ſpecies in Loureiro, both ſmall ſhrubs and very nearly akin to each other, may properly belong to the genus *Unona*, Linn. Suppl. 44 & 270, the character of which would in that caſe require emendation; or rather perhaps the *Unona* itſelf, along with the plants in queſtion, ought altogether to be referred to *Uvaria*. S.

DESNY, in *Geography*. See Dezny.

DESOJA, a town of Spain, in Navarre; 10 miles S. W. of Eſtella.

DESOLATION, Cape, the S. E. point of the bay of St. Barbara, near the ſtraits of Magellan or Magelhaens, ſo called by captain Cook, becauſe near it commenced the moſt deſolate and barren country he ever ſaw. It is ſituated in S. lat. 54° 55′. W. long. 72° 12′. About four leagues to the eaſt of this cape, is a deep inlet, at the entrance of which lies a pretty large iſland, and ſome others of leſs note. Nearly in this ſituation ſome charts place a channel leading into the ſtraits of Magelhaens, under the name of ſtraits of Jelouzel. The coaſt is entirely compoſed of rocky mountains, without the leaſt appearance of vegetation. The mountains terminate in horrible precipices, whoſe craggy ſummits ſpire up to a vaſt height; ſo that hardly any thing in nature can appear with a more barren and ſavage aſpect, than the whole of this country. The inland mountains were covered with ſnow; (Dec. 19, 1774) but thoſe on the ſea-coaſt were not. The former were thought to belong to the main of Terra del Fuego, and the latter to be iſlands, ſo ranged, as apparently to form a coaſt.

Desolation *Iſland*, a name given by captain Cook in his third voyage to *Kerguelen's-land*, which ſee.

DE SON TORT Demesne, in our *Law*, words of form, uſed in an action of treſpaſs by way of reply to the defendant's plea. Thus, if A. ſues B. in ſuch an action, B. anſwers for himſelf, that he did that which it calls a treſpaſs by the command of C. his maſter. A. replies that B. did it "de ſon tort demeſne, ſans ce que C. luy commande modo et forma;" that is, B. did it of his own wrong, without C.'s commanding him in ſuch manner and form.

DESPAIR, is the thought of the unattainableneſs of any good, producing in ſome minds, and on ſome occaſions, uneaſineſs or pain; on others reſt and indolence.

Despair, in *Geography*, a bay on the ſouth-weſtern ſide of the iſland of Newfoundland, adjoining to Fortune bay on the north-eaſtward.

DESPARS, or De Partibus, James, in *Biography*, a native of Tournay, where he was born, towards the end of the fourteenth century, was in high reputation both as a divine, and as a phyſician. He was one of the canons, and treaſurer to the church at Tournay. In 1414, he was ſent by the univerſity at Paris, as one of the deputies to the council at Conſtance. He preſented to the univerſity a ſilver mace, in the year 1410, and in 1455, a ſecond, to be carried before the preſident; in conſideration of which the univerſity inſtituted a maſs, to be performed annually on the 4th of January, for the repoſe of his ſoul. Returning from his embaſſy to Conſtance, he retired to Tournay, where he died, in 1465. He left many works in manuſcript, ſeveral of which were thought ſufficiently important to be printed. The principal was a tranſlation and commentary on the canons of Avicenna. "Ego, Jacobus Deſpars," he ſays, in the preface, "de Tornaco, magiſter in medicina Pariſiis, expoſui ad longum totum primum librum canonis Avicennæ, incipiens anno Domini, 1432, et finiens anno 1453;" ſo that he employed twenty-one years on the work. The art of printing was divulged ſoon after the death of Deſpars, and this work was printed in four volumes folio, in 1498. In 1504, his "Gloſſa interlinearis in practicam Alexandri" was printed in 4to. at Lyons. Many other of his works were printed in ſucceſſion. They were of value in their time; but are now little noticed. For their titles, ſee Eloy. Dict. Hiſt.

DESPORTES, John Baptist, phyſician to the king of France, and correſpondent member of the Royal Academy of Sciences at Paris, was a native of Vitre, a town in Bretagne. After practiſing ſome years at Paris, he was appointed phyſician to the iſland of Domingo, where he died, after a reſidence of about ten years, in 1748. He left an intereſting and curious work, "Hiſtoire des Maladies de Saint Domingue," which was printed in the year 1770, in 3 vols. 12mo. Beſides an account of the diſeaſes common in Domingo, it contains deſcriptions of all the plants which the author found in the iſland. In this he has corrected ſeveral errors in the accounts left by Plumier, and Barrere, and has added, where he could obtain them, the names by which they were known by the native Caribbees; alſo a pharmacopœia, giving the qualities, or virtues, of the plants. Eloy. Dict. Hiſt.

Desportes, Francis, an eminent painter, was born at the village of Champigneul, in Champagne, in the year 1661; and being a diſciple of Nicaſius Bernard, imitated his manner of painting. The ſubjects which he ſelected were flowers, inſects, animals, and repreſentations of the chace, and theſe he deſigned and coloured with much truth; his local colours being very good, and the aerial perſpective well managed. He was chiefly employed in the ſervice of Lewis XIV.; and accompanied the French embaſſador, the duke d'Aumont, to London, where he was much encouraged. He died in 1743. Pilkington.

DESPOT, a title or quality given to the princes of Walachia,

Wallachia, Servia, and ſome of the neighbouring countries.

The word, in its firſt origin, ſignified the ſame with the Latin herus, and the Engliſh maſter: but, in time, it underwent the ſame fate on medals, as, among the Latins, Cæſar did with regard to Auguſtus; ΒΑCΙΛΕΥC anſwering to Auguſtus, and ΔΕCΠΟΤΗC, *deſpotes*, to Cæſar. See CÆSAR.

Thus, Nicephorus, having ordered his ſon Stauracius to be crowned, the ſon, out of reſpect, would only take the name ΔΕCΠΟΤΗC, leaving to his father that of ΒΑCΙΛΕΥC. For it is to be noted, that it was juſt about the time that the emperors began to ceaſe to uſe Latin inſcriptions.

This delicacy, however, did not laſt long; for the following emperors preferred the quality of ΔΕCΠΟΤΗC, to that of ΒΑCΙΛΕΥC, particularly Conſtantine, Michael Ducas, Nicephorus Botoniates, Romanus Diogenes, the Comneni, and ſome others.

In imitation of the princes, the princeſſes likewiſe aſſumed the title of ΔΕCΠΟΙΝΑ.

It was the emperor Alexius, ſurnamed the Angel, that created the dignity of deſpot, and made it the firſt after that of emperor, above that of Auguſtus, or Sebaſtocrator, and Cæſar. See AUGUST.

The deſpots were uſually the emperors' ſons, or ſons in-law, and their colleagues, or copartners in the empire, as well as their preſumptive heirs. The deſpots, that were ſons of the emperors, had more privileges and authority than thoſe that were only ſons in-law. Codin. p. 38. deſcribes the habit and ornaments of the deſpot. See the notes of father Goar on that author.

Under the ſucceſſors of Conſtantine the Great, the title deſpot of Sparta was given to the emperor's ſon, or brother, who had the city of Sparta, or Lacedæmon, by way of apannage.

DESPOTISM, or DESPOTIC *Government*, a form of government wherein the prince is abſolute and arbitrary, doing whatever he liſts, without being checked by any other power. Such are moſt of the eaſtern governments; as thoſe of the mogul, grand ſeignior, ſophi of Perſia, &c.

From the nature of a deſpotic power, it follows, that the ſingle perſon inveſted with this power, commits the execution of it alſo to a ſingle perſon. The creation of a vizir, ſays Monteſquieu, is a fundamental law of this government: and, accordingly, the Eaſtern kings are never without vizirs. As virtue is neceſſary in a republic, in a monarchy honour, ſo fear is neceſſary in a deſpotic government: as to virtue, there is no occaſion for it; and honour would be extremely dangerous. Perſons ſetting a value upon themſelves would be likely to create revolutions; and, therefore, fear muſt depreſs all their ſpirits, and extinguiſh every ſpark of ambition. As a deſpotic prince can have no notion of true glory, war is carried on under ſuch a government in its full natural fury, and a leſs extent is given to the law of nations, than in other ſtates. As fear is the principle of deſpotic government, its end, beſides the pleaſures of the prince, is tranquillity; a tranquillity, however, that cannot be called a peace; it is merely the ſilence of thoſe towns which the enemy is ready to invade. As the ſtrength does not lie in the ſtate, but in the army that founded it; in order to defend the ſtate, the army muſt be preſerved, how formidable ſoever to the prince. In deſpotic ſtates, religion, or rather ſuperſtition, has greater influence than any where elſe; it is a fear added to fear; and, therefore, it is not unaptly obſerved by Gibbon, that deſpotiſm originates in ſuperſtition; or it may be truly ſaid to derive its chief ſupport from it, in connection with the military power which it commands. In Mahometan countries, it is partly from their religion that the people derive the ſurpriſing veneration which they have for their prince. Of all deſpotic governments, there is none that labours more under its own weight than that wherein the prince declares himſelf the proprietor of all the lands and heir to all his ſubjects. Hence ariſes the neglect of agriculture; and if the prince intermeddles likewiſe in trade, all manner of induſtry is ruined. Under this ſort of government nothing is repaired or improved. In deſpotic governments, where the prince's brothers are equally his ſlaves and rivals, prudence requires that their perſons be ſecured; eſpecially in Mahometan countries, where religion conſiders victory or ſucceſs as a divine deciſion in their favour; ſo that they have no ſuch thing as a monarch *de jure*, but only *de facto*. The princes of deſpotic ſtates have always prevented the uſe of marriage. They generally take many wives, eſpecially in that part of the world where abſolute power is in ſome meaſure naturalized, *viz.* Aſia. Hence, they have ſuch a multitude of children, that they can hardly have any great affection for them, nor the children for one another. The reigning family reſembles the ſtate; it is too weak in itſelf, and its head too powerful; it ſeems very numerous and powerful, and yet is ſuddenly extinct. Poverty, and uncertainty of property, in a deſpotic ſtate, render uſury natural; each perſon raiſing the value of his money in proportion to the danger he ſees in lending it. Miſery, therefore, pours in from all parts into thoſe unhappy countries: they are bereft of every thing, even of the reſource of borrowing. Hence it is, that a merchant under this government is incapable of carrying on a great trade; for, if he were to encumber himſelf with a large quantity of merchandiſe, he would looſe more by the exorbitant intereſt he muſt give for money, than he could poſſibly get by his goods. A government cannot be unjuſt, without having hands to exerciſe its injuſtice. The embezzling of the public money is, therefore, natural in deſpotic ſtates. As this is a common crime under this government confiſcations are very uſeful. In this kind of government, authority muſt ever be wavering; nor is that of the loweſt magiſtrate leſs ſteady than that of the deſpotic prince. As the prince's will is the law, it is neceſſary that thoſe who will for him ſhould follow his ſubitaneous manner of willing. In deſpotic governments, of courſe, there are no laws; the judge is himſelf his own rule; and in theſe governments the prince himſelf may be judge. The principle of deſpotic government is ſubject to a continual corruption, becauſe it is in its very nature corrupt. Other governments are deſtroyed by particular accidents which do violence to the principles of each conſtitution: this is ruined by its own intrinſic imperfection, when no accidental cauſes impede or corrupt the principles on which it is founded. It maintains itſelf, therefore, only when circumſtances drawn from the climate, religion, ſituation, or genius of the people, oblige it to follow ſome order, and to admit of ſome rule. By theſe things its nature is forced without being changed: its ferocity remains; and it is made tame and tractable only for a time. From the nature, properties, and effects of a deſpotic government, one might imagine that it would meet with a general and perpetual oppoſition. But, notwithſtanding the love of liberty, ſo natural to mankind, notwithſtanding their innate deteſtation of force and violence, moſt nations, ſays Monteſquieu, are ſubject to this very government. This, he ſays, is eaſily accounted for. In order to form a moderate government, it is neceſſary to combine the ſeveral powers, to rule, temper, and ſet them in motion, to give, as it were, ballaſt to one, in order to enable it to reſiſt another.

This is a maſter-piece of legiſlation, rarely produced by hazard, and ſeldom attained by prudence. On the contrary, a deſpotic government offers itſelf, as it were, at firſt ſight; it is uniform throughout; and as paſſions only are requiſite to eſtabliſh it, this is what every capacity may reach.

As republics provide for their ſecurity by uniting, deſpotic governments do it by ſeparating, and by keeping themſelves, as it were, ſingle. They ſacrifice part of the country, ravage and deſolate the frontiers; and by theſe means render the heart of the empire inacceſſible. It preſerves itſelf, likewiſe, by another kind of ſeparation; which is, by putting the moſt diſtant provinces into the hands of a feudatory prince. The mogul, the king of Perſia, and the emperors of China, have their feudatories; and the Turks have found their account in putting the Tartars, the Moldavians, the Wallachians, and, formerly, the Tranſylvanians, between themſelves and their enemies.

DESPOUILLE, Fr. in *Heraldry*, is the whole caſe, ſkin, or ſlough, of a beaſt, with the head, feet, tail, and all appurtenances, ſo that, being filled, or ſtuffed, it looks like the entire creature.

DESPREAUX, in *Biography*. See Boileau.

DESPUMATION, of *de*, *priv.* and *ſpuma*, *froth*, the clarification of any liquor, by throwing up its foulneſs in a froth, and taking that off.

DESQUAMATION, from *de*, and *ſquamo*, *I ſcale*, expreſſes the flaking or ſcaling of carious bones. See Exfoliation.

DESS, in *Agriculture*, a term applied to any ſquare portion of cut fodder; thus, a deſs of hay ſignifies a cut of hay, &c.

Dess-*up*, ſignifies to pile up any ſort of cattle fodder, &c. in a neat manner.

DESSAU, in Latin *Deſſavia*, in *Geography*, a conſiderable town of Germany, in the principality of Anhalt Deſſau, in the circle of Upper Saxony, and reſidence of the prince of Anhalt Deſſau, whoſe dominions, ſince the peace of Tilſit, are in the conſcription of the new kingdom of Weſtphalia. Deſſau is ſituated in a delightful plain on the river Mulde, which, at a ſmall diſtance from the town, runs into the Elbe. The palace is a fine building; the ſtreets of the new part of the town are ſpacious and elegant. There are two Calviniſt churches and one Lutheran, a grammar-ſchool, ſeveral charitable foundations, and ſome manufactures of woollen cloth, ſtockings, and hats But Deſſau has more particularly acquired ſome celebrity within the laſt 30 years, from two inſtitutions eſtabliſhed here, one for the education of boys of good family, on principles nearly allied to thoſe ſuggeſted by J. J. Rouſſeau. This inſtitution, known by the name of *Philantropinum*, owed its origin to the celebrated Baſedow, (ſee Basedow,) who, for ſeveral years, conducted it with the greateſt ſucceſs, and whoſe elementary writings opened the career in which Campe, Villaume, Saltzmann, and other German literati, have ſo eminently diſtinguiſhed themſelves. The ſecond inſtitution, equally favourable to the diffuſion of knowledge, was a printing preſs and library, for the printing and publiſhing of works on account of their authors, without the interference of a bookſeller; the beneficial conſequence of which was, that the German publiſhers offered better prices for the manuſcript writings of men of known celebrity, and that young authors might feel the pulſe of the public taſte, by publiſhing their productions on their own account. Both theſe eſtabliſhments were warmly patronized by the prince, who is ſtill at the head of the principality of Anhalt Deſſau.

Near Deſſau are two ſummer palaces, Louiſium and Wörlitz, which ſee.

DESSENIUS, Bernard, in *Biography*, born at Amſterdam in 1510, was ſent firſt to Louvain, where he ſoon diſtinguiſhed himſelf by his acquirements in claſſical literature. Declaring at length for the practice of medicine, he went to Bologna, in Italy, and, in 1538, he took his degree of doctor in that faculty. A vacancy happening ſoon after at Groningen, he accepted the office of profeſſor, in the practice of medicine, which he taught with reputation for nine years. From thence, invited by Echtius, profeſſor in medicine there, he went to Cologne, where he approved himſelf ſo well, as to be admitted member of the college of phyſicians, and to receive a conſiderable penſion from the government. This he retained to the time of his death, which happened in 1574. He was author of ſeveral uſeful works. His "De Compoſitione Medicamentorum," fol. 1555, contains many valuable obſervations, and improvements on the formulæ, uſed in his time. "De peſte, Commentarius, preſervatio, et curatio," Col. 1564, 4to. He ſpeaks of a leathern jacket, which had paſſed into the hands of 25 perſons, who had received the infection from it, and been deſtroyed, before the cauſe was diſcovered. He wrote alſo in defence of the ancient medicine, and againſt the practice introduced by Paracelſus. Haller. Bib. Med. Pract.

DESSERT, or Desart, Fr. the laſt ſervice brought on the tables of people of quality, when the meats are all taken off. The deſſert conſiſts of fruits, paſtry-works, confections, &c.

DESSICATIVE, or Desiccative, from *deſicco*, *I dry up*, in *Medicine*, a remedy that has the virtue of drying up ſuperfluous moiſture; uſed to ſkin over old ſores, &c. We ſay, a deſiccative unguent, &c.

Pimpinella is held deterſive, deſiccative, and vulnerary. Lemery.

DESSOUBRE, in *Geography*, a river of France, which runs into the Doubs, at St. Hypolite.

DESTAKTUL, De, a Tartarian village of Siberia; 48 miles S.W. of Yakutſk.

DESTILLATION, or Distillation, in *Chemiſtry*. See Distillation.

DESTINIES, in *Mythology*. See Parcæ.

DESTINY, from *deſtino*, *I order*, the order, diſpoſition, or chain of ſecond cauſes appointed by Providence; and importing, or carrying with it, a neceſſity of event.

According to many of the heathen philoſophers, deſtiny was a ſecret and inviſible power, or virtue, which, with incomprehenſible wiſdom, conducted what to us appears irregular and fortuitous. This amounts to what we call God.

The Stoics, by deſtiny, underſtood a certain concatenation of things, which from all eternity follow each other of abſolute neceſſity, there being no power able to interrupt their connexion. This anſwers, in a great degree, to the ideas entertained by ſome of Providence.

But the Stoics made even the gods themſelves ſubject to the neceſſity of this deſtiny. The truth is, the Stoics rather define what the word deſtiny ſhould ſignify, than what it did ſignify in common language; for they had no diſtinct idea of this power, to which they attributed thoſe events. They had only a vague, confuſed idea of ſome kind of chimera, or unknown cauſe, to which they referred that invariable diſpoſition, and eternal concatenation of all things. There is no real being to which the ſame deſtiny can agree. The heathen philoſophers, who had framed a notion thereof, ſuppoſed it to exiſt, without knowing preciſely what they meant by it. But men, not daring on the one ſide to impute to Providence the evils and misfortunes that befel them, as they imagined, undeſervedly; and on the other ſide, not being

ing willing to allow that it was their own fault, formed this phantom of deſtiny, to bear the weight of all the evil.

DESTOUCHES, PHILIP NERICAULT, in *Biography*, was born at Tours in the year 1680. He was ſent early to Paris to ſtudy the law, but the conſequences of a love affair in which he engaged at ſixteen made it neceſſary for him to leave that ſituation; and having no reſources, he entered as a private ſoldier into a regiment then under orders for Spain. At the ſiege of Barcelona he narrowly eſcaped with his life. Shortly after this, he entered into a provincial company of players, with whom he viſited Switzerland, became the poet of the party, and compoſed a comedy which was acted with great applauſe in that country, and afterwards in France. While he was at Soleure, he attracted the attention of the marquis de Puyſieux, the French ambaſſador, who made him his private ſecretary, and obtained for him a reſpectable rank in life. On his return to Paris, he brought out with great ſucceſs ſeveral comedies: by theſe he was raiſed to a high rank among the writers of the time. He was afterwards ſent by the regent duke of Orleans to England as aſſiſtant to the abbé Dubois, in the negociations between the two courts. At the court of London he reſided 7 years as the ſole reſident: here he married, but circumſtances obliged him for ſome time to keep the matter a perfect ſecret. His conduct in England was highly approved, and duties of the ſame kind were afterwards offered him, which he declined, preferring a literary retreat to the buſineſs and buſtle of a diplomatic ſtation. At the age of ſixty, he devoted himſelf entirely, and employed his talents in the ſervice of religion. He died at the age of 74, and his works were collected and printed in four volumes quarto, which were afterwards publiſhed in 10 volumes 12mo. As a comic writer, he is inferior to Regnard in gaiety and humour, to Moliere, in truth and nature, and in unforced pleaſantry; but by many he is thought to deſerve the place next to theſe authors; he ſurpaſſes them in the morality and decorum of his pieces, and he had the art of attaining the pathetic without loſing the *vis comica*, which is the eſſential character of this ſpecies of compoſition. In the various connections of domeſtic life, he maintained a truly reſpectable character, and in early life, he gave evidence of his filial duty, by ſending 40,000 livres out of his ſavings to his father, who was burdened with a large family.

DESTOUCHES, ANDRE' CARDINAL, a voluminous compoſer of French operas on Lulli's plan, written chiefly by La Motte: theſe have been long forgotten; but his voyage to Siam with the abbé de Choiſis, is ſtill remembered. He died at Paris in 1749, aged 75.

DESTRUCTION, paſſively taken, is the corruption or annihilation of ſomething before exiſting. See CORRUPTION.

A thing paſſes from *eſſe* to *non eſſe*, either by corruption, when nothing of the ſubſtance is loſt, but only the accidents, *viz.* the diſpoſition of parts; or, by annihilation, when both ſubſtance and accidents are loſt.

DESTRUCTION *iſland*, in *Geography*, lies off the coaſt of New Albion, in N. lat. 47° 37'. W. long. 124° 11'. It is about a league in circumference, level, and almoſt entirely barrren, producing only a few dwarf trees; although the country to the ſouthward of it exhibits an appearance of the greateſt fertility.

DESUDABÆ, in *Ancient Geography*, a town of Thrace, in the country of the Mœdi, according to Livy.

DESUDATION, from *deſudo, I ſweat much*, expreſſes a profuſe and inordinate ſweating, followed by the irruption of ſudamina, or heat-pimples.

DESULTOR, from *deſilio, I vault*, in *Antiquity*, a vaulter, or leaper, who jumped off one horſe upon another.

Among the Scythians, Indians, and Numidians, the cavaliers, or horſemen, who ſerved in the wars, were very expert deſultores; that is, they always carried with them at leaſt two horſes, and when that they were mounted on grew weary, or wanted breath, they leaped with great agility and addreſs, upon the other which they led in their hand.

The Greeks and Romans borrowed the ſame practice from thoſe barbarous nations; but they only uſed it in their games, races, and funeral ſolemnities; and never, that we read of, in war. The deſultores, therefore, were, among the people of Aſia and Africa, ſoldiers; but, among the Romans, &c. they were no more than tumblers and poſture-maſters. Euſtathius, on Homer's Iliad, lib. iv. aſſures us, that inſtead of two, they had ſometimes four or ſix horſes all a-breaſt, and would jump from the firſt to the fourth or ſixth, which was the maſter-piece of their art.

DESUNNAY, in *Geography*, a river of Wales, in the county of Merioneth, which runs into the Iriſh ſea, five miles S.E. from Surnabugh point.

DESVRES, formerly called *Déſures*, and *Déſurennes* is a ſmall town of France, chief place of a canton, in the department of the Pas de Calais, diſtrict of Boulogne, 9 miles E. of that place. It has 2109 inhabitants. The canton reckons a population of 9443 individuals, diſtributed in 23 communes, on a territorial extent of 195 kiliometres.

DESUVIATII, in *Ancient Geography*, a people of Gallia Narbonnenſis, who occupied, according to Pliny, the vicinity of the Anatilians and Cavarians, on the banks of the Rhone. D'Anville places them N. of Arelate.

DESWARTE, in *Geography*, a river of Brabant, which runs into the Demer, near Dieſt.

DETACHE', *Fr.* A term in *Muſic* equal to *ſciolto* or *ſtaccato*, Ital. and detached, ſeparated, accented, and cut, in Engliſh: when, inſtead of ſuſtaining the notes during their whole value, they are performed as if there was a reſt after each, equal to half the length of the note it follows. This ſhort and dry manner of executing the notes is uſually expreſſed by lengthened points, or accents, thus ‴

DETACHED PIECES, in *Fortification*, are demi-lunes, ravelins, horn and crown-works, and even baſtions, when ſeparated, or at a diſtance from the body of the place.

In painting, the figures are ſaid to be well detached, or looſened, when they ſtand free and diſengaged from each other, are no where confounded together, but ſtand out with a ſtrong relievo from the ground, and from each other.

DETACHMENT, as a military term, refers to the ſending away a portion of any force upon any particular ſervice. We generally conſider a detachment to be rather a ſmall portion of the whole body; viewing it as ſtill appertaining thereto, and acting under the authority by which it was detached. Thus eſcorts, foraging-parties, &c. whether from one corps, or compoſed of drafts from ſeveral, though all of different claſſes, ſuch as horſe, infantry, artillery, engineers, pioneers, &c. all come under this denomination.

It is perhaps difficult to adduce any part of the military ſcience that requires more judgment than the detachment of various parties for the neceſſary purpoſes of ſupply, communication, ſurprize, or reinforcement. When we look back into the annals of military events, there appear numberleſs inſtances of ruin occaſioned by the injudicious and incautious manner of detaching ſmall parties from the main body. Hence we cannot but coincide with the practice of the greateſt generals, ſuch as the duke of Marlborough, marſhall Turenne, prince Eugene, the great Frederick, the no leſs

admirable Washington, and many others, who seemed to avoid detachments, at least small ones; considering them, no doubt, as being easily cut off. Those generals usually kept their forces as much concentrated as the means of subsistence, lodging, &c permitted.

The general who sends out numerous small detachments in various directions, while in the vicinity of an enemy, subjects them to be cut off in detail, and to have his head-quarters attacked by any enterprizing partizan. It should ever be recollected, that detachments generally are forced to self-preservation, and leave to the care of the main body such others as may not be within sight: hence, when attacked in their rear, these small parties are ordinarily obliged to surrender. Nor is it advisable, even in a friendly country, to allow too much dispersion of a force; for when riots happen, or that orders are suddenly received for a new destination, it will be found more difficult, than common observers may suppose, to rescue from danger in the former case, or to concentrate the whole in the latter instance, so as to move off in full force, with alacrity and due order.

In short, small detachments, like centinels too far removed from their posts of relief, are open to every danger, and in the end perform very insignificant services. In many instances it is better to move a large army, to effect what may be considered comparatively trifling, rather than to subject a small portion to the danger of being cut off.

Detachment *of a fleet or squadron*, a certain number of ships chosen by an admiral or commodore from the rest of the fleet, and charged to execute some particular service.

DETAINER, in *Law*. See Forcible *entry*.

DETENT, in *Horology*, is a piece of steel that detains or arrests the motion of one wheel that would otherwise continue its motion as actuated by the maintaining power. In the striking part of a clock, where a count-wheel is used, that bar which falls in the way of the notches in the count-wheel, and stops the motion of the striking train when the last blow is made, is called the detent: but in a chronometer, that piece of metal which catches a tooth of the escapement-wheel, and holds it while the balance performs its oscillation, is the detent; and may, according to the French constructions, turn on pivots, or otherwise be made elastic without pivots, agreeably to the English practice. Many of the clock-escapements also have detents, as may be seen more particularly under our article Escapement.

DETENTION, from *detineo, I detain*, in *Law*, the possession or holding of lands, or the like, for some other claimant.

The word is chiefly used in an ill sense, for an unjust withholding, &c.

The canons condemn a person who has intruded into a benefice, to make restitution of all the fruits thereof, during the time of his unjust detention.

DETERGENTS, in *Medicine* and *Surgery*, constitute a class of remedies which have been supposed to cleanse or deterge unhealthy humours. The old theories on this subject are now wholly exploded; but the fact remains, that certain substances applied to morbid parts, and especially to sores, will render the surface more clean and healthy.

Detergents are either mechanical or chemical. Pure water is one of the best detergents for common wounds: but where an ulcer remains sordid and ill-conditioned, it is often useful to apply a solution of some irritating substance, which produces an healthy discharge of pus. See the articles Abstergent and Cicatrix.

The detergents in general use for local applications, are turpentine, nitre, verdigris, alum, vitriolated zinc and copper, red nitrated mercury, or red precipitate, lunar caustic, or nitrated silver, &c. But, for internal use, physicians prescribe what are called balsamic medicines, absorbents, and vulneraries, which have been erroneously imagined to act as healing, suppurating, and cleansing remedies, to the internal parts of the body.

DETERIORATION, an act whereby a thing is impaired or rendered worse.

When the deterioration of a commodity, seized by an officer, arises from the fault of the keeper, he is answerable for the same.

J. Frederic Mayer, professor at Leipsic, printed a treatise of deterioration, in the year 1695, under the title of "Tractatus de Deterioratione."

DETERMINATE Number. See Number.

Determinate *Problem*, is that which has but one, or at least but a certain number of solutions; in contradistinction to an indeterminate problem, which admits of infinite solutions.

Such, *e. gr.* is the problem: To describe an isosceles triangle on a given line, whose angles at the base shall be double that at the vertex: which has only one solution; as that which follows has two, *viz.* To find an isosceles triangle, whose area and perimeter are given.

A determinate problem may either be simple or linear, plane, solid, or surfolid.

Determinate *Ramosus*, *Caulis*, in *Botany*, is often applied by Linnæus, in his later works, to that kind of stem which may be called abruptly branched, each branch, after terminating in flowers throwing out a number of fresh shoots, in a circular order, just below the origin of those flowers. This term does not occur in the Philosophia Botanica, nor any other elementary work of the learned Swede. It is exemplified in many species of Heath, as well as in the genus *Azalea*. See Caulis.

DETERMINATION, in *Physics*, the disposition or tendency of a body towards one way, rather than another. Heavy bodies have a determination towards the centre of the earth.

Determination is also used for the action whereby a cause or agent is limited, or restrained, to act, or not act, in this or in that manner.

Determinations, say the schoolmen, proceed either from an efficient cause, in which case the determination is called effective; as, when an artist determines an instrument to a certain action; or from the form, as that determines the indifferency of the matter: and thus our senses are said to be determinations to have ideas upon the presence of external objects.

Or the determination is from the matter or subject that receives the action; and thus the heating of fire upon clay determines it to harden, upon wax to soften, &c.

Or it is from the object; as when we say, colour determines the visual power: or, lastly, it is from the end, as the end determines the desire.

Determinations, again, are either moral or physical. A moral determination is that proceeding from a cause which operates morally, *i. e.* by commanding, persuading, or advising, some effect. This is the only kind of influence or determination which is consistent with man's free moral agency; or indeed with any agency at all.

Physical determination is an act whereby God excites and applies a second cause to act, antecedently to all operation of the creature. Such a determination the Thomists and Dominicans maintain necessary to all the actions of every creature. The Jesuits, on the contrary, deny that God thus determines even second causes; and hold, that God exerts no influence on second causes, but only with the second cause on the action. And thus they exclude a physical determination,

termination, both from natural cauſes, as ſuppoſing them already determined by nature to act; ſo that there needs no other external determination from God to the ſeveral actions; and from free cauſes, as ſuppoſing ſuch a predetermination contrary to our natural liberty. See DESIRE, MOTIVE, VOLITION, and WILL.

A determination to be pleaſed with certain forms, or ideas, an ingenious author calls an internal ſenſe; and a determination to be pleaſed with virtuous actions, characters, manners, &c. a moral ſenſe. See SENSE.

DETERMINATION *of Will*, in *Law*. See ESTATE *at Will*.

DETERMINATIVE PROPOSITION, in *Logic*. See COMPLEX *Propoſition*.

DETERN, in *Geography*, a ſmall town of Holland, in the principality of Eaſt Frieſland, which, till the peace of Tilſit in July 1807, belonged to the king of Pruſſia. This place has lately become faſhionable on account of its mineral waters.

DETERRATION, from *de* and *terra*, is uſed to ſignify a removal of the earth, ſands, &c. from the mountains and higher grounds, down into the valleys and lower parts. This is occaſioned by rains, which waſh the earthy matter down by degrees; but this cannot be very conſiderable, or much raiſe the ſurface of the earth, as ſome have imagined, becauſe a good part of it is ſunk into the clefts and caverns of the rocks and mountains, a great quantity is borne down into rivers, and thence into the ſea, and the richer and finer parts help to compoſe the bodies of plants and vegetables. From this deterration or devolution, as the diſintegration of mountains is called by Woodward and others, the ſecondary ſtrata of the earth, according to ſome theories of geology, had their origin.

DETERSIVE, in *Surgery*, the ſame with *Detergent*, which ſee.

DETERSOR, from *detergo*, *I clear away*, in *Antiquity*, a ſervant whoſe buſineſs it was to attend at dinner, and wipe the table. Pitiſc.

DETERSORIUM, in *Antiquity*, a name given to the common waſh, which was bean-meal, called *lomentum*, or the meal of a ſort of pulſe called *lupines*: this laſt they called *ſmegma*.

The ancients, when they bathed, uſed various waſhes for cleanſing the ſkin; but *natrum*, and this thin froth, called in Greek *aphronitron*, were moſt common.

DETHARDING, GEORGE, in *Biography*, was born at Stetin, about the middle of the 17th century. His father was an apothecary, and well verſed in chemiſtry, to the knowledge of which, having initiated his ſon, he ſent him to Louvain, where he took his degree of doctor in medicine; he was thence invited to Stralſund, and having practiſed medicine there ten years, he was in the year 1680 appointed firſt phyſician to the duke of Mecklenburg. This obliged him once more to change his habitation, and to go and reſide at Guſtrow. He appears to have been living at Guſtrow as late as the year 1696, when he publiſhed his "Nomenclator Chirurgicus." Several of his communications were publiſhed in the Memoirs Academ. Nat. Cur. A ſtill greater number of his eſſays, or diſſertations, were publiſhed by his ſon after his death. The titles of a few of theſe follow; the remainder will be found in Haller's Bib. Med. and in Eloy's Dict. Hiſtor.; *viz.* "De modo ſubveniendi ſubmerſis in Aqua, per Laryngotomiam," Roſtoch, 1714, 4to. The practice has not been much followed, but in extreme caſes ſhould not be omitted; the operation neither requiring much ſkill in the performance, nor being attended with danger. "De Variolarum Inoculatione," 1723, 4to. He was one of the few writers on the continent, who at that early period recommended the practice. "De neceſſitate inſpectionis vulnerum in crimine homicidii," 1726, 4to. Eloy gives the titles of twenty different eſſays.

DETINET, in *Law*. See *Debet* and *Detinet*.

DETINUE, a writ which lies againſt a man who, having goods, or chattels, delivered to keep, refuſes to re-deliver them.

Detinue anſwers, in great meaſure, to the *actio depoſiti* of the civilians.

In this action of detinue it is neceſſary to aſcertain the thing detained, in ſuch manner as that it may be ſpecifically known and recovered. Therefore, it cannot be brought for money, corn, or the like; for that cannot be known from other money or corn; unleſs it be in a bag or ſack, for then it may be diſtinguiſhably marked. In order, therefore, to ground an action of detinue, which is only for the detaining, theſe points are neceſſary (Co. Litt. 286.); 1. That the defendant came lawfully into poſſeſſion of the goods, as either by delivery to him, or finding them; 2. That the plaintiff have a property; 3. That the goods themſelves be of ſome value; and, 4. That they be aſcertained in point of identity. Upon this the jury, if they find for the plaintiff, aſſeſs the reſpective values of the ſeveral parcels detained, and alſo damages for the detention. And the judgment is conditional, that the plaintiff recover the ſaid goods, or (if they cannot be had) their reſpective values, and alſo the damages for detaining them (Co. Entr. 170. Cro. Jac. 681.) But there is one diſadvantage which attends this action; *viz.* that the defendant is herein permitted to wage his law, that is, to exculpate himſelf by oath (Co. Litt. 295.), and thereby defeat the plaintiff of his remedy; which privilege is grounded on the confidence originally repoſed in the bailee by the bailer, in the borrower by the lender, and the like; from whence aroſe a ſtrong preſumptive evidence, that in the plaintiff's own opinion the defendant was worthy of credit. For this reaſon, the action itſelf is of late much diſuſed, and has given place to the action of *Trover*; which ſee.

DETINUE *of Charters*. A man may have detinue for deeds and charters concerning land: but if they concern the freehold, it muſt be in C. B. and no other court. Action of detinue lies for charters which make the title of lands: and the heir may have a detinue of charters, although he hath not the land. If my father be diſſeiſed, and dieth, I ſhall have detinue for the charters, notwithſtanding I have not the land: but the executors ſhall not have the action for them. New Nat. Br. 308.

DETINUE *of goods in frank marriage*, is on a divorce betwixt a man and his wife; after which the wife ſhall have this writ of detinue for the goods given with her in marriage. Mich. 35 Eliz. 1. New Nat. Br. 308.

DETMOLD, or DETHMOLD, anciently *Thietmal*, in *Geography*, an inconſiderable but very old town of Germany, in the county of Lippe, in the circle of Weſtphalia, which is now in the conſcription of the new kingdom of Weſtphalia. It is ſituated on the river Werre, three miles S. of Lemgow, 18 N. of Paderborn, and has a caſtle, which is the uſual reſidence of the counts of Lippe. The town is divided into the old and new town. It has a very excellent grammar ſchool. Cluverius and others ſuppoſe that Detmold is actually the ancient Teutenburg, in the vicinity of which the Roman general Quintilius Varus met with a ſevere defeat.

DETONATION, in *Chemiſtry*, is ſudden combuſtion, attended with a loud and inſtantaneous noiſe. It is ſynonymous with fulmination.

DETONNER, *Fr.* in *Muſic*, to ſing or play out of time, or in falſe intervals, that are equally offenſive in a ſingle part, as in harmony.

DETOUR,

DETOUR, in *Geography*, in Upper Canada, the entrance into lake Huron from Muddy lake to the S. and W. of St. Joſeph's iſland.

DETOUR alſo lies on the N. ſhore of lake Huron, a little to the E. of the iſles au Serpent.

DETOUR *Point* lies on the W. main, in the ſtrait made by St. Joſeph's iſland.

DETOUR *des Anglois*, or *Engliſh Turn*, is a circular direction of the river Miſſiſſippi, ſo conſiderable that veſſels cannot paſs it with the ſame wind that conducted them to it. The two forts and batteries at this place on both ſides of the river are more than ſufficient to ſtop the progreſs of any veſſel. Dr. Cox, of New Jerſey, aſcended the Miſſiſſippi to this place, A. D. 1698, took poſſeſſion, and called the country Carolina. It lies 18 miles below New Orleans, and 87 above the Balize. The banks of the river are ſettled and well cultivated from hence to New Orleans, and there is a good road for carriages all the way.

DETOUR, in the *Military Art*, ſignifies that circuitous route taken by a body of troops, for the purpoſe of evading obſervation, or of paſſing round the flank of an enemy, ſo as to come by ſurpriſe againſt ſome weak part: or to force a paſſage at a point on which the general ſucceſs of the day might depend.

Detours are uſually made in the night time, and require the utmoſt caution. Silence ſhould, as much as poſſible, be obſerved, and the whole equipment ought to be made in a manner ſuitable to the main intention. The men ſhould be ſelected; the ordnance, (if any be uſed,) ſhould be light and well ſupplied with horſes, &c.; and nothing ſhould be allowed to accompany, which could, in the ſmalleſt degree, retard the movement, or require time for arrangement when arrived at the place of attack.

Unhappily our allies have, in almoſt every inſtance, allowed themſelves to be taken in flank, or even to be aſſaulted in their rear, by neglecting to take poſitions which rendered the acceſs by detour difficult: hence we have commonly witneſſed, with pain, that many advantageous movements have been rendered nugatory, indeed fatal, by the neglect of guarding againſt this device: a device which we muſt ever expect an enterpriſing enemy will perpetually reſort to, when his main body may be ſtrongly poſted (if inferior,) or be capable of ſhewing a ſufficient front.

When two different columns, or diviſions, intend to attack by detour, at any given point of the enemy's flank or rear, the utmoſt precaution ought to be uſed to arrive preciſely at the appointed hour, and to diſtract the attention of the troops to be ſurpriſed. Sometimes an attack is made openly by one column, while another makes a ſecret detour with the view to cut off the retreat of the enemy, if he be overpowered; or to create a diverſion in caſe the conteſt ſhould be ſevere, and doubtful. In ſuch caſes much hazard is incurred by both columns; therefore the manœuvre muſt be very cautiouſly managed, and ought to be confided to the ſuperintendance of officers diſtinguiſhed for their courage, diſcretion, and preſence of mind.

DETRAHENS QUADRATUS, in *Anatomy*, a name given by ſome authors, particularly Spigelius, to a muſcle, called by the generality of anatomiſts the platyſma myodes; and, by Albinus, latiſſimus colli. Douglas calls it alſo quadratus genæ. See DEGLUTITION.

DETRANCHE', among the *French Heralds*, ſignifies a line bendwiſe, which does not come from the very dexter angle, but either from ſome part of the upper edge, and thence falling athwart, or diagonally; or form part of the dexter ſide. They ſay, *tranché*, *detranché*, and *retranché*; to denote that there are two diagonal lines, making two partitions in the eſcutcheon, and coming from the angles, and a third from ſome of the other parts above mentioned. See TRANCHE'.

DETRITUS, in *Geology*, is a term uſed for the ſmall fragments and matters formed by the ſuppoſed diſintegration of the primeval mountains of the globe, by the Moſaic and other deluges, which, according to the theories of ſome, have contributed to the formation of the *ſtrata*, which ſee.

DETROIT, in *Geography*, a port town, the principal and the beſt fortified in the country N. W. of the Ohio river. It is the chief town of the county or territory of Wayne, and is ſituated on the weſtern bank of the ſtrait St. Clair, or Detroit river, between lake Erie and lake St. Clair; 18 miles N. of the W. end of the former, and 9 miles below the latter. Detroit contains about 300 houſes, and 1200 inhabitants: it ſtands contiguous to the river, on the top of the banks, which are here about 20 feet high. At the bottom of them there are very extenſive wharfs for the accommodation of the ſhipping, built of wood, ſimilar to thoſe in the Atlantic ſea-ports. The town conſiſts of ſeveral ſtreets that run parallel to the river, which are interſected by others at right angles. They are all very narrow, and not being paved, extremely dirty in wet weather; but for the accommodation of paſſengers there are foot-ways in moſt of them, formed of ſquare logs, laid tranſverſely cloſe to each other. The town is ſurrounded by a ſtrong ſtockade, through which there are four gates; two of them open to the wharfs, and the two others to the N. and S. ſides of the town reſpectively. The gates are defended by ſtrong block-houſes, and on the W. ſide of the town is a ſmall fort in the form of a ſquare, with baſtions at the angles, and having one ſide which commands the river. At each of the corners of this fort is planted a ſmall field-piece: and theſe conſtitute the whole of the ordnance at preſent in the place. The Britiſh kept a conſiderable train of artillery here, but the place was never capable of holding out for any length of time againſt a regular force: the fortifications, indeed, were conſtructed chiefly as a defence againſt the Engliſh. Detroit is at preſent the head-quarters of the weſtern army of the ſtates: the garriſon conſiſts of 300 men, who are quartered in barracks. About two-thirds of the inhabitants of Detroit are of French extraction; and the greater part of the inhabitants of the ſettlements on the river, both above and below the town, are of the ſame deſcription. The former are moſtly engaged in trade, and they all appear to be much on an equality. This is a place of very conſiderable trade; there are no leſs than twelve trading veſſels belonging to it, brigs, ſloops, and ſchooners, of from 50 to 100 tons burthen each. The inland navigation in this quarter is indeed very extenſive; lake Erie, 300 miles in length, being open to veſſels belonging to the port, on the one ſide, and lakes Michigan and Huron, the firſt upwards of 200 miles in length, and 60 in breadth, and the ſecond no leſs than 1000 miles in circumference, on the oppoſite ſide; beſides lake St. Clair and Detroit river, which connect theſe former lakes together, and many large rivers which fall into them. The ſtores and ſhops in the town are well furniſhed with fine cloth, linen, &c.; and its chief trade conſiſts in a barter of coarſe European goods with the natives for furs, deer-ſkins, tallow, &c. The inhabitants are well ſupplied with proviſions of every deſcription, and particularly fiſh, of which the moſt eſteemed is a ſort of large trout, called the "Michillimakin," or white fiſh, from its being caught moſtly in the ſtraits of that name. The want of ſalt was, till of late, attended with great inconvenience: but ſalt ſprings have been diſcovered in various parts of the country, and they are now beginning to manufacture this article for

for themſelves. Some of the ſprings in the weſtern country throw up water ſufficient to yield ſeveral hundred buſhels in the courſe of one week.

There is a large Roman Catholic church in the town of Detroit, and another on the oppoſite ſide, called the Huron church, from its having been devoted to the uſe of the Huron Indians. The ſtreets of Detroit are generally crowded with Indians of one tribe or the other; and amongſt them you ſee numberleſs old ſquaws leading about their daughters, ever ready to diſpoſe of them, *pro tempore*, to the higheſt bidder. At night all the Indians, except ſuch as get admittance into private houſes, and remain there quietly, are turned out of the town, and the gates ſhut upon them. The country round Detroit is very much cleared, and ſo is that on the Britiſh ſide of the river for a conſiderable diſtance above the town. The ſettlements extend nearly as far as lake Huron; but beyond the river La Trenche, which falls into lake St. Clair, they are ſcattered very thinly along the ſhores. The banks of the river La Trenche, or Thames, as it is now called, are increaſing rapidly in population, on account of the great emigration thither of the people from the neighbourhood of Niagara, and alſo of Detroit, ſince it has been evacuated by the Britiſh. The country round Detroit is uncommonly flat, and none of the rivers have a fall ſufficient for turning even a griſt-mill: their corn therefore is ground by wind-mills. The ſoil of the country bordering upon Detroit river is rich though light, and it produces good crops both of Indian corn and wheat. For eight miles below, and about the ſame diſtance above fort Detroit, on both ſides of the river, the country is divided into regular and well cultivated plantations; and from the contiguity of the farmers' houſes to each other, they appear like two long extended villages. The climate is much more healthy than that of the country in the neighbourhood of Niagara river; although intermittent fevers are not uncommon diſorders. The ſummers are intenſely hot, Fahrenheit's thermometer often riſing above 100; and yet a winter ſeldom paſſes over without ſnow remaining on the ground for two or three months.

By the treaty of Grenville, Aug. 1795, the Indians have ceded to the United States the port of Detroit, and all the land to the N., W., and S. of it, of which the Indian title has been extinguiſhed by gifts or grants to the French or Engliſh governments; and ſo much more land is to be annexed to Detroit as ſhall be comprehended between Roſine river on the S.; lake St. Clair on the N.; and a line, the general courſe of which ſhall be ſix miles from the W. end of lake Erie and Detroit river. The fort was delivered up by the Britiſh in July, 1796, according to treaty. It lies 18 miles N. of lake Erie, 724 N.W. by W. from Philadelphia, N. lat. 42° 40'. W. long. 82° 56'. Weld's Travels through North America, vol. ii. Morſe. See MALDEN.

DETROIT *river*, or *Strait of St. Clair*, iſſues from lake St. Clair, and enters the weſt end of lake Erie forming part of the boundary between the United States and Upper Canada. In aſcending it, its entrance is more than three miles wide, but it is perceptibly diminiſhed: ſo that oppoſite to the fort, 18 miles from lake Erie, it does not exceed half a mile in width; from thence to lake St. Clair it widens to more than a mile. The channel of the ſtrait is gentle, and wide and deep enough for ſhipping of great burthen, although it is incommoded by ſeveral iſlands, one of which is more than ſeven miles in length. The ſoil of theſe iſlands is fertile, and by their ſituation preſent an agreeable appearance. The length of the river is 28 miles, and ſeveral ſtreams fall into it, chiefly from the N.W.; *viz.* Bareche, Clora, Gueriere, Detroit, and Huron rivers. On the Detroit are ſeveral windmills, and an orchard adjoins to almoſt every houſe. The ſettlers are numerous, and the improvements extenſive. When the fruit-trees are in bloſſom, the proſpect as you paſs through the ſtrait is as delightful, perhaps, as any in the world.

DETROIT, *le Petit*, lies on the Ottawa river, in Upper Canada, below the upper main forks of the Ottawa river.

DETROIT, in a *Military Acceptation*, relates to thoſe ſituations which appear to be the natural embouchures, or entrances, of areas encloſed among mountains, wilderneſſes, &c. beyond which an army cannot penetrate; ſuch areas being acceſſible from no other quarter. Many large tracts are ſo happily ſituated as to be invulnerable on every ſide, except at a detroit, or ſtraight, where a very ſhort line of defence ſuffices to keep the encloſure perfectly ſecure.

When an army retires to a *Cul-de-ſac* (*i.e.* literally the bottom of the bag,) it may be eaſily excluded from further operations in the field, by a comparatively ſmall force; provided the very entrance is occupied by the detaining power. But if the detroit expands gradually towards the open country, and that there be heights which command the funnel, or entrance, it will demand a ſuperior number to prevent thoſe who have retreated thereto, from iſſuing forth at pleaſure; becauſe the batteries (or flankings) alone, would prevent the occupancy of thoſe poſts that might keep the embouchure cloſely guarded, and prevent the ſaliant column from deploying into line as the ground might admit of enlarging the front.

Nothing can be more favourable than taking poſt in a cul-de-ſac, whoſe entrance is a detroit. When the poſition can be maintained by means of abundant ſtores, both of proviſion and of ammunition; and when the ſituation is airy and healthy; but, on the other hand, nothing can be more hazardous, indeed, more entirely fatal, than the retreat to ſuch, when either proviſion, or ammunition, is likely to fall ſhort. In ſuch caſes a ſurrender muſt take place; as, on two or three occaſions happened to the Romans, who were compelled to lay down their arms, and to paſs under the yoke. A good general, who has confidence in his troops, will, however, do his utmoſt to force the paſſage of the detroit, if it be in the hands of the enemy; if it be in his own poſſeſſion, he will ſally forth, in ſo determined and pointed a manner, as may awe his oppoſers, and, in all probability, obtain either a complete releaſe, or honourable terms, for the gallant troops under his command. The fortifications thrown up at the place where the river St. Lawrence becomes extremely narrow at its fall into lake Erie, in Canada, were deſignated Detroit, on account of the manner in which the adjacent country, as well as the river contracts, and forms a very limited debouchure from the upper country.

DETRUSOR URINÆ, in *Anatomy*, the muſcular covering of the bladder. The membranous receptacle, which receives the urine ſecreted in the kidnies, is covered by a thin ſtratum of muſcular fibres, which ſerve the purpoſe of expelling the contained fluid, when it has accumulated to a certain quantity. This muſcular covering of the urinary bladder has been deſcribed as a muſcle by ſeveral anatomiſts, who have diſtinguiſhed it from its office, by the name of detruſor urinæ. For a more particular account of it, ſee KIDNEY, in which article the whole of the urinary organs will be conſidered.

DETTELBACH, in *Geography*, a ſmall town of Germany, in the grand duchy of Wurzburg, in the circle of Franconia. It is ſeated on the river Mayn. Its church is celebrated for a fine image of the Virgin.

DETTEZ, a town of France, in the department of the Saone and Loire, and diſtrict of Autun; 8 miles W.S.W. of Montcénis.

DETTINGEN, a village of Germany, in the circle of the Lower Rhine, belonging at that time to the elector of Mentz, is famous for the victory which the allied troops of Auſtria and England, led on by king George II. of Great Britain, gained in its vicinity over the French on the 16th of June 1743. It is ſituated on the Mayn, in the diſtrict of Seligenſtadt, between that town and Aſchaffenburg.

DETTOR, a river of N. Wales, which runs into the Tivy, in the county of Cardigan.

DETUNDA, in *Ancient Geography*, a town of Spain, in Bœtica, belonging to the Turduli. Ptolemy.

DEVA, a town of Arabia Felix. Ptolemy.

Deva, a river of ancient Britain, which is evidently the river Dee in Galloway, which falls into the ſea at Kirkcudbright.

Deva, called alſo *Deuna*, or *Deonna*, a place in the ſecond route of Antonine's Itinerary, between Condate and Bovium, in the country of the Cornavii, unqueſtionably ſituated where the city of Cheſter now ſtands; it was a place of great conſideration, a Roman colony, and the head-quarters of the 20th legion. This legion came into Britain in the reign of the emperor Claudius, and was employed in the conqueſt of this iſland, and in many important works and expeditions in different parts of it. Though the 20th legion continued more than two centuries in Britain, it ſeems to have left this country a conſiderable time before the final departure of the Romans. It is moſt probable that it was recalled about the end of the fourth, or beginning of the fifth century, when the continental provinces of the empire began to be much haraſſed by the incurſions of barbarous nations.

Deva, in *Geography*, a ſmall town of Spain, in Biſcay, in the province of Giupuzcoa. It is ſituated on the river of the ſame name, which forms a harbour in the bay of Biſcay, 36 miles S.E. of Bilbao, and 15 N. of Placentia. W. long. 3°. N. lat. 43° 30'.

Deva, a town of Tranſylvania; 10 miles W. of Millenbach.

DEVANA Texalorum, in *Ancient Geography*, a place of Britain, in the country of the Texali, near the eſtuary of the river Diva or Dee, now Old Aberdeen.

DEVAPORATION, in *Phyſics*, is a term uſed by way of contraſt to *evaporation*, which ſee. As heat ſeems to be the principal cauſe of evaporation, as well as of ſolution, and of fluidity in general, the privation of heat may be eſteemed the principal cauſe of devaporation; for, though the air may, by its own power of attraction, or by means of the electricity it may contain, diſſolve and ſuſpend a portion of water, as water diſſolves and ſuſpends a portion of ſalt; yet, by the application of cold, theſe are reſpectively precipitated; and, therefore, heat may be aſſumed as the immediate cauſe of theſe ſolutions. Beſides, water boils *in vacuo* with leſs heat; that is, it evaporates *in vacuo*, more rapidly or more eaſily than in the open air, and therefore the attractive power of the atmoſphere does not ſeem neceſſary to evaporation. When the barometer ſinks, whatever may be the cauſe, the lower ſtratum of air becomes expanded by its elaſticity, being releaſed from a part of the ſuper-incumbent preſſure, and, in conſequence of its expanſion, robs the vapour which it contains of its heat; whence that vapour becomes condenſed, and is precipitated in ſhowers; as is viſible in the receiver of an air-pump. There are, however, two curious circumſtances, relating to the devaporation of water. 1. That the deduction of a ſmall quantity of heat from a cloud or expanſe of vapour, compared with the quantity of heat which was neceſſary to raiſe that vapour from water, will evaporate the whole. This circumſtance is evident in the operation of common ſteam-engines, in which a ſmall jet of water, whoſe heat is often above 48 degrees, perpetually devaporates the ſteam raiſed by a comparatively very great quantity of heat under the boiler. This phenomenon may be thus explained; if a ſmall part of the quantity of vapour be ſuddenly condenſed, a vacuity takes place, and the contiguous walls of vapour expand themſelves into this vacuity; and thus a large area of vapour, perhaps of many miles in circumference, becomes more or leſs expanded; by this expanſion cold is produced, (that is, its capacity of receiving heat is increaſed,) and the whole is devaporated. Something ſimilar to this is often ſeen at the commencement of thunder-ſtorms; a ſmall black cloud at firſt appears, in a few minutes the whole heaven is covered with condenſing vapour, and the accumulation or eſcape of electric matter, ſeems to be rather the conſequence than the cauſe of this ſudden and general devaporation. A ſecond curious circumſtance of aerial devaporation is, that when the particles of aqueous vapour begin to approach each other by the diminution of their heat, they do not generate water exactly in proportion to ſuch diminution of heat; but the condenſation proceeds further, and not only a greater quantity of water is produced, but alſo a quantity of heat is ſet at liberty along with this exceſs of devaporation, and the atmoſphere becomes warmer than before the beginning of condenſation. This exceſs of devaporation beyond the cold which produced it is probably owing to the acquired momentum of the aqueous particles towards each other at the beginning of their condenſation, which carries them ſtill nearer each other: and to the ſmall moleculæ at firſt formed, poſſeſſing a greater attractive power over the uncondenſed vapour in their vicinity, and thus preſſing out more of the latent or combined heat. On this ſubject ſee Dr. Darwin's paper in Phil. Tranſ. vol. lxxxviii.

DEVASTAVIT, or Devastaverunt *bona teſtatoris*, a writ that lies againſt executors or adminiſtrators, for paying debts upon ſimple contract and legacies, before debts on bonds and ſpecialties, &c. for in this caſe they are as liable to action, as if they had ſquandered away the goods of the deceaſed, or converted them to their own uſe; and are compellable to pay ſuch debts by ſpecialty out of their own goods, to the value of what they ſo paid illegally. (Dyer, 232.) But if an executor pays debts upon ſimple contract, before he hath any notice of bonds, it is no devaſtavit; and regularly this notice is by an action commenced againſt him, for the law doth not oblige him to take notice of it himſelf, nor of a judgment againſt his teſtator; becauſe he is not privy to acts done either by or againſt him. 1 Mod. 175. 1 Lev. 115.

Executors keeping the goods of the deceaſed in their hands, and not paying the teſtator's debts; or ſelling them, and not paying off debts, &c., or not obſerving the law which directs them in the management thereof; or doing any thing by negligence or fraud, whereby the eſtate of the deceaſed is miſemployed, are guilty of a devaſtavit, or waſte; and they ſhall be charged for ſo much *de bonis propriis*, as if for their own debt. (8 Rep. 133.) But the fraud or negligence of one executor is not chargeable on the reſt, where there are ſeveral executors. 1 Rol. Abr. 929. See Debt and Executor.

DEVAUX, John, in *Biography*, a native of Paris, born in the year 1610, was educated to the practice of ſurgery, which he appears to have followed to a late period, and with reputation, as we find him inveſted, for the third time, with the preſidency, or deanſhip, of the company of ſurgeons, at the time of his death, which happened in September 1695,

when

when he was in the 85th year of his age. This account we have from his ſon, alſo named John, who ſucceeded to the honourable ſtation, held by his father. It does not appear that the father had publiſhed, or that he left any thing written on the ſubject of medicine, but the deficiency was abundantly ſupplied by the ſon, who beſides ſome not inconſiderable original works, introduced to his countrymen, as editor, or tranſlator, a great number of medical works, written by foreigners. Among the tranſlations, are "Allen's Synopſis Medicinæ Practicæ;" "Harris de Morbis Infantum;" "Cockburne de Gonorhœa;" and "Friend's Emmenologia:" alſo "Epitomes of Anatomy," by Heiſter; and "Dionis. Saviard's Chirurgical Obſervations;" "Boerhaave on the powers of Medicine;" "La Motte's Treatiſe of Midwifery." His original works are, "Le Medicin de ſoi-meme, ou l'art de ſe conſerver la ſante, par inſtinct." Leid. 1682, 12mo. Diſeaſes are cauſed, he ſays, by repletion in the veſſels, and by corruption of the contents of the bowels. They are to be cured by bleeding, by emptying the bowels, and by abſtinence, to prevent a re-accumulation. He cenſures the phyſicians for their general want of ſucceſs in practice, and ſhews them that illiterate countrymen frequently effect cures they are incapable of performing. "Art de faire les rapports en Chirurgie, par M. D. Prevot de la Comp." Paris, 1727. Giving rules for detecting the cauſe of death in perſons who have been ſtrangulated, poiſoned, &c. Both this and the former works have gone through ſeveral editions.

DEUBACH, in *Geography*, a village of Germany, in the duchy of Saxe-Gotha, famous for its brooms, baſkets, and hampers, with which it carries on a conſiderable trade.

DEUCALEDONII, or CALEDONII, in *Ancient Geography*, a people who inhabited the northern part of the iſle of Albion; called by Ammianus Marcellinus *Dicaledones*. See CALEDONIA.

DEUCALION, a name given by Strabo to an iſland, which he places over-againſt a promontory of Theſſaly, in the environs of the Maliac gulf.

DEUCALION, in *Mythology*, was the ſon of Prometheus, who married Pyrrha, the daughter of his uncle Epimetheus. Prometheus, it is ſaid, had been baniſhed into Scythia, to the confines of Caucaſus, during the wars of the Titan princes. His ſon Deucalion, weary of this melancholy retreat, came and ſettled in Theſſaly, in the vicinity of Phthia, or rather, according to the Parian marbles, in Lycoria, near Parnaſſus. The era of his arrival is marked in the ſame chronicle, at the 9th year of the reign of Cecrops at Athens, which commenced, according to the Arundelian marbles, in the year 1582 B. C., or according to the account given by Euſebius, in the year 1556 B. C. or 780 years before the 1ſt Olympiad. Deucalion, it is ſaid, not contenting himſelf with the petty ſtates which he had ſeized upon, made war upon his neighbours, and made himſelf maſter of the Lower Theſſaly, near the river Peneus; the name of the province at that time was Phthiotis, from Phthius of Arcadia, who had ſeized upon it 160 years before, according to Pauſanias (in Arcad.) Moſt authors are of opinion that the deluge which happened in the reign of this prince, about the year 1503 B.C., according to Euſebius's account, or, according to the marbles 26 years earlier, was occaſioned by the river Peneus, whoſe courſe was probably ſtopped by ſome earthquakes between mount Oſſa and Olympus, where is the mouth of that river, through which it diſcharges itſelf into the ſea, with the accumulation of water furniſhed by five other rivers. This overflow, as it is ſaid, together with a vaſt quantity of rain that fell that year, laid all Theſſaly, which is a low country, under water. (See Herodotus, l. i.) Some time after, the waters having retired, the country was very ſoon re-peopled. When the waters were aſſuaged, Deucalion, according to the Parian Chronicle, went to Athens, where, in gratitude to the gods for having preſerved him from the general inundation of the country, he offered ſolemn ſacrifices to Jupiter, in a temple which he built to his honour, and which was ſtill ſubſiſting in the time of Piſiſtratus, who, at a great expence, rebuilt it.

Some have ſuppoſed that Deucalion, whom the Greeks have repreſented under a variety of characters, and concerning whom their poets have given many fabulous accounts, was the ſame with the patriarch Noah; and that Deucalion's flood in Theſſaly, as well as that of Ogyges in Attica, and of Prometheus in Egypt, were the ſame with that of Noah, recorded in Scripture. Diodorus Siculus expreſsly ſays, that, in the deluge which happened in the time of Deucalion, almoſt all fleſh died. Apollodorus having mentioned Deucalion εν-λαρνακι, *conſigned to an ark*, takes notice, upon his quitting it, of his offering up an immediate ſacrifice, Δι-φυζιω, *to the god who delivered him*. As he was the father of all mankind, the ancients have given him great dignity and univerſal monarchy; though ſometimes he is reduced to a petty king of Theſſaly. Apollonius Rhodius makes him a native of Greece, and the ſon of Prometheus. We may learn, however, from their confuſed hiſtory, that the perſon repreſented was the firſt of men, through whom religious rights were renewed, cities built, and civil policy eſtabliſhed in the world: none of which circumſtances are applicable to any king of Greece. Philo aſſures us, that the Grecians call the perſon Deucalion, but the Chaldæans ſtyle him Noe, in whoſe time there happened the great eruption of waters. But as Lucian has given us the moſt particular hiſtory of the deluge, and that which comes neareſt to the account given by Moſes; and as he was a native of Samoſata, a city of Commagene upon the Euphrates, a part of the world where memorials of the deluge were particularly preſerved, and where an obvious reference to that hiſtory may be obſerved in the rites and worſhip of the country, we ſhall terminate this article with an extract of what he ſays on the ſubject.

Having deſcribed Noah under the name of Deucalion, he ſays, that the preſent race of mankind are different from thoſe who firſt exiſted; for thoſe of the antediluvian world were all deſtroyed. The preſent world is peopled from the ſons of Deucalion; having increaſed to ſo great a number from one perſon. In reſpect to the former brood, they were men of violence, and lawleſs in their dealings. They regarded not oaths, nor obſerved the rites of hoſpitality, nor ſhewed mercy to thoſe who ſued for it. On this account they were doomed to deſtruction: and for this purpoſe there was a mighty eruption of waters from the earth, attended with heavy ſhowers from above; ſo that the rivers ſwelled, and the ſea overflowed, till the whole earth was covered with a flood, and all fleſh drowned. Deucalion alone was preſerved to re-people the world. This mercy was ſhewn to him on account of his juſtice and piety. His preſervation was effected in this manner: he put all his family, both his ſons and their wives, into a vaſt ark which he had provided, and he went into it himſelf. At the ſame time animals of every ſpecies, boars, horſes, lions, ſerpents, whatever lived upon the face of the earth, followed him by pairs; all which he received into the ark, and experienced no evil from them: for there prevailed a wonderful harmony throughout by the immediate influence of the Deity. Thus were they wafted with him, as long as the flood endured.

After this, he proceeds to mention that, upon the diſappearing of the waters, Deucalion went forth from the ark, and raiſed an altar to God. Diod. Sic. lib. i. p. 10. Apollod. lib. i. p. 20. Apollon. Rhod. lib. iii. v. 1085. Philo Jud. de Præmio & Pœna, vol. ii. p. 412. Lucian de Dea Syria, vol. ii. p. 882.

Dr. Bryant produces a variety of monuments, that bear an obvious reference to the deluge, in the Gentile hiſtory, beſides this account of Deucalion and his flood. Analyſis of Ancient Mythology, vol. ii. p. 193—250. See DELUGE.

DEVELTO, or ZAGORIA, in *Geography*, a town of European Turkey, in Bulgaria, the ſee of a Greek archbiſhop, near the Black ſea; 59 miles N.E. of Adrianople, and 106 N.N.W. of Conſtantinople. N. lat. 42° 25′. E. long. 27° 22′.

DEUELTUS, or DEUELTON, in *Ancient Geography*, a town in the interior of Thrace, towards the Euxine ſea, not far to the weſt of Apollonia, on the border of a lake. It became a Roman colony under Veſpaſian, who fixed his veterans there; from this prince it took the name of Flavia, as it is found upon medals.

DEVENERUNT, in *Law*, a writ anciently directed to the eſcheator, on the death of the heir of a tenant of the king holding *in capite*, within age, and in the king's cuſtody; commanding the eſcheator, to enquire, upon the oaths of good and lawful men, what lands and tenements, by the death of the tenant, come to the king (Dyer 360.) This writ is now diſuſed.

DEVENISH, in *Geography*, an iſland in Lough Erne, in the county of Fermanagh, Ireland, which is remarkable for fine ſcenery. There are in this iſland a round tower, and the ruins of a priory, which Ledwich ſuppoſes to have belonged originally to the Culdees, and which afterwards under the Auguſtinians acquired great poſſeſſions. It is a few miles from Enniſkillen. Ledwich.

DEVENTER, HENRY, in *Biography*, a celebrated accoucheur, was born at Deventer, in the province of Over-Yſſel, in Holland, towards the end of the 17th century. Though ſkilled in every branch of medicine, and honoured with the dignity of doctor in that faculty, he was principally employed in ſurgery, and in the latter part of his life he almoſt entirely confined himſelf to the practice of midwifery, in which art he made conſiderable improvements. He acquired alſo no ſmall ſhare of fame by his various mechanical inventions, for aſſiſting in preventing and curing deformities of the body, in young ſubjects. In that capacity he was repeatedly ſent for to Denmark, whence he drew a conſiderable revenue. His knowledge of mechanics did not, however, prevent his obſerving that much miſchief was done by the too frequent uſe of inſtruments in midwifery.

The greateſt difficulty to the birth of the child occurred, according to his doctrine, from the uterus being placed obliquely in the pelvis. In conſequence of this poſition, the pains or contractions of that viſcus forced the preſenting part of the child againſt one ſide of the collum uteri, inſtead of preſſing it immediately into its orifice. This defect he attempted to remedy, by paſſing his hand into the uterus, and bringing the vertex of the head of the fœtus into the opening or mouth of the womb. When the pelvis of the woman was too ſtraight, he often remedied the evil, by puſhing back the os coxygis with his hand. This, however, muſt be done very delicately, or abſceſſes in the part, or incurable lameneſs, may be produced. Deventer had probably met with accidents of the kind, as in the latter part of his life he admitted the neceſſity of ſometimes opening the head of the child, and then drawing it away with the crotchet. When an arm of the child preſented, he paſſed his hand into the uterus, and brought it away by the feet, without firſt twiſting off the preſenting arm, as had been recommended and practiſed by former writers on the ſubject. He taught his pupils to diſtinguiſh ſpurious from true labour pains, and to quiet the ſpurious pains, by emptying the bowels, by glyſters and mild eccoprotics, and by giving one or more of his anodyne or opiate pills; the compoſition of which he for a long time kept ſecret. Theſe were ſerious improvements in the art, and gave him a decided preference over Mauriceau, his almoſt immediate precurſor. Satisfied with the principles on which his practice was founded, he publiſhed, in 1701, "Operationes Chirurgicæ novum lumen exhibentes, obſtetricantibus," Leiden, 4to. It had been before publiſhed, *viz.* in 1696, in his native language. This was followed by a ſecond part, in 1724, 4to., "Ulterius examen partuum difficilium, Lapis Lydius obſtetricum, et de neceſſaria cadaverum inciſione." The two parts were publiſhed together, much improved in 1733, but the work had already been tranſlated and publiſhed in moſt of the countries in Europe. How long the author continued to live after the emiſſion of this improved edition is not known.

He had often, he ſays, been required to let the world know, by advertiſement, what kind of defects in the form of the body he was able to cure or relieve, but had not thought it expedient to do ſo; theſe he has enumerated and deſcribed at the end of the work. They are 22 in number; among them are the following: When the head, from a contraction of the tendons, fell on one of the ſhoulders, he enabled the party to hold his head erect. On the other hand, when a child came into the world club-footed, ſo that it could only touch the ground with its ankles, he completely, he ſays, cured the defect, and he was ſo ſure of his principles, that he required no part of his ſtipulated pay, until the cure was effected. Some time after his death, *viz.* in 1739, a poſthumous work was publiſhed on the rickets, in his native language. Haller ſpeaks favourably of it, and has given a brief analyſis of its contents, by which it appears to contain ſome uſeful practical obſervations. Haller. Bib. Chir.

DEVENTER, in Latin *Daventria*, or *Devonturum*, in *Geography*, a conſiderable and populous town of Holland, chief place of the department of Over Yſſel, ſituated on the river Yſſel, over which it has a bridge of boats. It brews an excellent beer, is famous for its cakes, and has an academy, or *Gymnaſium illuſtre*, and a canon foundery. Anciently it was a free imperial Hanſeatic town. Deventer is the native city of James Gronovius, Henry Deventer, and Everard Bronchorſt. It is 12 miles N. of Zutphen, 66 E. of Amſterdam, 51 W. of Benthem, in E. long. 5° 8′. N. lat. 52° 15′.

DEVEREUX, ROBERT, in *Biography*, ſecond earl of Eſſex, a perſon of great diſtinction in the reign of queen Elizabeth, was born at Netherwood, in Herefordſhire, in the year 1567. His father, Walter, earl of Eſſex, dying when Robert was but ten years old, left him to the guardianſhip of Cecil lord Burleigh. Two years after this event, he was ſent to Trinity College, Cambridge, where he was put under the tuition of Dr. Whitgift, afterwards archbiſhop of Canterbury. In his ſeventeenth year he was introduced at court, and in 1585 he accompanied the earl of Leiceſter, who had married his mother, to Holland, where he ſo much diſtinguiſhed himſelf at the battle of Zutphen, as to be created a knight banneret in the camp. Upon his return home, he was made maſter of the horſe in the place of the earl of Leiceſter, who was advanced to the poſt of high ſteward; and in 1588 he accompanied the queen to Tilbury, to reſiſt the Spaniſh invaſion, and was there appointed maſter of the horſe,

horſe, and was decorated with the order of the garter. Theſe high honours rendered him haughty and preſumptuous, qualities which led him into ſerious difficulties. In 1589, he gave proof of his enterprizing diſpoſition by joining, without leave, an expedition under the conduct of ſir John Norris and ſir Francis Drake, for the purpoſe of reſtoring Don Antonio to the throne of Portugal. In this buſineſs the earl of Eſſex had an opportunity of exhibiting his courage: while ſkirmiſhing in the neighbourhood of Liſbon, he challenged, by the ſound of the trumpet, the governor, or any perſon of equal quality with himſelf, to ſingle combat. Elizabeth, at firſt, expreſſed herſelf very indignantly at the conduct of the earl for leaving the kingdom without permiſſion; but ſhe was ſoon reconciled, and beſtowed upon him ſignal marks of favour in various grants of land of conſiderable value. Upon the death of his father-in-law a new field ſeemed to be opened to his ambition: he made himſelf the head of the Puritan party, and married privately the widow of ſir Phillip Sydney, with which the queen was diſpleaſed: ſhe, however, very ſoon forgave him, and ſent him with a body of 4000 men to the aſſiſtance of Henry IV. king of France, then fighting againſt the league. He was ſoon after created privy counſellor, and, in 1596, was appointed joint commander with lord Howard in an expedition to the coaſt of Spain. In this expedition, which makes a conſiderable figure in Engliſh hiſtory, lord Eſſex diſtinguiſhed himſelf and acquired much popularity. At court he had many enemies, who were jealous of his fame, and envious of the honours which he acquired by his valour and heroiſm: theſe attempted to injure him in the ſovereign's eſtimation, but without effect; ſhe made him maſter of the ordnance; and when Ireland was threatened with a Spaniſh invaſion, ſhe appointed him to the chief command of a fleet equipped for the purpoſe. In this affair little glory was acquired by any concerned in it; and lord Eſſex was highly offended by the conduct of ſome of his brother officers; he was, however, ſoothed by his elevation to the dignity of earl marſhal of England. When peace with Spain was propoſed, he would liſten to no terms of accommodation; in debating the ſubject in council he excited the anger of lord Burleigh, who drew out a prayer-book from which he read, addreſſing himſelf to lord Eſſex, "Men of blood ſhall not live out half their days." On this occaſion he felt it neceſſary to vindicate himſelf from the opprobrium of being thought inimical to peace; he accordingly drew up an eloquent apology on the ſubject. On the death of lord Burleigh, he was appointed to the chancellorſhip of Cambridge. About this period a private council was called to determine upon a proper perſon to be ſent governor of Ireland. Eſſex and the queen were at variance as to the fitteſt man. The diſpute was warm, and the miniſter, unable to perſuade his ſovereign, contemptuouſly turned his back upon her. Provoked at his inſolence, ſhe bade him retire and be hanged, accompanying her command with a blow on the face. Eſſex, thrown off his guard, claſped his ſword, ſwearing the affront was ſuch as he could not and would not put up with. He withdrew in anger, and for ſome time ſeemed to ſet at defiance the queen's diſpleaſure, but at length he ſubmitted and was reſtored to favour. A renewal of troubles in Ireland required a new governor, and Eſſex was appointed to this office, which he accepted, though probably much againſt his inclination, for in a letter which he wrote to the queen before his departure, he aſks, "From a mind delighting in ſorrow, from ſpirits waſted with paſſion, from a heart torn in pieces with care, grief, and travel; from a man that hateth himſelf, and all things elſe that keep him alive; what ſervice can your majeſty expect, ſince any ſervice paſt deſerves no more than baniſhment and proſcription to the curſedeſt of all iſlands?" He however went, but his ſucceſs did not correſpond with the expectations that had been formed by the queen, and that had indeed been excited by his own letters; he reſolved to return to vindicate his conduct. Arriving unexpectedly, and in defiance of the commands under which he ought to have acted, he threw himſelf at the feet of his ſovereign, who at firſt ſeemed to receive him with more favour than he had anticipated; but he was ſoon after treated with much ſeverity, committed to private cuſtody, examined with rigour before the council, and ſuſpended from almoſt all his employments. He endeavoured to bear the reverſe of fortune with patience and fortitude, but his feelings and paſſions overcame his reaſon, and he ſunk into an alarming illneſs; during this he had the ſatisfaction of being favoured with ſome extraordinary tokens of the queen's remaining regard; and he might ſtill have reinſtated himſelf in her favour; but, being ſet at liberty, and liſtening to the dangerous counſels of Cuffe, who had been his ſecretary in Ireland, he ſeemed anxious to take revenge on his enemies. A conſpiracy was formed againſt the perſon of the ſovereign, which being diſcovered, lord Eſſex and others were apprehended under a charge of high treaſon. He and his chief adherent, the earl of Southampton, were committed to the Tower, and were afterwards tried by a jury of their peers, and were found guilty of the crimes with which they were charged. Sentence was pronounced, and the earl of Eſſex heard it with compoſure as a man prepared for his fate. The queen was long before ſhe could be brought to ſign the fatal warrant for the execution of her once favourite miniſter: ſhe waited for an application for mercy, and conſtrued his ſilence to an obſtinacy not to be forgiven. He was executed on the 25th of February 1601. He met his death not with any apparent anxiety or terror, but with a humility and contrition which his religion inſpired. He ſuffered in his thirty-fourth year. His character was adorned with many ſplendid virtues: he was brave, open, and affectionate; but it muſt be admitted that his conduct was often marked with raſhneſs, violence, and precipitancy. He was a friend and the patron of literature. His memory has been always popular, and his unfortunate end has been the ſubject of four different tragedies. The queen, after the unfortunate death of her favourite, gave herſelf up to melancholy. She had given him a ring during the height of his favour, as a pledge, on the return of which ſhe promiſed to pardon any offence he might commit. This ring, it is believed, the unhappy man entruſted to his relation the counteſs of Nottingham, who was not ſuffered by her huſband, the capital enemy of Eſſex, to deliver it. The counteſs, on her death-bed, confeſſed the fact to the queen, imploring her forgiveneſs, of which ſhe had not the ſmalleſt chance. "God may forgive you," exclaimed the indignant ſovereign, "but I never can." Biog. Brit.

Devereux, Robert, ſon of the preceding, was born in 1592, and was of courſe old enough at his father's death to feel his unfortunate ſituation. He was at that time, or very ſoon after, entered at Merton College, Oxford, under the particular care of the warden, Henry Saville, who had been his father's intimate friend. King James, almoſt immediately upon his ſucceſſion to the throne, reſtored the youth to all his hereditary honours. He was already in poſſeſſion of his father's high ſpirit, of which he gave a ſufficient indication in a quarrel which he had with prince Henry. Some diſpute aroſe between them at a game at tennis; the prince called his companion the ſon of a traitor, who retaliated by giving him a ſevere blow with his racket; and the king was

obliged to interfere to reſtore peace. At the age of fourteen this young man was betrothed to lady Frances Howard, who was ſtill younger than himſelf. The earl immediately ſet out on his travels, and during his abſence the affections of his young wife were eſtranged from him, and fixed upon the king's favourite Carr, afterwards earl of Somerſet. The conſequence was a ſuit inſtituted againſt the huſband for impotency, in which, to the diſgrace of the age, the king interfered, and which ended in a divorce. The earl of Eſſex, feeling himſelf diſgraced by the ſentence, retired to his country ſeat, and ſpent ſome years in rural ſports and amuſements. In the year 1620, being wearied of a ſtate of inaction, he joined the earl of Oxford in a military expedition to the Palatinate, where they ſerved with companies of their own raiſing under ſir Horatio Vere. In the following year they ſerved in Holland, under prince Maurice. In the courſe of the winter they returned to England, and lord Eſſex appeared in the ranks of the oppoſition in parliament. On this account he was not favourably received at court, which was the mean of attaching him the more cloſely to foreign ſervice. He commanded a regiment, raiſed in England for the United States, in 1624, and though nothing very important was atchieved by the Engliſh auxiliaries, yet the earl of Eſſex acquired experience, and diſtinguiſhed himſelf among the nobility of the time. On the acceſſion of Charles I. he was employed as vice-admiral in an expedition againſt Spain, which proved unſucceſsful. In 1626 he made another campaign in the Low Countries, and ſhortly after he married the daughter of ſir William Paulet, but his lady's conduct cauſed a divorce within two years. He now reſolved to give himſelf up entirely to public life: he courted popularity, and made friends among the officers of the army and the Puritan miniſters. He was, however, employed by the king in various important ſervices; but when the raſh meaſures of government forced the ſovereign and his court from the metropolis, lord Eſſex pleaded in excuſe his obligation to attend in his place as peer of the realm; he was accordingly deprived of all his employments. This ſtep fixed him in oppoſition to the king, and in July 1642 he accepted the poſt of general of the parliamentary army: he oppoſed the king in perſon at Edge-hill, where the victory was ſo indeciſive, that each party claimed it as his own. After this he was ſucceſsful in ſome few inſtances, but in other important truſts he did little to recommend him to the perſons in whoſe intereſts he was employed. He was, however, treated with external reſpect; but the ſelf-denying ordinance (ſee CROMWELL) threw him entirely out of the command: he reſigned his commiſſion, but not without viſible marks of diſcontent. Unwilling to loſe him altogether, the parliament voted that he ſhould be raiſed to a dukedom, and be allowed ten thouſand pounds *per annum*, to ſupport his new dignity. Neither of theſe were realized, and the earl died ſuddenly, September 14, 1646. Parliament directed a public funeral for him, which was performed with great ſolemnity in the following month, at Weſtminſter Abbey. Such was the end of this nobleman, whoſe conduct as a warrior will be again referred to in ſeveral hiſtorical articles of this work. With him the title of Eſſex became extinct. Biog. Brit.

DEVERON, in *Geography*, a river of Scotland, which runs into the Frith of Murray, at Banff.

DEVERRA, in *Mythology*, the tutelary goddeſs of children.

DEVERRONA, the goddeſs who preſided over the reaping of the crop or productions of the ſoil.

DEVESE, LA, in *Geography*, a ſmall town of France, in the department of Gers, near Mirande; 24 miles S.W. of Auch.

DEVEST, DEVESTIRE, in *Feudal Writers*, is uſed for the oppoſite to inveſting. *Inveſtire* ſignifies *poſſeſſionem feudi tradere*. On the contrary, *deveſtire* is *poſſeſſionem auferre*. Feud. lib. i. c. 7. Cowell.

DEVIAC, in *Geography*, a town of France, in the department of the Charente, and diſtrict of Barbezieux; 15 miles S. of Angouleſme.

DEVIATAIA, a river of Siberia, which runs into the Oſenoka. N. lat. 62° 25′. E. long. 149° 34′.

DEVIATION, in the *Old Aſtronomy*, a motion of the deferent, or eccentric, whereby it advances to, or recedes from, the ecliptic. See DEFERENT.

The greateſt deviation of a planet is equal to the inclination of its orbit to the plane of the ecliptic. See INCLINATION *of a Planet*.

DEVIATION *of a falling Body*. The queſtion of the diurnal revolution of the earth has long ſince ceaſed to be a diſputed point. Nevertheleſs, an experimental demonſtration of the fact can never fail to merit attention.

It has been generally admitted, that a heavy body, deſcending from a conſiderable height, ſhould not fall exactly on the point perpendicularly under it, but ſhould deviate a very ſmall quantity towards the eaſt.

Let the point A, and the point B, directly under it, (*Plate* IX. *Aſtronomy, fig.* 63.) be ſuppoſed to have a common motion in the direction A *c*, or B C, parallel to it, A *c* being equal to B C. If a body be let fall from A, it will fall on the point C, directly under *c*; but if A has a greater motion, previous to its deſcent, as A *c′*, it will then arrive at ſome point C′ forwarder than C, or more diſtant from B.

M. Guglielmini publiſhed, in 1792, ſome very curious experiments on this ſubject, made at Bologna in a work entitled "De diurno terræ motu experimentis confirmato opuſculum." The height was 241 French feet; and he found a deviation of 8 lines towards the eaſt.

Similar experiments have been repeated lately by M. Henzenberg at Hamburgh.

From a height of 235 feet, he found the deviation 4 lines.

In each of the above experiments, a ſmall deviation was obſerved towards the ſouth, the cauſe of which it is not eaſy to explain.

Laplace, who has inveſtigated the theory of this phenomenon, gives the following reſult:

Let b be the height;

g double the height a body deſcends in one ſecond;

n the angle of rotation of the earth in one ſecond;

θ the co-lat. of the place.

The deviation towards the eaſt will be equal to $\frac{2}{3} n b$ ſin. $\theta \sqrt{\frac{2b}{g}}$.

This, in M. Henzenberg's experiment, gives 3.9 lines.

In M. Guglielmini's the obſerved deviation was nearly double that indicated by the theory.

DEVIATION, in *Marine Inſurances*, denotes a voluntary departure, without any neceſſity, from the uſual courſe of the voyage inſured. From the moment this happens, the voyage is changed, the contract is determined, and the inſurer is diſcharged from all ſubſequent reſponſibility. By the terms of contract, the inſurer only runs the riſk of the voyage agreed upon, and of no other: and it is, therefore a condition neceſſarily implied in the policy, that the ſhip ſhall proceed by the ſhorteſt and ſafeſt courſe to her port

of

of deſtination, and on no account to deviate from that courſe, but in caſes of neceſſity.

In determining what ſhall amount to a deviation that will diſcharge the inſurers, it ſhould be conſidered, that the courſe of the voyage does not mean the neareſt poſſible way, but the uſual and regular courſe. Stopping at certain places in the voyage, though out of the direct line, is no deviation, if it be cuſtomary ſo to do. The effect of a deviation is not to *vitiate* or *avoid* the policy, but only to determine it from the time of the deviation, and to diſcharge the inſurer from all ſubſequent reſponſibility; who is, nevertheleſs, entitled to retain the whole premium. The contract, however, is determined by the deviation, though the ſhip ſhould afterwards reſume her proper courſe, and be in a condition to complete the voyage. The true reaſon why a deviation diſcharges the inſurer, is not the increaſe of the riſk; but that the party contracting has, without neceſſity, ſubſtituted another voyage for that which was inſured. However, if a deviation can be juſtified by neceſſity, the inſurer will ſtill remain liable. One general principle pervades all the caſes on this point; namely, that if the captain, in departing from the uſual courſe of the voyage, acts fairly and *bonâ fide*, and according to the beſt of his judgment, for the benefit of all parties concerned, and has no other view but to conduct the ſhip and cargo, by the ſafeſt and ſhorteſt courſe, to her port of deſtination; what he does is within the ſpirit of the contract, and the voyage will ſtill be protected by it. In all caſes, therefore, in order to determine whether a departure from the direct courſe of the voyage inſured amounts to a deviation that will diſcharge the inſurer, it will be proper to attend to the motive, end, and conſequences of the act, as the true criterion of judgment. The caſes of neceſſity, which are moſt frequently adduced to juſtify a departure from the direct courſe of the voyage inſured, are ſtreſs of weather, want of neceſſary repair, joining convoy, eſcaping from, or avoiding an enemy, and mutiny of the crew. From an examination of the moſt approved authorities for determining caſes of this kind, it is inferred, that nothing will juſtify a deviation but a real and imperious neceſſity; and that the extent of the deviation muſt be juſtified by the degree of that neceſſity. Beſides, if a ſhip be compelled by any neceſſity to deviate from the uſual and regular courſe of the voyage, ſhe muſt purſue the new voyage of neceſſity ſo far as to get to her port of deſtination by the ſhorteſt and ſafeſt courſe ſhe can take; and any wilful departure from the direct courſe of this voyage, or any unneceſſary delay, will be a new deviation, which will diſcharge the under-writers in like manner as if it had been a deviation from the original voyage. Marſhall's Treatiſe on the Law of Inſurance, vol. ii. p. 392, &c.

DEVICE, in *Printing*. See DEVISE.

DEVICZA, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 48 miles S.S.W. of Sandomirz.

DEVIL, DIABOLUS, an evil angel; one of thoſe celeſtial ſpirits, ſaid to have been caſt down from heaven, for pretending to equal himſelf with God.

The word is formed from the French *diable*, of the Latin *diabolus*, which comes from the Greek διαβολος, which, in its ordinary acceptation, ſignifies *calumniator, traducer*, or *falſe accuſer*, from the verb διαβαλλειν, *to calumniate, &c.*; or from the ancient Britiſh *diafol*.

Dr. Campbell, in his "Preliminary Diſſertations to the Four Goſpels," (vol. i. p. 182.) obſerves, that, though the word is ſometimes, both in the Old Teſtament and the New, applied to men and women of this character, it is, by way of eminence, employed to denote that apoſtate angel, who is exhibited to us, particularly in the New Teſtament, as the great enemy of God and man. In the two firſt chapters of Job, it is the word in the Septuagint, by which the Hebrew שָׂטָן, *Satan*, or *adverſary*, is tranſlated. Indeed, the Hebrew word, in this application, as well as the Greek, has been naturalized, ſays this writer, in moſt modern languages. Thus we ſay, indifferently, *the devil*, or *Satan*; only the latter has more the appearance of a proper name, as it is not attended with the article. There is, however, this difference between the import of ſuch terms, as occuring in their native tongues, and as modernized in tranſlations. In the former, they always retain ſomewhat of their primitive meaning, and, beſide indicating a particular being, or claſs of beings, they are of the nature of appellatives, and mark a ſpecial character, or note of diſtinction in ſuch beings. Whereas, when thus Latinized or Engliſhed, they anſwer ſolely the firſt of theſe uſes, as they come nearer the nature of proper names. Διαβολος, as Dr. Campbell has obſerved, is ſometimes applied to human beings; but nothing is more eaſy than to diſtinguiſh this application from the more frequent application to the arch-apoſtate. One mark of diſtinction is, that, in this laſt uſe of the term, it is never found in the plural. When the plural is uſed, the context always ſhews that it refers to human beings, and not to fallen angels. It occurs in the plural only thrice, and only in the epiſtles of St. Paul. 1 Tim. iii. 11. 2 Tim. iii. 3. Tit. ii. 3. Another criterion, he ſays, whereby the application of this word to the prince of darkneſs may be diſcovered, is its being attended with the article. The term almoſt invariably, with a few exceptions, is ὁ διαβολος. The excepted inſtances occur in the addreſs of Paul to Elymas the ſorcerer, Acts. xiii. 10; and that of our Lord to the Phariſees, John viii. 4. The more doubtful caſes are thoſe in 1 Pet. v. 8, and Rev. xx. 2. Theſe, ſays Dr. Campbell, are all the examples in which the word, though uſed indefinitely or without the article, evidently denotes our ſpiritual and ancient enemy; and the examples, as he adds, in which it occurs in this ſenſe, with the article, are too numerous to be recited. Thoſe who maintain the doctrine of a devil and of his agency, and the opinion of his being and influence has for a long time and very generally prevailed, ſuppoſe that there are various orders of evil angels, united under one head, who from the malignity of his nature is called *Satan*, or the *devil*. In proof of the exiſtence and influence of theſe inveterate enemies of God and of mankind, and of their original apoſtacy and rebellion, and of their ſubſequent influence over mankind, they refer to the hiſtory of the fall of our firſt parents, and to a variety of paſſages in the ſacred writings. See Matt. iv. 5—8; xii. 24. 28; xxv. 41. Epheſ. ii. 2; vi. 12. Col. ii. 15. Jude, v. 6. Rev. xii. 7. Theſe inviſible beings, it is ſaid, urged by a principle of enmity to God, and envy and malice againſt mankind, do their utmoſt to ſeduce men into ſin; and for that purpoſe are employed in ſtudying men's tempers, and making obſervations on the various circumſtances and occurrences of their lives. (1 Chron. xxi. 1. Zech. iii. 1, 2. Matt. xiii. 19. Luke, xxii. 31. John, viii. 44; xiii. 20. 22. Acts, v. 3. 2 Cor. ii. 11; iv. 4; xi. 3, 14, 15. Eph. ii. 2; vi. 11, 12, 16. 1 Theſſ. iii. 5. 2 Theſſ. ii. 9, 10, 18. 1 Pet. v. 8.)

Theſe malignant ſpirits, it is ſaid, are made uſe of as the inſtruments of divine Providence, to inflict calamities on the children of men; whilſt their malicious attempts are overruled by the ſuperior wiſdom and goodneſs of God, to anſwer the purpoſes of his government. (Luke, xiii. 16. 1 Cor. v. 5. Job, i. 2. 1 Tim. i. 20. Heb. ii. 14, 15.) They ſometimes, as the advocates of this opinion maintain, carry on their attempts in a ſecret and inviſible manner; and they

they ſometimes interpoſe more openly and without diſguiſe, or at leaſt have formerly been permitted to do ſo; particularly in the inſtances of dæmoniacal poſſeſſions, oracles, magic, witchcraft, and violent ſuggeſtions, and impulſes. It has alſo been an opinion generally received, that the devil has in ſome caſes entered into the bodies of men, and afflicted them ſeverely, by his ſupernatural agency. And even thoſe, who have rejected all ſtories of magical operations, performed by a combination with the infernal ſpirits, or of diabolical appearances; as being either the dreams of a diſordered imagination, the contrivance of art, or the vain fictions of thoſe who aimed at impoſing upon mankind; have nevertheleſs maintained, that Satan appeared in a viſible form to Chriſt, and that he animated the body of a ſerpent in the firſt temptation. From the ſeveral paſſages and facts above adduced, it has been inferred by the advocates of dæmoniſm, that the devils are beings of great power and knowledge; and that the purpoſes to which they ſeem to have interpoſed have generally been ſo malignant, as ſufficiently to prove they are evil dæmons, and as ſuch to be denounced and deteſted: and ſuch appearances, where Chriſtianity is known, ſhould be conſidered as confirming rather than weakening it: ſince the exiſtence, power, and malice of Satan conſtitute ſo great a part of the Chriſtian ſcheme. Where the goſpel is unknown, natural religion might teach men that there is a ſovereign almighty being of the moſt benevolent nature, and conſequently that theſe miſchievous beings were to be deteſted as his enemies, whatever power they might have, from which he would not fail to protect them who ſhould faithfully ſerve him. (See 2 Theſſ. ii. 9. 12.)

On the other hand, many objections have been alleged againſt the empire and agency aſcribed to the devil; and ſome have even denied his exiſtence, as well as his interference in the concerns and influence on the minds of men. Accordingly, it has been argued that we find no mention of the word devil in the Old Teſtament; but only of Satan, nor do we meet with the word devil in any heathen authors, in the ſignification attached to it among Chriſtians; that is, as a creature revolted from God: their theology went no farther than to evil genii or dæmons, who haraſſed and perſecuted mankind. Thus the Chaldæans believed both a good principle, and an evil principle, which was an enemy of mankind. See DÆMONS, and DÆMONIACS.

It has alſo been urged, that the agency of a being altogether malevolent, who is to every practical purpoſe omnipreſent and omniſcient, and endowed with formidable and indefinite powers, whoſe ſole employment is to do miſchief, and to tempt men to ſin, implies ſuch a reflection upon the wiſdom and benevolence of the Supreme Sovereign, that nothing ſhort of the moſt deciſive evidence can eſtabliſh the fact. For which purpoſe it ſhould firſt be proved, that the ſacred writers believed and taught the exiſtence and agency of this ſtrange and anomalous being; and, ſecondly, that this doctrine was communicated to them by revelation, and that they were authorized to make it known to the world. If neither of theſe points, ſay the antidæmoniſts, can be evinced to the ſatisfaction of an intelligent and critical reader of the Scriptures, the doctrine itſelf is untenable. It is alleged, that the exiſtence of an evil ſpirit is no where expreſsly taught as a doctrine of revelation; that it was unknown to the Jews previouſly to the captivity; and that it was probably borrowed by their learned men, at that time, from the oriental philoſophy, of which it is well known to have conſtituted an eſſential part. After their return it became, in proceſs of time, the popular creed, and the popular language, being gradually faſhioned to it, was adopted equally by thoſe who did, and thoſe who did not believe the theory upon which it was founded. Hence in the New Teſtament we find evil, natural and moral, often aſcribed to the devil, to dæmons, or the ghoſts of wicked men. But neither Jeſus nor his apoſtles, it is ſaid, ever explicitly declare, that they themſelves admitted the philoſophy which governed the language of the country in which they lived, much leſs do they profeſs to teach it as of divine authority. They leave the mythology of evil ſpirits, like many other popular opinions and prejudices, in the ſame ſtate in which they found it, to be corrected in the courſe of time by the principles which they taught, and by the growing good ſenſe of mankind. The firſt teachers of Chriſtianity neither poſitively affirm, nor authoritatively contradict, the exiſtence and agency of an evil ſpirit; but expreſs themſelves upon this ſubject exactly as the reſt of their contemporaries would; and they content themſelves with eſtabliſhing principles, which ſerved gradually to undermine and expoſe the vulgar and popular opinion. It has been ſaid, that the evil ſpirit is entitled to the denomination of the prince of this world (John, xiv. 30.) The true meaning of this expreſſion may probably be, that Jeſus was about to be unjuſtly arreſted by order of the magiſtrate. A ſimilar expreſſion occurs in 1 Cor. ii. 8; where the Jewiſh rulers who crucified our Lord are certainly the perſons intended. As for the paſſage in Jude, v. 6, it ſhould be recollected, that the writer of this obſcure epiſtle is arguing with his readers upon their profeſſed principles, alluding to a mythology which was probably at that time familiar, but is now loſt; nor can any thing be inferred from a compoſition, the genuineneſs of which is known to be very doubtful. But whatever be the true meaning of the paſſage, it proves nothing concerning diabolical agency; for it repreſents the fallen angels not as ranging at liberty, but as bound in chains. Thoſe who reject the notion of diabolical agency, allege the total want of evidence to prove it. As philoſophers, they diſcover no phenomena which countenance the hypotheſis of an inviſible malignant energy; and as attentive readers of the Chriſtian Scriptures, they ſee nothing to warrant ſuch a concluſion, but a ſort of language which a competent acquaintance with the oriental ſtyle would teach them to interpret in a figurative and mythological, and not in a literal and hiſtorical ſenſe. The principle of evil, they ſay, is perſonified, and the properties, operations, and effects of this principle are aſcribed in the eaſtern language and in the ſacred writings to a malignant being. The empire and agency of ſuch a being, in the natural and in the moral world, are ſaid to be incompatible with the rank and powers aſſigned to all creatures, and with the limited ſphere of their operation, and equally inconſiſtent with the rectitude and benevolence of the Supreme Ruler of the univerſe, who would not ſubject his rational offspring, frail and erring in themſelves, to a conflict with powers ſo ſuperior to their own, and the exerciſe of which is ſo adverſe to their ſpiritual and immortal intereſts, as well as to their temporal welfare. It has been further ſaid, that the doctrine of diabolical agency, in the extent to which ſome have maintained it, has an immoral tendency, furniſhes a plea for criminal conduct, and diminiſhes the guilt of the tranſgreſſor; not to add, that it has been the occaſion of a variety of ſuperſtitious opinions and practices of the moſt abſurd and flagitious kind.

The relation we have of the religion of the Americans aſſures us of ſome idolatrous nations, who worſhip the devil: but the term devil muſt not be here taken in the common ſenſe: thoſe people have an idea of two collateral independent beings; one whereof is good, and the other evil. And they place the earth under the guidance and direction of that evil being, which our authors, with ſome impropriety, call the

devil.

devil. The Ethiopians paint the devil white, to be even with the Europeans, who paint him black. Ludolph.

Devil *in a buſh*, in *Botany*. See Nigella.

Devil *in a buſh*, in *Agriculture*, the vulgar name of a weed which is extremely troubleſome in corn lands. Its ſtalks are ſlender, riſing to the height of about a foot, ſometimes branching out at the bottom, having fine cut leaves, ſimilar to thoſe of Dill. The flowers are blue, but the ſeeds are of a blackiſh colour, and rough; from which circumſtance they are highly injurious to wheat, when ground with it. From its being an annual plant, it may be readily extirpated, by being pulled up by the root before it flower.

Devil's *Bit*, in *Botany*. See Scabiosa.

Devil's *Bit*, in *Agriculture*, a name vulgarly applied to a weed which infeſts both corn and paſture, or meadow-lands, (*Leontodon autumnale*). It has a ſtrong, thick, fibrous perennial root, running deep into the ground, and which ſends out ſeveral branching ſtalks, riſing to the height of three feet. It is beſt deſtroyed by having it drawn up by the roots.

Devil's *Bit*, *yellow*, in *Botany*. See Leontodon.

Devil's *Guts*, in *Agriculture*, a name often vulgarly applied to bind-weed; (*Convolvulus arvenſis.*)

Devil's *Iſlands*, in *Geography*, are iſlets, or ſmall ſhoals, the moſt conſiderable of which bears the name of *Joura*, which form the extremity of a chain of iſlands and rocks, placed before the entrance of the gulf of Salonica, and extending to the eaſt, from the great promontory of Volo, the ancient Œantium of Theſſaly, till it faces mount Athos.

Devil's *Iſland*, an iſland of America, on the eaſt ſide of Cheſapeak bay, in Somerſet county, Maryland, between Fiſhing bay and Nanokin river.

Devil, *Iſle of*, one of the ſmaller Molucca iſlands.

Devil's *Mouth*, a name given by ſailors to a frightful volcano, near Leon Nicaragua, in New Spain, ſeated near the lake. N. lat. 13° 10′. W. long. 65° 10′.

Devil's *Noſe*, a promontory on the ſouth ſide of lake Ontario, 16 miles E. of Fiſhing bay, and 23 N. W. of the mouth of Geneſſee river.

Devil, *Sea*, *Diabolus marinus*, in *Ichthyology*, the name of an ugly and ſtrangely ill-ſhaped fiſh. Its noſe or ſnout is bifid, and runs out into two horns; and its ſides are both terminated by thin fins: its ſkin toward the head is variegated with duſky ſpots. It grows to a very conſiderable ſize, being ſometimes caught to ſix or ſeven feet length. Ray's Ichthyology. Append. p. 5. See Lophius.

Devil's *Wall*, in *Geography*, a rock of Hungary, near Gyongyes, in the Matra mountains, forming a façade of thirty feet or more in height, which is conſidered as a natural curioſity. Dr. Robert Townſon, in his travels in Hungary, found it to be nothing more than what is known in Scotland by the name of whin dykes, and attributes its height to the waſhing away of the rocks through which it runs. It is compoſed of a porphyric baſaltes. Many looſe blocks approach nearer to porphyry.

DEVINCTION, Devinctio, in *Antiquity*, was uſed to ſignify a love-charm or incantation to gain the affection of a perſon beloved.

It was done by tying knots, and differed little from what was called obligatio, or catadeſmus. Virgil, in his eighth Eclogue, deſcribes it thus:

" Nectè tribus nodis ternos, Amarylli, colores:
Nectè, Amarylli, modo; & Veneris die, vincula nectо."

DEVISE, Device, or Badge, in *Heraldry*, a name common to all figures, cyphers, characters, rebuſes, mottoes, &c. which by their alluſion to the names of perſons, or families, denote their qualities, nobility, or the like.

Deviſe, in this ſenſe, is of a much older ſtanding than heraldry itſelf; being that which gave the firſt riſe to armories. Thus, the eagle was the deviſe of the Roman empire: S. P. Q. R. was the deviſe of the Romau people, and ſtill continues to be what they call the eſcutcheon of the city of Rome.

The firſt deviſes were mere letters diſtributed on the borders of the liveries, houſings, and banners, and at length on the ſhields. Thus the K was the deviſe of the French kings of the name of Charles, from Charles V. to Charles IX.

There were alſo deviſes by rebuſes, equivocals, or alluſions, both to names and arms. The dukes of Guiſe took for their deviſe an A in an O, to ſignify, *chacun A ſon tour*, every one in his turn: and the houſe of Seneſai, *in virtute & honore ſeneſces*: ſome, that had towers in their arms, *turris mea Deus*, &c.

There are alſo enigmatical deviſes: as that of the Golden Fleece, with *Autre n'aurai*; intimating, that Philip the Good, who inſtituted that order, renounced every other woman but Iſabella of Portugal, whom he then married. Deviſes ſometimes contain entire proverbs: as that of Cæſar Borgia, *aut Cæſar, aut nihil*.

The word deviſe is formed from the Latin *dividere*, and was applied to the things juſt mentioned, as well as thoſe hereafter mentioned; becauſe they ſerve to divide, ſeparate, and diſtinguiſh perſons, parties, &c. Father Menetrier obſerves, that there are as many different kinds of deviſes, as there are different manners of diſtinguiſhing one another, or as there are ſimple figures or words, capable of expreſſing qualities, offices, virtues, actions, &c. of perſons; and of notifying, or diſtinguiſhing them from others.

Badges, impreſſes, and deviſes were greatly in vogue in England from the reign of king Edward I., until that of queen Elizabeth, when they ſunk into diſuſe. Several heraldic writers contend that this event was owing to the diſcontinuance of tilts, tournaments, juſts, and other once faſhionable public and ſolemn proceſſions. They further tell us, that after ſuch diſcontinuance the nobility placed on wreaths and coronets, and bore as creſts, thoſe ſeveral figures which they and their dependants had before worn as badges and deviſes; but in this reſpect they are probably miſtaken, more eſpecially as many of the now exiſting ancient families of the nobility ſtill retain and wear the badges which belonged to their anceſtors.

Devise is now taken, in a more reſtrained ſenſe, for an emblem; or a repreſentation of ſome natural body, with a motto, or ſentence, applied in a figurative ſenſe, to the advantage of ſome perſon.

Father Bouhours gives an accurate explication of the word deviſe, in an extract inſerted in the Memoirs de Trevoux. A deviſe, ſays he, is a compoſition, or aſſemblage of figures drawn from nature and art, called the body; and of a few words adapted to the figure called the ſoul: ſuch a compound, adds he, we make uſe of to denote our thought, or intention, by compariſon: for the eſſence of the deviſe conſiſts in a compariſon: taken from nature, or art, and founded on a metaphor.

This he illuſtrates in the following inſtance: a young nobleman, of great courage and ambition, bore, for his deviſe, in the laſt carouſal at the court of France, a rocket mounted in the air, with this Italian motto, " poco duri," purche m'inalzi;" may I laſt but a ſhort time, provided I mount high: which may be explained thus: as the rocket riſes a great pitch, though it only endures a little while, ſo

it does not concern me to live long, provided I attain to glory and eminence; which is a juſt compariſon.

On this footing, a deviſe, to define it rightly, is a painted metaphor; or rather an enigma inverted: for, whereas enigmas repreſent nature, or art, by the events of hiſtory, and the adventures of fables; a deviſe is a repreſentation of human qualities by natural, or artificial bodies.

Thus to expreſs the character of Louis XIV. a ſun was painted; which yet, luminous as it is, has more power than luſtre: and the better to determine the ſenſe of the painting to this ſignification, the Caſtilian motto is added; "Mas virtud que luz." The perſonal merit of Mary, queen of Scots, was repreſented by a pomegranate, with theſe words: "Mon prix n'eſt pas de ma couronne:" and the talent of an apoſtolical perſon, who became all things to all men, by a looking-glaſs, with thoſe words of Saint Paul, "Omnibus omnia."

Deviſes are uſed on coins, counters, ſeals, ſhields, triumphal arches, artificial fire-works, and other ſolemnities. They are a ſort of images, very pertinently and artfully repreſenting the enterpriſes and intrigues of war, love, piety, ſtudy, fortune, &c.

The French have diſtinguiſhed themſelves in this way, eſpecially ſince the time of cardinal Mazarin, who had a wonderful fancy for deviſes.

The Italians have reduced the making of deviſes into an art, and laid down laws and rules for this purpoſe. Some of the principal are, 1. That there be nothing monſtrous, or extravagant, in the figures; and nothing contrary to the nature of things, or to the common opinion of mankind. 2. That figures be not joined which have no affinity, or relation, to each other; the metaphor being to be founded on ſomething real, and not on hazard, or imagination, excepting ſome whimſical combinations eſtabliſhed in mythology, which cuſtom, and the authority of the poets, have made paſs for natural. 3. That the human body be never taken into deviſes; as this would be to compare a man with himſelf. 4. That there be a ſort of unity in the figures which compoſe the body: we do not mean, that there muſt only be a ſimple figure; but that, if there be ſeveral, they muſt have a relation, and ſubordination to each other, ſo that there be one principal figure whereon all the reſt depend: though ſtill the fewer figures there are in the body of the deviſe, and the leſs they are confuſed, the more perfect and elegant is the deviſe. 5. The motto, which is to animate the figure, muſt agree ſo accurately thereto, as that it could not ſerve for any other. 6. Nothing is to be named that appears to the eye, and which the bare inſpection might notify. 7. The motto is to have a complete ſenſe of itſelf; for, being to make a compound with the figure, it muſt only be a part, and, conſequently, muſt not ſignify the whole. If the words alone have a complete ſignification, you have a full and diſtinct notion independently of the figure; whereas the ſignification ſhould reſult from both. 8. The ſhorter the motto, the more beautiful: and a ſuſpenſion of the ſenſe, which leaves ſomewhat to gueſs, is one of the principal graces of the deviſe. Laſtly, it is accounted a happineſs, where the words of a poet are applied in a ſenſe which he never dreamed of, and yet ſo pertinently, that it ſhould ſeem they had been intended for the ſame.

Devise, or *Diviſe*, in *Common Law*, the act whereby a teſtator gives, or bequeaths, his lands, or goods, by his laſt will, in writing. Though, in ſtrictneſs, a deviſe of goods is more properly termed a bequeſt.

He who makes the deviſe is called the deviſor; and he to whom it is made, the deviſee.

A deviſe in writing is, in conſtruction of law, no deed; but an inſtrument by which lands are conveyed.

The words of a will the law interprets in a larger, and more favourable ſenſe, than thoſe of a deed: for if land be deviſed to a man to have to him for ever, or to have to him and his aſſigns; in thoſe caſes, the deviſee ſhall have a fee ſimple: yet if given in the ſame manner by feoffment, he ſhall have but an eſtate for life.

So, if one deviſe land to an infant in his mother's belly, it is a good and valid deviſe; though it is otherwiſe by feoffment, grant, or gift. For, in thoſe caſes, there ought to be one of ability to receive preſently; otherwiſe it is void. See Deed, and Will.

Devise, *Executory*. See Executory *Deviſe*.

DEVIZES, in *Geography*, a market and borough town of Wiltſhire, England, is a place of remote antiquity; and though it has not been proved to be a Roman ſtation, yet various ancient remains, belonging to the Romans, have been found here. Dr. Stukeley contends, that a town, a ſtation, called *Punetuobiee*, occupied the ſite of the preſent Devizes, and that it was ſurrounded by a "vallum and ditch." Dr. Davies, in a work containing much ingenious criticiſm, entitled "Origines Diviſianæ," controverts the opinion of Stukeley. A ſtrong caſtle, on a commanding ſituation, was built here at an early period. This was occupied by Roger biſhop of Sarum, during the reign of Henry I.; and here, in the ſucceeding reign, the biſhop, with his ſon, and nephews, were made priſoners within its gates. In the various civil wars that progreſſively occurred in England, this caſtle was the ſcene of repeated conflicts, and its walls frequently aſſaulted. In the 27th year of Edward I, that monarch ſettled this caſtle and town, with ſeveral other places in Wiltſhire, on his queen Margaret, by way of dower. Leland deſcribes this fortreſs in the following terms. "It ſtood on the ſouth-weſt ſide of the town, ſtately advanced on a high ground, defended partly by nature, partly by dykes. It was made by biſhop Roger; and ſuch a piece of caſtle work, ſo coſtly and ſtrongly, was never afore, or ſince, ſet up by any biſhop of England. The keep, or dungeon, on a hill caſt up by hand, is a piece of work of incredible coſt; there appeared on the gate ſix or ſeven places for portculliſes, and much goodly building was in it. It was then ruined; part of the front of the towers of the gate of the keep and chapel was carried full profitably to build Mr. Baynton's place at Bromham, ſcarce three miles off; and divers goodly towers in the outer hall were going to ruin; the principal leading into the town was yet of great ſtrength." The fortreſs thus deſcribed, has ſince been entirely deſtroyed; and nothing remains but parts of the valla and mount. Theſe are now encloſed within the pales of a gentleman's ſhrubbery.

During the civil wars of the ſeventeenth century, Devizes was occupied by a party of the king's army, which was attacked by the parliamentary forces under ſir William Waller. A dreadful battle enſued, and terminated in favour of the royaliſts. About ſix hundred of the parliamentary ſoldiers were ſlain, and nine hundred more taken priſoners.

As a borough, Devizes has had ſeveral charters granted it by different monarchs. The firſt of theſe was conferred by the empreſs Maud, and confirmed by her ſon, Henry I. Succeeding kings either ratified, or extended the liberties and immunities of the burgeſſes.

The town occupies an elevated ſite, and is therefore deprived of any river; which is of ſo much importance and utility to places of trade, and indeed to every ſpot where perſons

perſons make a permanent ſettlement. Devizes conſiſts of two pariſhes, and a chapelry: and is provided with two churches and one chapel, belonging to the eſtabliſhed religion. Beſides theſe there are four meeting-houſes.

Richard of Devizes, and Joſeph Allen, were natives of this town.

About two miles north-eaſt of Devizes is Roundway-hill, on the ſummit of which is a large entrenchment, which comprehends an area of about 140 yards, by 120 yards. North-eaſt of this is another large earth-work fortreſs, called Oldbury caſtle. Between theſe are a very conſiderable vallum and ditch, which extend ſeveral miles from weſt to the eaſt, and is known by the name of Wanſdyke. In the vicinity of Devizes is New park, a handſome ſeat, belonging to Mrs. Sutton: and Stoke park, the ſeat of Joſhua Smith, eſq. M.P. The latter houſe is a commodious and handſome building, and the park abounds with fine woods, and is ornamented with a large lake.

Devizes contains 890 houſes, and 4851 inhabitants. It has two weekly markets, and ſix fairs annually.

DEULE, a ſmall river of the department of the North in France, which forms the canal of Douay at Lille, and runs into the Lys.

DEULEMONT, a town in France, in the department of the north, at the conflux of the Deule and the Lys; ſix miles N. W. of Lille.

DEUNA. See DEVA.

DEUNX, a diviſion of the Roman libra, or pound, containing eleven ounces; or eleven twelfths of any thing. See As.

DEVOIRS OF CALAIS, in our *Old Statutes*, cuſtoms due to the king for merchandize brought to, or carried out of Calais, when our ſtaple was there. 34 Edw. III. c. 18. and 2 Rich. II. ſtat. 1. c. 3.

Devoir is French, ſignifying *duty*.

DEVOLVED, ſomething acquired by right of devolution. Such a right is devolved to the crown: ſuch an eſtate devolved on M—— by the death of N——.

The word is alſo uſed for a right, acquired by a ſuperior, of conferring a benefice, when the inferior, and ordinary collator, has neglected to confer, or has conferred it on an unqualified perſon.

If a patron neglects to preſent a benefice in ſix months, the preſentation lapſes, or devolves, upon the biſhop, from thence to the primate, and from thence to the king.

DEVOLUTION, in the *French Law*, a right acquired by deſcent, or ſucceſſion, from degree to degree.

Devolution, in general, is an impediment provided by the cuſtoms of ſeveral provinces, whereby the huſband who ſurvives his wife, or the wife ſurviving her huſband, is prohibited to alienate the real and immoveable effects of the deceaſed, and obliged to preſerve them for the children iſſued from that marriage; ſo that they may ſucceed thereto in excluſion of thoſe born of a ſecond marriage.

DEVON, in *Geography*, a river of Scotland, in Clackmannſhire; which is navigable for barges to the coal mines near Madlock fort, about 2½ miles from its influx into the Forth river.

DEVONA, in *Ancient Geography*, a town of Germany, according to Ptolemy.

DEVONSHIRE, in *Geography*, a county of England, bounded on the north by the Briſtol channel, on the ſouth by the Engliſh channel, on the eaſt by Somerſetſhire and Dorſetſhire, and on the weſt by Cornwall. This area of country meaſures about 73 miles in length, and 63 in breadth; and is eſtimated to contain nearly 1,600,000 acres of land. The external aſpect of the county is exceedingly varied and irregular; and the heights in many parts, but particularly in Dartmoor and its vicinity, ſwell into mountains: the altitudes of the principal eminences being from 1500 to 1800 feet. On approaching this tract from the ſouth and ſouth-eaſt, the eye is bewildered by an extenſive waſte, exhibiting gigantic tors, large ſurfaces covered with vaſt maſſes of ſcattered granite, and immenſe rocks, which ſeem to have been precipitated from the ſteep declivities into the vallies. A prominent natural feature of this county is Dartmoor, or Dartmoor Foreſt, which has been already deſcribed in a former volume of this work.

The vale of Exeter differs widely in appearance from Dartmoor; though in ſome parts, particularly between Tiverton and Exeter, and the latter place and Collumpton, it has an irregular billowy ſurface, and preſents eminences of conſiderable magnitude; but the central and ſouthern parts preſerve the vale character. The area of this diſtrict contains about 200 ſquare miles: its boundaries on the north, are the hills that range from Clanaborough, by Halberton and Uffculm, to Blackdown, a dreary mountainous ridge, which, with its contiguous branches, ſkirt the eaſtern ſide of the vale: on the ſouth-eaſt it is bounded by the heights of Sidmouth-hill, Eaſt-down, and Woodbury; and on the weſt by the mountainous tract of Haldon, and the undulating eminences that ſtretch toward Bow. The diſtrict called the South-hams, is frequently termed the garden of Devonſhire, from its fertility. Its natural boundaries are Dartmoor, and the heights of Chudleigh, on the north; Plymouth Sound on the weſt; Torbay on the eaſt; and on its ſouthern point, the Engliſh channel. Its area, including the rich valley of the Dart, which extends towards Aſhburton, comprehends nearly 250 ſquare miles. This tract is ſtrikingly diverſified by bold ſwells, winding coombs, and fine vales; and in many parts, particularly towards the north, the ſcenery is pictureſque, and highly romantic. Numerous ſprings flow from the ſides of the hills, and uniting into brooks and rivulets, ſpread luxuriance and beauty through a conſiderable extent of country. Great quantities of cyder are made in this diſtrict, as well as in the vale of Exeter; and as almoſt every farm has its orchard, the general produce affords a conſiderable ſurplus for exportation. Preference is generally given to thoſe apples which are moſt juicy, yet they are ſeldom ſorted: the red-ſtreak is the ſpecies conſidered as moſt productive. The ſweet cyder is chiefly made in the vicinity of Staverton, but of the ſame kind of fruit as the rough: the ſweet taſte ariſes from its being often racked, which checks the fermentation. The cyder made in the neighbourhood of Exeter, Chudleigh, Newton-Buſhel, Peignton, Totneſs, and ſome contiguous places, is deemed of ſuperior flavour. In this diſtrict alſo a conſiderable quantity of butter is made: the mode of producing the cream is almoſt peculiar to Devonſhire; it is raiſed by heating the milk in earthen or braſs pans, and is then worked into butter by the hand of the dairy-maid, who turns it all one way in a bowl or tub, without the aſſiſtance of the churn. After the cream is taken off, the ſcalded milk is made into an inferior kind of cheeſe.

The breed of catttle in Devonſhire is ſpoken of by Mr. Marſhall, in his Rural Economy of the Weſt of England, as being in many reſpects the moſt perfect in England. This accurate obſerver imagines all the varieties to be ſprung from the native breed of the iſland, and remarks, that with the exception of colour, they exactly reſemble the wild cattle which are ſtill preſerved at Chillingham park, in Northumberland. The Devonſhire breed are of the middle-horned kind, but vary conſiderably, both in ſize and form, in different parts of the county. "North Devon," ſays

Mr. M., " takes the lead in both theſe particulars; and its breed are in both nearly what cattle ought to be. In ſize, they are rather below the deſirable point for the heavier works of huſbandry; but they make up for this deficiency, in exertion and agility; and are, beyond compariſon, the beſt workers I have any where ſeen. As dairy cattle the Devonſhire breed are not excellent; rearing for the eaſt-country graziers having long been the main object of the farmers of this county; but as grazing cattle, individuals in every part of the county ſhew the breed to be excellent. In Weſt Devonſhire the breed is conſiderably ſmaller than in the northern diſtrict, and their quality in every reſpect lower." Oxen have, from time immemorial, been the plough-team of this county; ſometimes with horſes before them, but more generally alone. Four aged oxen, or ſix growing ſteers, are the uſual number yoked to one plough.

Among the products of Devonſhire ſhould be noticed the great variety of fiſh which abound in its rivers and on its coaſts; and, in addition to the home conſumption, afford a very conſiderable ſupply to the Bath and London markets. In the rivers Tamar and Tavy, great numbers of ſalmon are annually taken, producing large ſums to the proprietors of the eſtates which have the right of fiſhing. The ſalmon-fiſhery on the Tavy is appendant to the lands of Buckland-place, the ſeat of the Drake family, by whoſe anceſtor, the celebrated circumnavigator, the eſtate was purchaſed. The weir belonging to this fiſhery is a work of conſiderable magnitude. It conſiſts of a ſtrong dam, about twelve feet high, thrown acroſs the river in a part where two projecting rocks ſerve as buttreſſes to the maſonry, which is built arch-wiſe to reſiſt the preſſure and force of the waters in times of flood, when they collect from the ſlopes of the Dartmoor hills, and ruſh down with extraordinary impetuoſity. The fiſhing ſeaſon commences in the Tavy about the middle or latter end of February, (but on the Tamar not till ſeveral weeks later,) and cloſes in October or November, when the weir is thrown open. When the water is clear, many ſalmon are taken with the ſpear by poachers, who throw this weapon with great dexterity. The ſalmon of the Tamar and Tavy are of inferior quality to thoſe taken in many other rivers in Devonſhire. Thoſe of the Exe are conſidered the moſt delicate, and fineſt flavoured. In the river Dart they are caught in great abundance; their uſual weight is from ſix to fourteen pounds each: though they are frequently taken of the weight of twenty pounds or upwards. Thoſe that aſcend the Teign are often ſold at Chudleigh ſo low as two-pence or three-halfpence *per* pound. The prevailing river fiſh of Devon is the trout, which are provincially called ſhots, from their rapid motion through the water. The river Otter is remarkable for its trout, and ſalmon-peal; the former having a peculiarly rich flavour, and the latter being very large and firm. The plaiſe of the Devonſhire rivers are eſteemed particularly delicious; more ſo, perhaps, than thoſe of any other part of the world. The torpedo, or electric ray, has occaſionally been caught at Torbay, and ſometimes in the river Dart.

The mineralogical ſubſtances of Devonſhire are various and numerous; and from the confuſed intermixture of the ſtrata in different parts of the county, it is conſidered that earthquakes or volcanoes have prevailed here at ſome remote periods.

Among the minerals of the calcareous genus, limeſtone is the moſt conſiderable, being found of almoſt every deſcription in different parts of the county: many quarries have been opened, to procure it for the purpoſes of agriculture, building, and ornament. In the eaſtern part of Devon it approaches to the nature of chalk, and, in general, is ſcarcely ſuſceptible of a poliſh: in other parts, and particularly in the South-hams, it aſſumes the qualities of marble, and for hardneſs and beautiful veinings, reſembles the beſt marbles of Italy; and when poliſhed, is hardly inferior in luſtre. In the pariſh of South Moulton are many quarries of black marble, variegated with ſmall ſtreaks of white, which takes a fine poliſh, but is moſtly burnt into lime. Gypſum is obtained in various parts of the county, though not in particular abundance: near Plymouth it appears in union with the lime-ſtone. It is alſo found at Salcombe-Regis, and at many places in the lime-ſtone diſtrict, ſouth-weſt of Exeter. In the mines of Beer-Ferris fluor-ſpar is procured in great plenty, and of ſeveral varieties, both as to ſhape and colour: a ſpecimen of ſtellated ſpar has been found at Oxton, near Haldon.

Argillaceous ſubſtances abound in almoſt every part of the county. In the vale of King's-Teignton, pipe and potter's clay is procured in great quantities; and ten or twelve thouſand tons are annually ſent from the port of Teignmouth, to ſupply the potteries of London, Liverpool, and other parts. Schiſtus is common to almoſt the whole county, and conſiſts of a great number of laminæ, differing in thickneſs, from three feet to half an inch.

In the ſilicious claſs are quartz cryſtals, which have been found in various parts of Devonſhire, but generally very ſmall. On Dartmooor they have been ſometimes met with in the fiſſures of the granite: they have alſo been diſcovered in abundance in the red ſoil, or rock, at Rougemont caſtle; and near Samford-Spinney, in great plenty: their common form is the hexagonal priſm, terminating with two pyramids. Flints exiſt in great abundance, but particularly in the mountainous tract of Haldon. The principal kinds of free-ſtone are dug in the pariſhes of Salcombe, Branſcombe, and Beer.

Varieties of lava, here called iron-ſtone, whin-ſtone, and baſalt, are found in different parts of the county, and bear a ſtriking reſemblance to the Derbyſhire toad-ſtone: it exiſts, however, in the greateſt plenty in the vicinity of Exeter; and the entire rock on which the caſtle ſtands has been conſidered as volcanic.

Granite, called alſo moor-ſtone, is, as in Cornwall, found in various places, but particularly in Dartmoor, where the mountains commence which extend into that county. It generally lies in vaſt irregular maſſes, and in great variety, as to texture and colour. Specimens of the red granite are exceedingly beautiful when well poliſhed. On expoſure to the atmoſphere, it acquires ſolidity; but when firſt raiſed, may be worked with little difficulty.

The moſt remarkable of the inflammable ſubſtances diſcovered in Devonſhire is the Bovey coal, the origin of which has given riſe to conſiderable diſcuſſion among geologiſts. It is obtained in the extenſive flat called Bovey Heathfield, which appears to have been formerly covered by the tide, and is ſuppoſed to be lower than the level of the ſea. The nature and peculiar properties of this mineral, are fully deſcribed by Mr. Polwhele, in his Hiſtory of Devonſhire.

Pyrites is found in various parts of the county, and frequently appears in globular balls of different ſizes. A great number were met with a few years ago in the ſchiſtus, near Chudleigh, lying at ſome diſtance from each other. Several of them are in the cabinet of P. Raſhleigh, eſq. of Menabilly.

The principal metallic ſubſtances of Devonſhire are the ores of tin, lead, iron, and manganeſe. Gold, ſilver, copper, biſmuth, antimony, and cobalt have alſo been found, but in ſmall quantities. The tin-works were anciently numerous and valuable, but have in a great meaſure been

abandoned; the mines of Cornwall being conſiderably more productive: though in the reign of king John, Devonſhire produced greater quantities of tin than that county; its coinage being ſet to farm at 100*l.* annually, and that of Cornwall at no more than 100 marks. The importance of its trade in tin is, indeed, manifeſted from its ſtannary courts, and coinage towns, of which there are four; Plympton, Taviſtock, Aſhburton, and Chagford. The members of theſe courts have the privilege from time to time, and under the direction of the lord warden, of chooſing certain jurats to meet in a general aſſembly at Crockern Tor, in the midſt of Dartmoor, with power to make laws for the regulation of the mines and ſtannaries. "There are numberleſs ſtream-works on Dartmoor, and in its vicinities," Mr. Polwhele obſerves, "which have lain forſaken for ages. In the pariſhes of Manaton, King's-Teignton, and Teigngrace, are many old tin-works of this kind, which the inhabitants attribute to that period when wolves and winged ſerpents were no ſtrangers to the hills or the vallies. The Bovey Heath-field has been worked in the ſame manner; and, indeed, all the vallies from the Heath-field to Dartmoor bear the traces of ſhoding and ſtreaming; which, I doubt not, was either Britiſh or Phenician. Lead was alſo familiar to the weſtern Britons. That the Danmonians had iron-works is plain from Cæſar, who mentions the *exigua copia* of our iron in the maritime parts: the iron-pits of Blackdown were, I conceive, originally Britiſh, and were afterwards worked by the Romans." The lead ore of this county is chiefly of a greyiſh blue colour, but of ſeveral varieties. The potter's or teſſellated ore is of a ſhining, rectangular, tabulated ſtructure, always breaking into cubical granules: another kind is of a flaky, ſmooth, gloſſy texture, breaking into more ponderous fragments: and a third ſort is very cloſe grained; fracture, ſparkling and uneven, and very rich in ſilver: the latter variety has been obtained in plenty at the Beer-ferris mines. Some very rich lead ore was diſcovered a few years ago near the ſurface at Comb-martin. Iron-ſtone is found in various parts of the county, and in many varieties; but does not appear to be particularly rich in metal. Native ſilver has been found in different ſubſtances, and in various forms; granular, filamentous, capillary, arboreſcent, and cryſtallized. Manganeſe is chiefly obtained at Upton Pyne, where it was diſcovered about forty years ago. Antimony has been found in ſeveral places within the three pariſhes of Chudleigh, Hennock, and South Bovey. Cobalt, interſperſed with numerous filaments of ſilver, has been diſcovered in conſiderable abundance at Sampford.

Mineral waters are very numerous in this county, and are chiefly of the chalybeate kind; though they have not in any particular degree been appropriated to medicinal purpoſes. The ſtrongeſt ſprings of this deſcription ariſe at Gubb's Wall, near Cleave; at Bella Marſh, near King's-Teignton; at Ilſington, in the vicinity of Totneſs; at Brook, near Taviſtock; and at Bampton: the ſpring at the latter place is ſaid to be more ſtrongly impregnated with iron than any other.

Devonſhire abounds with rivers: ſome of them flow northward into the Briſtol Channel; and others ſouthward into the Britiſh Channel: being enlarged in their progreſs by innumerable leſſer ſtreams. The principal are the Taw, the Torridge, the Dart, the Teign, and the Exe: the moſt conſiderable of the ſecondary rivers are the Tavy, the Plym, the Yealm, the Arme or Erme, the Aven, the Otter, the Sid, the Axe, and the Lyn. The Tamar is ſometimes included among the Devonſhire rivers, as being equally common to this county as to Cornwall, but is more generally conſidered as belonging to the latter from riſing within its limits.

The ancient inhabitants of Devonſhire were the Danmonii. Under the Roman ſubjugation, this county was included in the diſtrict called Britannia Prima: by the Saxons it was made part of the kingdom of Weſſex; and ſo continued till the incorporation of the Saxon ſtates into one monarchy under Egbert.

Devonſhire is in the dioceſe of Exeter, and in the weſtern circuit. It is divided into thirty-three hundreds; and contains 40 market towns, 394 pariſhes, 61,190 houſes, and 343,000 inhabitants. The members returned to parliament are twenty-ſix: two for the county, and two for each of the following places; Exeter, Totneſs, Plymouth, Oakhampton, Barnſtaple, Plympton, Honiton, Taviſtock, Aſhburton, Dartmouth, Bere-Alſton and Tiverton. The county pays twenty-one parts of the land-tax; and ſupplies 1600 men to the militia. The aſſizes are held at Exeter. Marſhall's Rural Economy of the Weſt of England. Polwhele's Hiſtory of Devonſhire. Beauties of England and Wales.

DEVONSHIRING, in *Agriculture*, a name formerly applied to the proceſs of paring and burning.

DEVOTION, of *devoto*, from *devoveo*, I conſecrate, a ſincere, ardent worſhip of God.

Monſ. Jurieu defines devotion, a ſoftening and yielding heart, with an inward conſolation, which the ſouls of believers feel in the exerciſes of piety.

Devotion, according to Dr. Blair (ſee Sermon x. vol. i.) is the lively exerciſe of thoſe affections, which we owe to the Supreme Being, comprehending ſeveral emotions of the heart, which all terminate on the ſame great object. The chief of theſe are veneration, gratitude, deſire, and reſignation. Veneration is an affection compounded of awe and love, and looks up to the Diety, as he is in himſelf:—gratitude for the divine benefits is a warmer emotion than ſimple veneration, and regards God as he is towards us:—deſire regards the favour of the Supreme Being as its chief good and final reſt:—and theſe ſeveral ſentiments and affections produce, and are accompanied by, an entire reſignation of the ſoul to God, as the conſummation of truſt and hope. Accordingly, devotion expreſſes, not ſo much the performance of any particular duty, as the ſpirit which ought to animate all religious duties. It ſtands oppoſed, not merely to downright vice; but to a heart which is cold, and inſenſible to ſacred things; which from compulſion, perhaps, and a ſenſe of intereſt, preſerves ſome regard to the divine commands, but obeys them without ardour, love, or joy. This excellent preacher obſerves, that in the culture and exerciſe of a devout ſpirit, it is of the utmoſt conſequence to guard againſt extremes of every kind in religion; as ſuperſtition, on the one hand, which attaches men, with immoderate zeal, to the ritual and external part of religion, and enthuſiaſm, on the other, directing their whole attention to internal emotions, and myſtical communications with the ſpiritual world: while, neither the one, nor the other, has paid ſufficient regard to the great moral duties of the Chriſtian life. Some perſons, eagerly anxious to avoid theſe two great abuſes of religion, have neglected to obſerve, that there are extremes oppoſite to each of the former, into which they are in danger of precipitating themſelves. Thus, the horror of ſuperſtition has ſometimes produced contempt for all external inſtitutions; as if it were poſſible for religion to ſubſiſt in the world, without forms of worſhip, or public acknowledgement of God. Others, well affected in the main to the cauſe of goodneſs, obſerving that perſons of a devout turn have at times been carried away, by warm affections, into unjuſtifiable exceſſes,

have thence haſtily concluded, that all devotion was akin to enthuſiaſm; and ſeparating religion totally from the heart and affections, have reduced it to a frigid obſervance of what they call the rules of virtue. In order to guard againſt this extreme, it ſhould be conſidered, that true devotion is rational and well-founded; that it is of the higheſt importance to every other part of religion and virtue; and alſo, that it is moſt conducive to our happineſs. Pure and rational devotion, as our author well obſerves, ſhould be carefully diſtinguiſhed from that which is, in any degree, ſpurious and adulterated. For this purpoſe devotion ſhould not be made to conſiſt in the mere performance of any external act of worſhip; nor ſhould the pleaſures and advantages of it be conceived as open indiſcriminately to all; nor ſhould it be repreſented as requiring an entire retreat from the world, or as enjoining a total contempt of all the pleaſures and enjoyments of human ſociety; nor again, ſhould it be believed, that devotion nouriſhes a ſpirit of ſeverity, in judging of the manners and characters of others; or, that perpetual rapture and ſpiritual joy belong to devotion.

Uuder the name of devotions are uſually underſtood certain religious practices, which a perſon makes it a rule to diſcharge regularly; and with reaſon, if this exactitude be founded on ſolid piety; otherwiſe it is vanity, or ſuperſtition.

Devotion, among the Romans, was a ſort of ſacrifice, or ceremony, whereby they conſecrated themſelves to the ſervice of ſome perſon.

The ancients had a notion, that the life of one might be redeemed by the death of another: and hence were thoſe devotions ſo frequent for the lives of the emperors. Theſe were either private or public; of the former ſort were the devotions of the two Decii and of Curtius, who devoted themſelves to ſave the Romans. The devotion of Decius, who, after devoting himſelf to his country, threw himſelf into the hands of his enemies, and was killed, is ſaid to have gained the Romans the victory. On this occaſion Decius gave notice to the pontiff Valerius, to pronounce the form of devoting: "Deorum ope," ſays he, "Valeri, opus eſt; agedum; præi verba quibus me pro legibus devoveam." The public devotions were performed by the dictator or conſul, at the head of an army. The form is tranſmitted to us by Macrobius (Sat. l. 3. 9.) and is as follows: "Father Dis, Pluto, Jupiter, Manes, or by whatever name it is lawful to call you, I beſeech you to fill this city of Carthage, and the army I mean, with terror and conſternation: Grant that they who bear arms againſt our legions and army, may be put to the rout, that the inhabitants of their cities, and of their fields, with all that dwell in them, of every age, may be devoted to you, according to the laws, by which our greateſt enemies are devoted. I, by the authority of my commiſſion, devote them, in name of the Roman people, in name of the army, and in name of our legions, that you may preſerve both the commanders and thoſe who ſerve under them."

But devotion to any particular perſon was not known till Auguſtus. The day after the title Auguſtus had been given to Octavius, Pacuvius, a tribune of the people, began to ſay, he would devote and conſecrate himſelf to him, as was practiſed among the barbarous nations, to obey him even at the expence of life, if he were commanded. His example was immediately followed by all the reſt; and it came at length to be eſtabliſhed into a cuſtom, never to go to ſalute the emperor, without declaring, they were devoted to him. Auguſtus, though ſeeming to oppoſe this vile and infamous flattery, yet rewarded the author.

Cornelius Nepos uſes the word devotion for a kind of puniſhment, conſiſting of direful curſes, and marks of infamy. See Accursed, and Execration.

Whenever the law devoted any one to death, it was permitted to kill him. One of Romulus's laws was conceived in theſe terms: "Si patronus clienti fraudem faxit, ſacer eſto. *i. e.* If any patron defrauds his client, let him be devoted." It was to Pluto or Dis, and the other infernal deities, that criminals were devoted.

DEVOURING, in *Heraldry*. When fiſhes are borne in an eſcutcheon, in a feeding poſture, the heralds denominate it devouring; becauſe fiſhes ſwallow all their food whole.

DEUPRAG, in *Geography*, a town in the country of Thibet; 15 miles S. of Sirinagur.

DEVRACOTA, a tract of land on the coaſt of Orixa, in the ſouthern part of Hindooſtan, called the Deccan, which had been ceded to the French Eaſt India company by the viceroys of Golconda. It is about 20 miles S. of Maſulipatam, and renowned for its uncommon fertility. Its clear value to the French, before 1754, was 100,000 rupees, or 240,000 French livres *per annum*. Herbin Statiſtique de la France, vol. vii.

DEUREN, or Duren, anciently *Marcodurum*, was formerly a town of the duchy of Juliers, in the circle of Weſtphalia, in Germany, but is now a town of France, in the department of the Roer, diſtrict of Aix-la-Chapelle, ſituated on the river Roer, 15 miles S. of Juliers, 30 S. W. of Cologne. E. long. 9°. Lat. 50° 46'. It contains 3489 inhabitants, and is the chief place of a canton, which, in 57 communes, compriſes a population of 16,695 individuals.

DEURIOPUS, in *Ancient Geography*, a country of Macedonia, forming a part of Pæonia; ſituated between the rivers Axius and Erigon. Its principal towns were Bryanium, Alalcomenæ, and Stymbara, ſuppoſed to be the ſame with Stubera.

DEUS Dedit, or God's gift, in *Biography*, pope, ſucceſſor to Boniface IV. in the year 614. He reigned but three years; and we have but few particulars tranſmitted to us reſpecting him, farther than that he was a native of Rome, and ſon of a ſubdeacon of the church, and that his election to the pontificate was unanimous. He was a pious and benevolent man, and to him have been imputed divers miracles. Moreri mentions one in which he healed a leprous man by bringing their mouths in contact. The biographer probably gave little credit to ſuch a report, but thought it neceſſary to inſert it to quiet the minds of the devotees to the Catholic religion. Moreri.

DEUS Vult, *Deus le Volt*: the cry of battle among the Croiſaders, in their ſeveral expeditions into the Eaſt for the recovery of the Holy Land. In the council of Clermont, held by pope Urban II, in the year 1096, for inſtituting the firſt croiſade, the whole aſſembly there preſent, laity, as well as clergy, anſwering his exhortations with a general and ſudden cry of *Deus Vult*, It is the will of God, the pontiff repreſented this as the effect of inſpiration, and appointed thoſe words to be the ſignal for attacking and rallying in the enſuing battles againſt the Saracens, which they continued to be in all future croiſades as well as in the firſt. See Croisade.

DEUSINGIUS, Anthony, in *Biography*, a learned phyſician, and voluminous writer on every part of medicine, and on other branches of natural philoſophy, was born at Meurs, in the duchy of Juliers, October 16th, 1612. After acquiring a proficiency in the learned languages, to which were added the Arabic and Perſian, he went to Leyden,

den, where he completed his education by taking the degree of doctor in medicine, in 1634. Three years after he was appointed profeſſor in mathematics at Meurs. In 1639, he was called to ſucceed Iſaac Pontanus, in the chair of natural philoſophy and mathematics, and, in 1642, to that of medicine at Harderwick, to which was added the office of phyſician to the city. From Harderwick, he went to Groningen, where, in addition to the offices ſimilar to thoſe he held at Harderwick, he was appointed rector of the univerſity, and ancient of the church. Amid the buſineſs which ſuch accumulated duties heaped upon him, he found leiſure to write a greater number of treatiſes on the different parts of medicine and philoſophy, than have fallen from the pen of almoſt any other man. In the liſt Haller has given, we find the titles of fifty-four treatiſes, or diſſertations. But a ſmall number of theſe are on practical ſubjects. Many of them are metaphyſical, and a ſtill greater number are controverſial. Theſe are written with great acrimony, particularly thoſe relating to his controverſy with Silvius, though the ſubjects, which are moſtly phyſiological, do not ſeem calculated to excite ſo much rancour as we ſee infuſed into them. A few of the titles follow, for the reſt the reader is referred to the different parts of the Bibliotheca of Haller. "Joannes Cloppenburgius, Weautontimorumenos, ſeu retorſio injuriarum de libello falſidico, cui titulus, Res judicata, cumulatarum," 1643, 4to. The ſubject of diſpute is the nature of the ſoul, and on the intelligences that direct the courſe of the ſtars. "Canticum Avicennæ de Medicina, ex Arab. Lat. reddit," 1649, 4to. "Diſſertationes duæ, prior de motu Cordis et Sanguinis, altera de lacte ac nutrimento fœtus in utero," 4to. 1651. In this he defends the circulation of the blood, as deſcribed by our countryman Harvey. "Synopſis Medicinæ univerſalis," 1649., &c. Deuſingius died in the winter of 1666, of a pleuritic affection, occaſioned by taking a long journey, in very ſevere weather, to viſit the count of Naſſau, to whom he was phyſician. Eloy Dict. Hiſt.

DEUTEROCANONICAL, compounded of *δευτερος*, *ſecond*, and *κανονικος*, *canonical*, in *Biblical Hiſtory*, an appellation given to certain books of the Holy Scriptures, which were added to the canon after the reſt; either becauſe they were not wrote till after the compilation of the canon, or becauſe of ſome diſputes as to their canonical authority.

The Jews, it is certain, acknowledge ſeveral books in their canon, which were put there later than the reſt. They ſay, that, under Ezra, a great aſſembly of their doctors, which they call, by way of eminence, the *great ſynagogue*, made the collection of the ſacred books, which we have now in the Hebrew Old Teſtament: and they agree, that they put books therein which had not been ſo before the Babyloniſh captivity. Such are thoſe of Daniel, Ezekiel, Haggai, &c. and thoſe of Ezra and Nehemiah.

And the Romiſh church has ſince added others to the canon that were not, nor could be, in the canon of the Jews; becauſe ſome of them were not compoſed till after the canon was formed. Such is the book of Eccleſiaſticus; with ſeveral of the apocryphal books, as that of the Maccabees, Wiſdom, &c. Others were added ſtill later, becauſe their canonical authority had not been yet examined; and, till ſuch examen, and judgment, they might be ſet aſide, at pleaſure.

But ſince that church has pronounced as to the canonical authority of theſe books, there is no more room now for her members to doubt of them than there was for the Jews to doubt of thoſe of the canon of Ezra: and the deuterocanonical books are, with them, as canonical as the protocanonical; the only difference between them conſiſting in this, that the canonical authority of the one was not generally known, examined, and ſettled, ſo ſoon as that of the others.

The deuterocanonical books, in the modern canon, are, the book of Eſther, either the whole, or at leaſt the ſeven laſt chapters of it; the Epiſtle to the Hebrews; that of James; and that of Jude; the ſecond of St. Peter; the ſecond and third of St. John; and the Revelation. The deuterocanonical parts of books are, the Hymn of the Three Children; the Prayer of Azariah; the hiſtories of Suſanna, of Bel and the Dragon; the laſt chapter of St. Mark; the bloody ſweat, and the appearance of the angel, related in St. Luke, chap. xxii. and the hiſtory of the adulterous woman in St. John, chap. viii. See CANON and BIBLE.

DEUTERONOMY, one of the ſacred books of the Old Teſtament; being the fifth book of the law, and the laſt of thoſe written by Moſes; cloſing, according to the computation of Uſher, the hiſtory of 2552½ years, from the beginning of the world to the death of Moſes. The word is Greek, compounded of *δευτερος*, *ſecond*, and *νομος*, *law*.

It does not appear that Moſes, who ſeems, from ſeveral paſſages that occur towards the beginning, to have been the author of this book, made any diviſion of what he wrote, into diſtinct books; or that he gave different names and titles to the different parts of his work; nor do the Jews, even at this day, diſtinguiſh them in the copies they uſe in the ſynagogues, but write them all running as one ſingle work, without any other diſtinction beſide that of little and great paraſches. It is true, in the other copies, uſed by private perſons, they are divided, into five parts, as among us; but they give them no other name but the firſt word wherewith each diviſion begins; much as we do in quoting a decree, or chapter of the canon law.

Thus the firſt part of Moſes's work they call בראשית *Bereſchit*, becauſe it begins with that word; the ſecond, they call ואלה שמות *Veelleh Schemoth*; the third, ויקרא *Vajickra*; the fourth, וידבר *Vajiedabber*; and the fifth, אלה הדברים *Elleh Haddebarim*; which is one of the firſt words thereof. This cuſtom is very ancient among the rabbins, as appears from the ancient commentaries on thoſe books, called בראשית רבה *Bereſchit Rabba*, רבה ואלה שמות *Veelleh Schemoth Rabba*, &c. from the *Prologus Galeatus* of St. Jerom. The Greeks, when they firſt tranſlated the law, gave the five parts into which it was divided, the names of Geneſis, Exodus, Leviticus, Numbers, and Deuteronomy. Accordingly the names are Greek, excepting that of Leviticus, which is Hebrew; and they expreſs what is contained in thoſe books, or at leaſt the moſt remarkable things contained therein; which is the uſual Greek manner of giving titles.

The book of Deuteronomy was ſo called, becauſe this laſt part of the work of Moſes comprehends a repetition, or recapitulation, which that legiſlator made to the Iſraelites, before his death, of the law he had before delivered to them at large: and hence Deuteronomy is ſtill called, by the rabbins, משנה *Miſchneh, repetition*; משנה תורה *Repetition of the law, ſecond law*, they likewiſe call it ספר תוכחות *the Books of Reprimands*; on account of the twenty-eighth chapter, which is full of bleſſings, promiſed to ſuch as keep the law; and of curſes, threatened to ſuch as tranſgreſs it.

The book of Deuteronomy was written in the fortieth year after the delivery from Egypt, in the country of the Moabites beyond Jordan: Moſes being then in the 120th year of his age; or in the laſt year of his life. It contains, in Hebrew,

Hebrew, eleven paraſches, though only ten in the editions of the rabbins at Venice; twenty chapters and 955 verſes. In the Greek, Latin, and other verſions, it contains thirty-four chapters: the laſt was not written by Moſes, becauſe it contains a relation of his death and burial. Some ſay it was added by Joſhua, immediately after Moſes's death; others will have it added by Ezra, which is the moſt probable opinion; who likewiſe made ſome interpolations in the book itſelf, as chap. ii. ver. 12. chap. iii. 11. and 14. Eichorn, in his "Introduction to the Old Teſtament," publiſhed at Leipzig, in four volumes, 1787—1795, conſiders this book as the work of another and later perſon than Moſes, who had ſurvived ſeveral of thoſe leaders of the people, who had been educated in the ſchools of the prophets. Dr. Kennicott, in his "State of the printed Hebrew Text of the Old Teſtament, &c:" (vol. i.) has pointed out ſeveral alterations and interpolations in this book; and reſtored the true reading, particularly in chap. xxxiii. 1—5. See PENTATEUCH.

DEUTEROPOTMI, Δευτεροποτμοι, from δευτερος, *ſecundus*, and ποτμος, *fortuna*, or *mors*, among the Athenians, a deſignation given to one who had been thought dead, and after the celebration of the funeral rites, unexpectedly recovered. It was unlawful for the deuteropotmi to enter into the temple of the Eumenides, or to be admitted to the holy rites, till after they were purified by being let through the lap of a woman's gown, that they might ſeem to be new born. Pott. Archæol. Græc. tom. i. lib. ii. cap. 4. p. 223.

DEUTEROSIS, the Greek name by which the Jews called their miſchna, or ſecond law. Deuteroſis in Greek has the ſame ſignification almoſt as miſchna in Hebrew; both ſignify an iteration. Euſebius accuſes the Jews with corrupting the true ſenſe of Scripture with the trifling explanation of their deuteroſes. Calmet, Dict. Bibl. in voc.

DEUTICHEM, or DEUTIKEM, in *Geography*, a ſmall town of Holland, in the department of Gueldre, on the Old Yſſel, famous for a conſiderable iron foundery.

DEUTSCH, NICHOLAS MANUEL, in *Biography*, an eminent artiſt, was a native of Berne, in Switzerland, and flouriſhed in 1518. He is mentioned as a celebrated painter in his time. He alſo cut on wood ſeveral of his own deſigns in a bold and free, but ſlight ſtyle; and the naked parts of his figures are ſometimes incorrect. The two following prints of this artiſt are mentioned by Strutt; *viz.* "A woman ſtanding," a middling ſize upright print, and "Several women figures in a compoſition;" alſo a middling-ſized print, lengthways. To the initials of his name and a dagger, is added the date 1518. This, ſays Strutt, is one of his neateſt and beſt engravings.

DEUTSCH EYLAU, in *Geography*. See EYLAU.

DEUTSCHBROD, *Broda Germanica*, in the Bohemian language *Brod Niemeczky*, is an ancient town of Bohemia, in the circle of Czaſlaw. It is called Deutſch, or German Brod, in contradiſtinction to Brod, or Bohemian Brod, a town in the circle of Kaurzim, in the neighbourhood of which the Huſſites ſuffered a conſiderable defeat in the year 1434.

DEUTZIA, in *Botany*, (in honour of preſident John Deutz, one of the magiſtrates of Amſterdam, a patron of Thunberg, who promoted and contributed to the expences of his botanical expedition to Japan.) Thunb. Nov. Gen. faſc. 1. 19. ic. Jap. 10. Linn. Syſt. Veg. ed. 14. 425. Schreb. 305. Willd. Sp. Pl. v. 2. 730. Juſſ. 431. Claſs and order, *Decandria Trigynia*. Nat. Ord. probably *Saxifragæ* of Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, ſomewhat bell-ſhaped, three times ſhorter than the petals, downy, with five, rarely ſix, ovate, obtuſe, upright, deciduous teeth. *Cor.* Petals five, rarely ſix, inſerted into the rim of the calyx, oblong, obtuſe, undivided, entire. *Stam.* Filaments ten, inſerted into the rim of the calyx, alternately ſhorter than the corolla, linear, with three teeth at the ſummit, of which the middle one is awl-ſhaped and bears the anther; anther globoſe, of two lobes and two cells. *Piſt.* Germen inferior, globoſe, crowned with a prominent border; ſtyles three, rarely four, ſpreading, thread-ſhaped, the length of the ſtamens; ſtigmas obtuſe. *Peric.* Capſule globoſe, truncate, the ſize of a ſmall pea, perforated, hard, rough, ſomewhat three-cornered, crowned with the hardened ſpreading baſes of the ſtyles; internally of three valves, and three, rarely four, cells, burſting finally at the baſe. *Seeds* ſeveral in each cell.

Eſſ. Ch. Calyx bell-ſhaped, five-cleft. Petals five. Filaments with three points. Capſule of three cells, crowned with the permanent ſtyles, burſting at its baſe.

Sp. D. *ſcabra*. Thunb. Jap. 185. t. 24. Willd. Sp. Pl. v. 2. 730. (Joro; Kæmpf. Amæn. 854.) Found in the mountains of Japan, flowering in May and June. It forms a ſmall branching tree like elder, with round, ſlender, purpliſh, ſomewhat hoary branches. Leaves oppoſite, moſtly ſtalked, ſimple, ovate, acute, ſerrated, veiny, very rough on both ſides with minute ſtarry briſtles. Buds of ſeveral ovate, hoary, permanent ſcales. Stipulas none. Flowers in terminal hoary panicles, white, the ſize of thoſe of the common lime tree.

Kæmpfer ſays the wood is hard, tough, and ſmooth, uſed for making cabinets and very fine bodkins; and that the inner bark, which is green and very bitter, enters into the compoſition of plaſters. Thunberg informs us that the leaves are uſed for poliſhing the articles made of the wood.

DEVUIDER, in the *Manege*, is applied to a horſe, that, upon working upon volts, makes his ſhoulders go too faſt for the croup to follow; ſo that inſtead of going upon two treads, as he ought, he endeavours to go only upon one. This comes from the reſiſtance he makes in defending againſt the heels; or from the fault of the horſe-man, who is too haſty with his hand. See HASTE.

DEUX-PONTS, in German *Zweybrück*, in Latin *Bipontium*, in *Geography*, was formerly the capital of the German duchy of the ſame name, in the circle of the Upper Rhine, which, at the peace of Luneville, was ceded to the French, together with ſeveral other countries ſituated on the weſtern ſhore of the Rhine. It conſtituted at that time part of the dominions of the elector, now king of Bavaria.

Deux-Ponts at preſent is a town of France, in the department of Mont Tonnere, chief place of a diſtrict of the ſame name, ſituated on the river Erlbach, 45 miles S. W. of Worms, 66 N. by W. of Straſburg, 57 N. E. of Metz, 63 S. W. of Mayence, N. lat. 49° 20′. It has a ſub-prefect, a court of juſtice, and a regiſter office. Its canton contains only 3 communes, and 5532 inhabitants, 4976 of whom belong to the town itſelf.

The ſoil of the diſtrict of Deux-Ponts is mountainous and not very fertile, yet it produces ſufficient food for its inhabitants. Madders and potatoes thrive well; the paſtures are excellent; there is much wood, and game in plenty. The vine grows along the banks of the river Glane. There are iron, copper, and coal mines, and a mine of agate, which contains ſtones as precious as any of the Indian agates. They are uſed for ſnuff boxes, rings, ſeals, ſleeve-buttons, &c. Contwig has a ſteel manufactory, and Hombourg a manufacture of muſlin.

The

The diſtrict of Deux-Ponts counts nine cantons, 154 communes, and 55,568 inhabitants, upon a territorial extent of 1795 kiliometres.

DEW, Deap, *ros;* water depoſited by the atmoſphere in conſequence of ſimple cooling, commonly by night, and in drops too ſmall to be viſible, until collected on the leaves of plants and other objects.

Caſaubon derives the word from the Greek *δεύω*, which is ſtrictly *I dew;* the *ω* being the perſonal pronoun ſuffixed by contraction. It is quite as probable, nevertheleſs, that a ſubſtantive, anſwering to our Angloſaxon primitive, gave riſe to this verb in the Greek.

Dew is a phenomenon proper to clear weather. It begins to be depoſited about ſun-ſet, is moſt conſtant in vallies and on plains, near rivers, and other collections of water; and abounds on thoſe parts of the ſurface which are clothed with vegetation. It is often ſuſpended when rain is approaching, as likewiſe in windy weather, and before thunder ſtorms: an unuſually copious depoſition, however, ſometimes precedes rain. In general it does not fall when a cloſe veil of clouds, however ſlight, remains over the ſky after ſun-ſet. Its approach, in the extenſive valley watered by the Thames, preſents the following appearance. After a clear warm day there is gradually formed on the horizon a continuous haze, riſing ſometimes to a conſiderable height, and often tinged by the ſetting ſun with a fine gradation of red and violet ſhades. This is the precipitated water, become faintly viſible in its deſcent. Dew is always to be found on the graſs by the time that this haze has become conſpicuous, and its abundance is proportioned to the denſity and permanence of the latter.

The quantity of dew, thus depoſited, differs conſiderably at different places, and at different ſeaſons in the ſame place; nor does it fall upon bodies of every kind indiſcriminately. In explanation of theſe phenomena, ſeveral hypotheſes have been ſuggeſted, but no ſatisfactory theory has as yet been eſtabliſhed reſpecting them. We ſhall endeavour to give our readers a clear idea of the ſubject, by ſtating whatever belongs to it in the following order. We ſhall, in the firſt place, deſcribe the facts which have been aſcertained by means of experiments and obſervations; ſecondly, we ſhall briefly mention the principal hypotheſes that have been offered for their explanation; and, laſtly, we ſhall ſubjoin ſome accounts of peculiar occurrences, which ſeem to belong to the preſent article.

1. In this iſland the dew is obſerved (like the drops of a miſſling rain upon the leaves of graſs and other vegetables, upon wood, glaſs, porcelain, &c., or upon the earth, which is thereby frequently rendered ſenſibly moiſt,) more copiouſly in ſpring and ſummer mornings; than at other times of the year. In autumn, however, and even in winter, it frequently happens, under the concurrence of particular circumſtances, that an abundant dew is depoſited in the courſe of the night.

2. In countries ſituated nearer to the equator, the dews are generally obſerved in the morning throughout the whole year; and in ſome places they are ſo very copious, as in great meaſure to ſupply the deficiency of rain, which ſeldom falls in thoſe places. But the quantity of theſe effects is not entirely proportional to the latitude, other local circumſtances concurring to their production.

3. The condenſation of the vapour which forms the dew moſtly takes place whilſt the ſun is below the horizon; but no particular experiments have been inſtituted for the purpoſe of determining whether the condenſation goes on regularly during the night, or alters its rate with any particular law. It has, however, been obſerved, that in moſt countries a conſiderable depoſition of moiſture takes place not long after the ſetting of the ſun; but ſoon after the depoſition proceeds with a ſlackening pace, until the riſing of the ſun in the morning. But the regularity of theſe effects is frequently counteracted by accidental circumſtances; ſuch as the change of wind, the preſence of clouds, &c.

4. In cloudy weather there is little or no dew depoſited. The greateſt quantity of it is obſerved in a morning ſubſequent to a clear, ſtill, and cool night, which has followed a pretty warm day.

5. Mr. Du Fay, at Paris, placed two ladders againſt one another, meeting at their upper ends, and ſpreading wide aſunder below. Their height was 32 feet. To the ſeveral ſteps of theſe he faſtened large panes of glaſs, ſo diſpoſed as not to overſhade one another. With this apparatus expoſed to the ambient air, he found that the lower ſurface of the loweſt pane of glaſs was firſt wetted with dew, then its upper ſurface, then the lower ſurface of the pane next above it was wetted, and ſo on, until all the panes to the very top of the ladders became covered with dew. He alſo tried the experiment with pieces of cloth inſtead of panes of glaſs, and the reſult was ſimilar to the above. He weighed all the pieces of cloth on the morning following their expoſure, and found that thoſe which had been placed lowermoſt, had imbibed more moiſture than thoſe which had been ſituated higher up; he owns, however, that the reſult of this experiment did not prove ſo ſatisfactory as the preceding. In general the lower parts of bodies that are expoſed to the ambient air, are firſt covered with dew.

6. Muſchenbroeck repeated the above mentioned experiments of Du Fay, with this difference however, *viz.* that he placed the ladders, &c. upon a plane covered with ſheet lead, but the experiment was attended with the like reſult.

7. By ſhaking the leaves of plants that are covered with dew, or by expoſing glaſs veſſels, or otherwiſe, the dew water may be collected, and on examination it will be found to be a pretty pure water; unleſs duſt and other accidental impurities happen to be gathered with the dew water. Some particular caſes are recorded, in which the dew was found to differ conſiderably from pure water; but thoſe accounts will be noticed hereafter.

8. The moſt ſingular phenomenon which attends this aqueous condenſation is, that the dew is not depoſited upon all kinds of ſubſtances indiſcriminately; it falls upon certain bodies much more abundantly than upon others, and upon ſome even not at all. Alſo, the very ſame bodies have been found to receive the dew in a greater or leſs degree, or not at all, according to certain circumſtances. Theſe anomalous effects not appearing at preſent reconcileable to any ſatisfactory theory, it is incumbent upon us to ſtate the principal reſults of the experiments that have been made on purpoſe by various philoſophers, in order that the ingenious reader may form whatever opinion he thinks beſt upon the ſubject.

9. The drops of dew attach themſelves to glaſs, cryſtals, and porcelain, much more readily than to other bodies; next to thoſe come the leaves of vegetables, wood, eſpecially when varniſhed, and common earthen-ware; but the dew adheres leaſt of all to all ſorts of metallic bodies.

10. Muſchenbroeck obſerved that on a leaden gutter, dew condenſed on every kind of ſubſtance, and ſo it did on a table in a certain garden. The forty-ſecond volume of the Philoſophical Tranſactions, page 112, contains ſome obſervations on dew, made by Dr. L. Stocke, upon the leaded platform of a tower. He expoſed ſeveral ſubſtances, and found, upon the whole, that the dew fell plentifully upon glaſſes of various kinds; it fell leſs copiouſly upon certain pieces of wood, and leaſt of all upon metals, excepting, however, ſuch as were

rough;

rough; for he found that much dew fell upon what he calls *ferrum aſperum*, and *plumbum aſperum*. None fell upon ruſty iron.

11. Mr. Du Fay, at Paris, made the following experiments. He placed a china ſaucer in the middle of a ſilver plate, and adjoining to it he placed a china plate, having in its middle a ſilver diſh, much reſembling the above-mentioned ſaucer. All this he expoſed to the ambient air, and found that the china ſaucer was covered with dew, whilſt the ſilver plate, which extended four inches round it, was not moiſtened in the leaſt. Alſo the china plate was covered with a conſiderable quantity of dew, whilſt the ſilver diſh in the middle of it was quite dry.

12. Mr. Du Fay, in order to determine whether the nature of the body upon which the veſſel was placed to receive the dew had any influence in the effect, employed two equal watch glaſſes, one of which he placed, with its concavity uppermoſt, upon a ſilver plate; and placed the other in a ſimilar manner upon a china plate. The firſt of theſe glaſſes was ſurrounded with a ſilver ferril, the object of which was to prevent any adheſion of dew to its convex ſurface, which faced the ſilver plate. This apparatus having been expoſed for ſeveral ſucceſſive nights, he conſtantly found five or ſix times more dew in the watch glaſs, which ſtood upon the china plate, than in that which ſtood upon ſilver. He alſo obſerved, that in the latter, the ſmall quantity of dew ſtood principally about the centre, in the form of ſmall drops, which diminiſhed in ſize as their ſituation was more remote from the centre, and left a border of about half an inch, quite dry all round the edge of the glaſs.

13. Dr. Watſon, biſhop of Landaff, relates ſome experiments performed by himſelf, the reſult of which coincides with that of the preceding paragraph. "By means," he ſays, "of a little bees-wax, I faſtened a half-crown very near, but not quite contiguous, to the ſide of the glaſs; and, ſetting the glaſs with its mouth downwards on the graſs, it preſently became covered with vapour, except that part of it which was next the half-crown. Not only the half-crown itſelf was free from vapour, but it had hindered any from ſettling on the glaſs which was near it; for there was a little ring of glaſs ſurrounding the half-crown, to the diſtance of a quarter of an inch, which was quite dry, as well as that part of the glaſs which was immediately under the half-crown; it ſeemed as if the ſilver had repelled the water to that diſtance. A large red wafer had the ſame effect as the half-crown; it was neither wetted itſelf, nor was the ring of glaſs contiguous to it wetted. A circle of white paper produced the ſame effect, ſo did ſeveral other ſubſtances, which it would be too tedious to enumerate."

14. A much more extenſive ſeries of experiments on this ſubject, the reſult of which is highly deſerving of attention, was a few years ago inſtituted by Mr. Prevoſt; and a ſummary of which is as follows. He found that when plates of metal (which he calls armours) are fixed on pieces of glaſs, it ſometimes happens that they are as much covered with dew as the glaſs itſelf; but more frequently they remain dry, and in this caſe they are alſo ſurrounded by a dry zone. But when the other ſide of the glaſs is expoſed to dew, the part which is oppoſite to the metal remains perfectly dry. If the metal be again covered with glaſs, it will loſe its effect in preventing the depoſition.

15. Theſe experiments may be very conveniently made on the glaſſes of a window, when moiſture is attaching itſelf to either of its ſurfaces. Mr. Prevoſt remarks that it often happens that dew is depoſited externally, even when the air within is warmer than without. A plate of metal fixed internally on a window, receives a larger quantity of moiſture than the glaſs, while the ſpace oppoſite to an external plate remains dry; and if the humidity is depoſited from without, the place oppoſite the internal plate is alſo more moiſtened, while the external plate remains dry; and both theſe circumſtances may happen at once with the ſame reſult. A ſmall plate fixed externally, oppoſite to the middle of the internal plate, protects this part of the plate from receiving moiſture, and a ſmaller piece of glaſs fixed on the external plate, produces again a central ſpot of moiſture on the internal one; and the ſame changes may be continued for a number of alternations, until the whole thickneſs exceeds half an inch.

16. Gilt paper, with its metallic ſurface expoſed, acts as a metal; but when the paper only is expoſed, it has no effect.

17. When a plate of metal, on which moiſture would have been depoſited, is fixed at a ſmall diſtance from the glaſs, the moiſture is transferred to the ſurface of the glaſs immediately under it, without affecting the metal. If this plate is varniſhed on the ſurface remote from the glaſs, the effect remains, but if on the ſide next the glaſs, it is deſtroyed.

18. The oxydation of metals renders them alſo unfit for the experiment. When glaſſes, partly filled with mercury, or even with water, are expoſed to the dew, the latter is depoſited only on the parts which are above the ſurface of the fluid. But in all caſes when the humidity is too copious, the reſults are confuſed.

19. In order to reduce theſe facts to ſome general law, Mr. Prevoſt obſerves, that when the metal is placed on the warmer ſide of the glaſs, the humidity is depoſited more copiouſly either on itſelf, or on either ſurface of the glaſs in its neighbourhood; but that when it is on the colder ſide, it neither receives humidity, nor permits its depoſition on the glaſs. That a coat of glaſs or varniſh deſtroys the efficacy of the metal, but that an additional plate of metal reſtores it.

20. The quantity of water which falls upon the ſurface of the earth in the form of dew, has by no means been aſcertained either in this country or elſewhere; nor does it appear eaſy to deviſe means of aſcertaining it. Dr. Hales relates ſome experiments he made with a view of determining the quantity of dew which falls in the night. For this purpoſe, Aug. 15, 7 P. M. he filled two glazed earthen pans, three inches deep, and twelve inches diameter in ſurface, with moiſt earth: and he obſerves, that the moiſter the earth, the more dew falls on it in a night; and that more than a double quantity of dew falls on a ſurface of water, than on an equal ſurface of moiſt earth. Theſe pans increaſed in weight by the night's dew 180 grains; and decreaſed in weight by the evaporation of the day, 1 ounce, 282 grains; ſo that 540 grains more are evaporated from the earth every 24 hours in ſummer, than the dew that falls in the night; *i. e.* in 21 days near 26 ounces from a circular area of a foot diameter. If 180 grains of dew, falling in a night on ſuch an area, which is equal to 113 ſquare inches, be equally ſpread on the ſurface, its depth will be $\frac{1}{159}$th part of an inch, $= \frac{180}{113 \times 254}$. He likewiſe found the depth of dew in a winter's night to be the $\frac{1}{90}$th part of an inch. If, therefore, we allow 159 nights for the extent of the ſummer's dew, it will in that time ariſe to one inch depth; and reckoning the remaining 206 nights for the extent of the winter's dew, it will produce 2.28 inches deep; and the dew of the whole year will amount to 3.28 inches depth. But the quantity, which evaporated in a fair ſummer's day from the ſame ſurface,

pendicularly, or at leaſt very nearly ſo to the lines of defence. For when an enemy once makes a lodgment on the counter-ſcarp, he will diſcover them whether they be ſo placed or not. And if flanks be diſcovered, they alſo diſcover, and being either reveted or demi-reveted and formed of earth that is well ſettled, they are by no means ſo eaſily ruined as the batteries of the beſiegers, which are formed of gabions and newly raiſed earth.

Count Pagan's method of conſtruction on a polygon, (*fig.* 2.) is widely different from that of Errard, and alſo much preferable. For inſtead of making the angle of the flank acute in the octagon and figures of a ſmaller number of ſides, and only equal to a right one in any polygon of a greater number of ſides, as Errard does, he makes it obtuſe and places his flanks perpendicularly to the lines of defence, in order that they may diſcover more ground, and the better raſe and defend the faces of the baſtions, which are the moſt ſaliant and weakeſt parts of the body of the place and are firſt attacked, breaches being commonly made in them. This ingenious author makes his lines of defence like Errard's, always raſant, but does not like him make 90 degrees the maximum of his flanked angle, or angle of his baſtion.

He delivers conſtructions for three ſorts of fortifications, namely, the great, the mean, and the little. He fortifies or conſtructs inwards, and in the great fortification makes the exterior ſide equal to 200 toiſes, in the mean equal to 180 toiſes, and in the little equal to 160 toiſes. He allows 60 toiſes to each face of a baſtion in the great, 55 in the mean, and 50 in the little, in all figures above a ſquare. He makes the perpendicular to the exterior ſide in the great fortification in all figures, except the ſquare where it is 27 toiſes, equal to 30 toiſes; in the mean equal to 24 toiſes; and in the little equal to 21.

The dimenſions of theſe principal lines in theſe three kinds of fortification, are contained in the following Table.

	Great Fortification.		*Mean.*		*Little.*	
	Square.	In all other Polygons.	Square.	In all other Polygons.	Square.	In all other Polygons.
Exterior Sides.	200	200	180	180	160	160
Perpendiculars.	27	30	24	30	21	30
Faces of baſtions	60	60	55	55	45	50

Suppoſing then the exterior ſide A B, (ſee the figure,) equal to 200 toiſes in the great, to 180 in the mean, and to 160 in the little, biſect it in the point C. In C O, which is perpendicular to A B, take C D equal to 30 toiſes, in all regular figures of a greater number of ſides than four. Through the point D, draw the lines of defence A D H, B D G, on which take A E and B F, each equal to 60 toiſes in the great fortification, to 55 in the mean, and to 50 in the little. Then draw the flanks E G, F H, perpendicularly to the raſant lines or lines of defence B G, A H, and form the curtain by joining the points G, H. This is Count Pagan's conſtruction, without orillons and retired flanks.

The figure is a regular hexagon, ſuppoſed to have each of its ſides equal to 180 toiſes, as in his mean fortification. The angle A O B of the centre is therefore equal to 60 degrees, and the angle of the polygon to 120. A C, or B C, is equal to 90 toiſes, the perpendicular C D is equal to 30, and the face A E, or B F, to 55 by conſtruction.

Now by means of theſe lines and angles, the others are eaſily found. And in the firſt place, the angle *diminué* C A D, or the angle formed by the exterior ſide A B, and the line of defence A H, is formed by the following analogy,

As A C, equal to 90 toiſes,
Is to C D, equal to 30 toiſes,
So is radius
To the tangent of the angle C A D = 18° 26′ 6″ very nearly. If this angle be taken from 60 degrees, half the angle of the polygon, we get the angle O A H, or M A E, equal to 41° 33′ 54″. But this is equal to half the ſaliant angle of the baſtion, wherefore the whole flanked angle or angle of the baſtion is equal to 83° 7′ 48″. And the flanking angle A D B, being equal to the exceſs of 180 degrees above twice the angle *diminué*, is evidently equal to 143° 7′ 48″.

The tenaille A D, being equal to $\sqrt{AC^2+CD^2}$, is $= \sqrt{9000} = 10\sqrt{90} = 94.868329805$ nearly. Or it is found by this analogy.

As radius
Is to the ſecant of the angle *diminué* C A D,
So is A C, half the exterior ſide A B,
To the tenaille A D.

If from this there be taken the face A E, which is equal by conſtruction to 55 toiſes, we get the right line D E, and the following analogy for the flank E G.

As radius
Is to the ſine of double the angle *diminué* C A D,
So is the right line D E
To the flank E G.

And as the angle A E G of the epaule or ſhoulder is always, in regular conſtruction, equal to twice the angle *diminué* C A D, and the angle E G B formed by the flank and line of defence, the angle D E G is known, and D G is aſcertained by the following analogy.

As radius
Is to the ſine of the angle D E G,
So is the right line D E
To the right line D G.

The angle E G H of the flank, is in this conſtruction equal to 90 degrees, together with the angle *diminué*, or the angle formed by the exterior ſide, and one of the lines of defence.

The complement, D G, or D H, being thus found, the curtain G H is aſcertained by the following analogy.

As the ſine of the angle *diminué* D G H
Is to the ſine of double the ſaid angle,
So is the complement D G
To the curtain G H.

The lengthened curtain M H, or G N, is determined by the following analogy.

As the ſine of half the angle of the polygon
Is to the ſine of half the flanked angle,
So is the raſant line, or line of defence A H,
To the lengthened curtain M H. From which, and the curtain G H, the inward or interior ſide M N is immediately obtained.

And the capital A M is aſcertained by this analogy.

As the ſine of half the angle of the polygon
Is to the ſine of the angle *diminué*,
So is the raſant line, or line of defence A H,
To the capital A M of the baſtion.

It is manifeſt from the foregoing table, that the perpendicular in this learned and judicious author's great fortification, ſubtends in the ſquare an angle of about 15° 6′ 34″ nearly, and in all other regular figures of about 16° 41′ 57″ nearly; that in his mean fortification it ſubtends in the ſquare an angle of about

Baſes of the Explanation.

1. "The leſs the temperature of glaſs is elevated, the more humidity it attracts from the air."

2. "Metals attract it very little."

3. "Glaſs ſenſibly exerciſes its action on the humidity of the air, at a diſtance, and notwithſtanding the interpoſition of different bodies, ſuch as plates of metal, &c."

4. "Metals give to glaſs, near which they are placed, the property of more ſpeedily attracting caloric from hot air, and on the contrary, that of yielding it more ſpeedily to cold air."

N. B. "When I ſay that metals give glaſs this property, I mean that *they act as if they gave it;* which is evident by an examination of two thermometers, one of mercury, the other of alcohol, which are plunged at the ſame time in air either colder or warmer than that whoſe temperature they indicate. The metallic thermometer arrives much ſooner than the other to that of the new medium. Its glaſs then, if colder, muſt take up more ſpeedily from the medium the caloric which it tranſmits to the metal, or, if hotter, it muſt more ſpeedily give out that of the metal. This being premiſed, it is eaſy to comprehend that," "when the glaſs is armed on its warm face (§ 19.), it yields its caloric to the cold air more ſpeedily than that which is not armed (baſis 4.), and, conſequently, it attracts humidity more powerfully (baſis 1.), whether directly on the glaſs, or through the metal, or on the metal itſelf (baſis 3.), if this be in contact; but if it be at the diſtance of ſome millimetres, the humidity not meeting the metal on its paſſage, accumulates on the oppoſite glaſs in a greater quantity than elſewhere."

"If the metal be applied on the cold ſide (§ 19.), the glaſs moſt heated does not attract ſo much humidity (baſes 4 and 1.), and it accumulates on the unarmed part of the pane."

"If, in this caſe, the armour be covered with a plate of glaſs, the plate cools more ſpeedily than if the metal were not preſent; but as the partition is more heated than if it were not preſent, there is no effect, and the totality of the double glaſs armed within, is in the ſame caſe with that unarmed; it, therefore, accumulates neither more nor leſs humidity."

"A ſecond armour on the plate of glaſs will cauſe the phenomena to re-appear (§ 19.); and a ſecond plate of glaſs on this new armour will again make them diſappear, &c. (§ 15.) For, as long as the ſymmetrical glaſs ſhall have the interior armours, the cauſes of heat and cold will be found in equilibrio; but an additional armour will neceſſarily deſtroy the balance, and the heated glaſs will not attract humidity."

"If the glaſs be armed on both ſides (§ 15.), as it would not then be expoſed to the air, either on the cold or warm ſide, it ſeems that it ought to attract as much humidity on the armours, as on the reſt of the partition. But though the glaſs exerciſes its action through the metal, this is, nevertheleſs, an obſtacle which diminiſhes its force; humidity, in this caſe, will not then be ſo ſtrongly attracted by the doubly armed glaſs, as by the part perfectly unarmed, &c."

Mr. Prevoſt concludes with ſaying, "Theſe obſervations are not only intereſting, but they appear to eſtabliſh an important point in philoſophy; namely, that glaſs exerciſes its attraction for the humidity (which has a tendency to be depoſited from the air) through metals."

The French have, in common language, two different terms whereby to expreſs the evening and morning dew, calling the one *ſerein*, the other *roſée*; and, whether miſled by this peculiar nomenclature, or guided by more accurate obſervation, a modern chemiſt, C. A. Prieur, gives a very different account of the matter. "I was well aware," ſays he, ſpeaking of the circumſtances which led him to inveſtigate the ſubject, "that the moiſture depoſited on bodies, ſoon after ſun-ſet, is not the ſame with that which we find on them again at ſun-riſe. There is *conſequently* an interruption in the phenomenon, an evaporation of the *ſerein*, or evening dew, and a new production in the morning. It is uſual to explain the evening dew, by ſaying that the air, being then cooled, can no longer retain the water it has diſſolved in the day. But whence ariſes the breeze, which conſtantly blows from the ſun's place, during the precipitation of this water; and why does that luminary, in re-appearing on the horizon, give occaſion to a ſtill ſtronger breeze, to a greater degree of cold, and a more abundant production of dew?" (Annales de Chimie, tom. 28. p. 317.) Some important points of fact, thus taken for granted, this philoſopher proceeds to give a theory of the dew, conſidered generally, and with reſpect to the whole ſurface of the earth, of which we ſhall briefly ſtate the ſubſtance.

If the earth were deprived of its diurnal motion, and thus expoſed to the action of the ſun, the following might be conceived to be the effects of that action, in relation to the preſent ſubject. A large ſpace, immediately beneath the ſun, would be ſubject to continued evaporation, ſo long as there remained any water to be dried up. The air, charged with water, would paſs off above in all directions, towards the fixed horizon, or the boundary between the light and dark ſides of the globe; while its place would be ſupplied by freſh air flowing in beneath. In proportion as the vapourized air became cooler, in receding from the ſun, it would let fall its water in the form of dew. There would, conſequently, be a certain zone, or tract of the ſurface, perpetually ſubjected to the fall of dew, brought by a wind coming from the ſun. There would alſo be a ſpace turned directly towards the ſun, where dew would never fall, becauſe of the conſtant evaporation; and another ſpace, turned directly from the ſun, to which it would never reach from the heated ſpace, and in which evaporation could never take place to produce it. By combining this ſuppoſed circulation of the air with the actual ſtate of things, in other reſpects, Prieur attempts to ſhew why the fall of dew in the evening is accompanied with a weſterly breeze, and ceaſes before midnight; why the depoſition is renewed in the morning with a wind from the eaſtward; and why dew falls more copiouſly at ſun-riſe than at ſun-ſet; and beneath the torrid zone, than in the neighbourhood of the poles. He affirms, on this point, that in Egypt, in Aſiatic Turkey, at the Antilles, and in Mexico, the morning and evening dews wet the bodies expoſed to them, as effectually as a ſhower of rain; which, however, commonly happens in many parts of England. This hypotheſis, though undoubtedly more ingenious than ſolid, ought to have led to a more accurate examination of the truth of the ſuppoſitions on which it is founded. On the continent of Europe there may be ſituations in which the phenomena, aſſumed by Prieur, are more conſtant and diſtinguiſhable than in Britain, where we do not find that their occurrence has been ſufficiently marked.

The production of dew is admitted, on all ſides, to be a conſequence of the nocturnal refrigeration of the atmoſphere. Now it is a fact eſtabliſhed, by the obſervations of different meteorologiſts, that this refrigeration, after a clear day, begins near the ſurface of the earth, and proceeds upward. Yet it ſhould ſeem that the caloric eſcapes, not into the earth, but into the ſuperior atmoſphere: for the effect is ſometimes carried on to a much lower temperature than that of the earth's ſurface; and the denſe clouds, which

have

have ſubſiſted through the heat of the day, very commonly, in fair weather, break up and evaporate in the evening, at the time that dew is forming below; ſhewing that the region in which they are placed is growing warmer. Such, then, being the law of the nocturnal refrigeration, it follows that the loweſt ſtratum of the atmoſphere, ſeated over waters and in vallies, ought to be the firſt to part with its exceſs of water. When the air about ſunſet is very calm, the progreſs of the precipitation upwards may be ſo gradual as to admit of a definite boundary; ſo that, at a certain height from the ground, there ſhall be already ſmall drops floating in the air, and attaching themſelves to the bodies near them, while at only a foot higher, the vapour has not yet begun to be decompoſed. This may ſerve to account for the facts ſtated by Du Fay. At the ſame time, when the cooling has proceeded ſo far, as to affect a conſiderable portion of the atmoſphere, it cannot be doubted that the drops may deſcend at certain times, and in certain ſituations, from a height even of ſome hundred feet; as may be concluded from the appearance of the haze we have mentioned.

According to the hypotheſis of Prieur, dew ought to fall over the whole ſurface, without regard to hill or valley. By the explanation above given, it ought to be rare on the hills, which is the fact; for the difference between the diurnal and nocturnal temperature is there neither ſo conſiderable, nor ſo ſuddenly produced: indeed they are ſubject, if of great height, to the effect of the heat aſcending from the vallies into the atmoſphere around them, as above deſcribed.

The name of dew has likewiſe been applied to other things, which either ſeem to have been depoſited from the atmoſphere upon terreſtrial bodies at particular times, or may have ſome diſtant connection with the common dew.

It is recorded in one of the firſt numbers of the Philoſophical Tranſactions, that in the year 1695, there fell in Ireland, and particularly in the provinces of Leinſter and Munſter, during a great part of the winter and ſpring, a fatty ſubſtance, ſomewhat like butter, inſtead of the uſual dew. This ſubſtance is ſaid to have been of a dark yellow colour, and felt clammy, whence the natives called it *dew-butter*. It fell in the courſe of the night on the mooriſh low grounds; and it was found, in the morning, attached to the leaves of graſs, to the thatches of houſes, &c. in the form of pretty large lumps, and it is added, that it ſeldom fell twice in the ſame place. It had an offenſive ſmell, like that of a churchyard; yet it lay upon the ground a fortnight before it changed colour, after which it dried up and became black; but it never bred worms, nor did it prove noxious to cattle that fed in the fields where it fell. During the winter of the above-mentioned year, ſome very ſtinking fogs were obſerved on the ſame places where the *dew-butter* fell.

During a great part of the year 1783, (in which the repeated earthquakes of Calabria and Sicily deſtroyed almoſt the whole of the former and a great part of the latter place; when a very large meteor was obſerved in the month of September by moſt European countries, and when the Hecla in Ireland made a vaſt eruption of ignited matter) it is ſaid that many perſons obſerved a peculiar kind of clammineſs upon the leaves of trees, as if a dew of a glutinous nature had been depoſited from the atmoſphere; but we do not find that any particular experiments were made for the purpoſe of aſcertaining the nature of it.

The May-dew acquired conſiderable celebrity amongſt the learned perſons of a century or two ago, and many wonderful properties are attributed to it, and eſpecially to a ſpirit which is ſaid to be obtainable from it. But it is needleſs to recite particulars, claiming little or no credit. See Phil. Tranſ for May 1665.

Dew, *Honey*. This is a ſweet viſcid liquor, found ſometimes in great abundance on the hazel, the lime, the elm, &c. and on fruit trees. Some have ſuppoſed it a depoſition from the atmoſphere, as is evident by the name of dew being given to it: others have thought it the juice of the plant, ſecreted in conſequence of an injury, ſuſtained by ſudden changes in the air. To aſcertain its real origin, we have only to ſearch the under-ſurface of the leaves, immediately over thoſe on which it appears. They will be found covered with an inſect, of the genus *Aphis*, which, inſerting its probóſcis into the fine ſap veſſels, draws out the ſap, and by a peculiarity of conſtitution rejects, in the form of excrement, a product abundantly more rich and ſaccharine than the liquid it imbibes. See Aphis.

Dew, *Orange*. See Orange.

Dew, *Sun*. See Sun-*Dew*.

Dew, *Earth of*. See Earth.

Dew-*Born*, in the *Management of Cattle*, an exceſſive ſwelling of the body, proceeding from the greedineſs of a beaſt to feed, when put into rank paſture.

This ſwelling is often ſo great, that the creature runs the utmoſt hazard of burſting; in which caſe it ſhould be made to ſtir much, and purge well; but the proper cure is to bleed the creature in the tail, then putting a nutmeg into an egg, to thruſt it down the creature's throat, ſhell and all; after which, by walking him up and down, he will ſoon recover.

Dew-*Lap*, in *Rural Economy*, a name applied to the fleſhy membranous ſubſtance, which hangs down from the throats of cattle of the neat kind.

DEWAERT, in *Geography*, an inconſiderable iſland, lying at ſome diſtance E. of Terra Magellanica, in South America; ſo called from its firſt diſcoverer.

DEWAH, or Gogra, a river of Hindooſtan, which traverſes the country of Oude, and joins the Ganges; fifteen miles W. of Patna.

DEWBERRY Bush, in *Botany*. See Rubus.

DEWEE, in *Geography*, an iſland in South Carolina, which forms one of the three harbours of the city of Charleſtown.

D'EWES, *Sir* Symonds, in *Biography*, an induſtrious antiquary, born at Coxden, in the county of Dorſet, in the year 1602. He finiſhed his ſtudies at St. John's College, Cambridge, and began at an early age to make collections of materials for the hiſtory of his country. At the age of thirty he had completed his principal work, *viz.* the Journals of the Parliaments under Elizabeth, and had in his inquiries been enabled, according to his own account, to correct Camden's Britannia in almoſt every page. He was appointed high-ſheriff for the county of Suffolk in the year 1639, having been previouſly honoured with knighthood. In the following year he was elected repreſentative for the borough of Sudbury, in the long parliament. Sir Symonds was created a baronet in 1641; he, however, adhered to the parliament, and took the ſolemn league and covenant. In "the purge" of 1648, he was expelled the houſe, and from that period, to his death in 1650, he devoted himſelf to a retired and literary life, employing himſelf in copying records and other ancient documents, and in collecting coins and manuſcripts. The only work by which this author is remembered, has already been noticed. This was reviſed and publiſhed by Paul Bowes, eſq. in the year 1682. Several of his MS. collections, and a number of letters that paſſed between him and his antiquarian friends, are preſerved in the Britiſh Muſæum. Biog. Brit.

DEWIT, or De Wit, Jaques, a painter of hiſtory and portrait, was born at Amſterdam in 1695, and acquired the principles of his art from Albert Spiers, a portrait painter. He afterwards became a diſciple of Jacques Van Halen, an hiſtorical painter of conſiderable reputation; under whoſe inſtructions he made great improvement, particularly by copying ſome capital paintings of Rubens and Vandyck. In 1713, he obtained the firſt prize in the Academy, for deſigning after a living model, and the firſt prize for painting hiſtory; and he became more known by ſketching ſeveral of the cielings in the Jeſuits' church at Antwerp, originally painted by Rubens and Vandyck, which had been much injured by lightning. He declined the painting of portraits, though much ſolicited to engage in this branch of his art, and chiefly reſtricted himſelf to the painting of cielings and grand apartments, in which he excelled by an elegance of taſte, and tolerable correctneſs of deſign. His moſt noted work was for the burgo-maſters of Amſterdam, in their great council-chamber; in which he choſe for his ſubject Moſes appointing the 70 elders, and which he executed in a manner highly honourable to him as an artiſt. Without ever having ſeen Rome, he acquired the ſtyle of the Italian maſters, by ſtudying after the fineſt deſigns of the beſt artiſts of that country, which he collected with great judgment and expence. The colouring of Dewit is extremely good, and his compoſitions are grand and pleaſing; his pencil is free, and his touch abounds with ſpirit and brilliancy; and a better taſte of deſign would have rendered him truly eminent. But his ſingular excellence conſiſted in his imitations of bas-relief in ſtone, wood, or plaſter, which he painted both in oil and in freſco, ſo as to give them the appearance of real carvings. His ſketches, though ſlight, are much admired for their freedom and ſpirit, and are purchaſed by perſons of the beſt taſte. This artiſt, who died at Amſterdam, in 1754, etched, from his own deſigns, a ſet of ſix ſmall plates, repreſenting "groups of boys," which are executed in a very ſpirited ſtyle; and the "Virgin and Child." Pilkington. Strutt.

DE WITT, John, the celebrated Dutch penſionary, was born at Dort, where he was educated. He exhibited a ſtrong taſte for mathematical ſtudies, and publiſhed, when he was only twenty-three years of age, a work of conſiderable reputation, entitled "Elementa Curvarum Linearum." In the year 1650, he was choſen penſionary of Dort, and ſoon diſtinguiſhed himſelf as an able politician, and upright ſtateſman. He was the advocate of peace, and oppoſed very ſtrenuouſly the war between the Engliſh and Dutch. He was afterwards ſucceſsful in effecting a peace with Cromwell. In this treaty was inſerted a ſecret article for excluding the houſe of Orange, which rendered De Witt very unpopular. He was, however, re-elected penſionary of Holland in 1663. In the war with England, which broke out ſoon after this, he was appointed one of the commiſſioners to direct the navy, and afterwards appointed, with two others, to the command of the fleet; for his great ſervices in this particular, and likewiſe as penſionary, he merited and received the thanks of the ſtates-general. He afterwards fell into diſgrace: by a courageous defence of his own ſyſtem of liberty, and by oppoſing the repeal of the perpetual edict with reſpect to the ſtadtholderſhip, he became the object of horror to the Dutch populace, who conceived that their exiſtence depended upon a ſtadtholder. De Witt was attacked by four aſſaſſins, who wounded him, and left him for dead in the ſtreet. His brother Cornelius at this time was falſely accuſed of an attempt on the life of the prince of Orange. The only witneſs was a barber of infamous character. The puſillanimous judges did not dare to oppoſe the prevailing and popular cry: they condemned him to "ſuffer the queſtion." This man, who had bravely ſerved his country in war, and who had been inveſted with the higheſt dignities, was delivered into the hands of the executioner, and almoſt torn in pieces by the ſevereſt and moſt ſavage tortures. In the midſt of his agonies, he repeated, as applicable to himſelf, the ode of Horace.

"Juſtum et tenacem propoſiti virum," &c.

His life was ſpared, and he was condemned by the judges, who have ever been held up to public infamy, to baniſhment. The penſionary, who had not been prevented from performing the part of an affectionate brother and faithful friend, during this proſecution, reſolved not to deſert him on account of the unmerited ſufferings which he had endured. He followed him to priſon, and reſolved to accompany him to the place of his exile. A ſignal was given to the populace: they roſe in arms, broke open the priſon doors, dragged away the two brothers, and a thouſand ſavage hands vied with each other who ſhould be the firſt and deepeſt ſtained with the innocent blood of theſe uncorrupted, and incorruptible patriots. The brutal wretches were not ſatisfied even with their lives: on their dead bodies they exerciſed every indignity, which monſters in the ſhape of men could invent and deviſe. Thus ended the De Witts, whoſe actions will be more particularly noticed under the article United States. The penſionary, to whom this article is chiefly devoted, is deſcribed by Mr. Hume as "a miniſter equally eminent for greatneſs of mind, for capacity, and for integrity. Though moderate in his private deportment, he knew how to adopt in his public councils that magnanimity which ſuits the miniſter of a great ſtate. It was ever his maxim, that no independent government ſhould yield to another any evident point of reaſon or equity; and that all ſuch conceſſions, ſo far from preventing war, ſerved no other purpoſe than to provoke freſh claims and inſults." Hume's Hiſt.

DE WITTSBURGH, in *Geography*, a town of America, in the ſtate of New York, on the Suſquehana; 155 miles N.W. of New York.

DEX, a name uſed by many Greek writers for a worm or maggot, hatched of the egg of a beetle, and remarkable for its eroding wood. It is alſo called thrips and enxylon. The old Greeks uſed the pieces of wood eroded by it in various directions as ſeals. See Thrips.

DEXTANS, in *Antiquity*. See As.

DEXTER, in *Heraldry*, is applied to the right ſide, as ſiniſter is to the left.

The word is pure Latin, ſignifying right-handed; whence the word dexterity for addreſs and ability in the performing of any thing.

Dexter-*baſe*, is the right ſide of the baſe.

Dexter-*chief*, the angle on the right hand of the chief.

Dexter-*point*. See Point.

DEXTRARIUS, is underſtood of one who takes the right hand of another; and the word dextrarii has been uſed for light horſes, or horſes for the great ſaddle; from the French deſtrier, a horſe for ſervice.

DEXTROCHERE, or Destrochere, in *Heraldry*, is applied to the right-arm painted on a ſhield, ſometimes naked, ſometimes clothed, or adorned with a bracelet, and ſometimes armed, or holding ſome moveable, or member uſed in the arms.

The word is formed from the Latin dextrocherium, which ſignifies a bracelet worn on the right wriſt, mentioned in the Acts of the Martyrdom of St. Agnes, and the Life of the Emperor Maximus.

The dextrochere is ſometimes placed at the creſt.

DEY, the title of the ſovereign of Algiers, under the protection of the grand ſeignior, called at Tunis the bey. A prince under this title was appointed by the ſultan, at the requeſt of the Turkiſh ſoldiers, in the year 1710. The term dey, in the Turkiſh language, ſignifies an uncle by the mother's ſide; and the reaſon of the denomination is this; that the Turkiſh military conſider the grand ſeignior as their father, the republic as their mother, by which they are nouriſhed and maintained, and the dey as the brother of the republic, and conſequently the uncle of all who are under his dominion.

The dey is choſen out of the army; each order, even the moſt inferior, having an equal right and title to that dignity with the higheſt. Every bold and aſpiring ſoldier, however obſcure his original and rank, may be conſidered as the heir apparent to the throne; and with this farther advantage, that he lies under no neceſſity to wait till ſickneſs or old age has removed the preſent ruler; it is ſufficient that he can protect himſelf with the ſame ſcymitar, which he has ſheathed in the breaſt of his predeceſſor. As the chief command (ſuch was the caſe at the time when Dr. Shaw viſited this country) lies open to every bold pretender, the deys rapidly ſucceed one another; one in ten having rarely had the fortune to die in his bed; *i. e.* without a muſket-ball or ſcymitar. Thoſe few, who have thus peaceably departed, cannot attritbute it to any ſuperior regard and eſteem which the army had for them in particular, but rather to their own ſuperior good fortune, in preventing an inſurrection, by cutting off the conſpirators before they could put their deſigns in execution. Beſides the age, experience, and valour, which are neceſſary qualifications of a perſon to be elected to the office of dey, he muſt alſo be a native Turk, and have made the voyage to Mecca. He has no guards, nor conſiderable retinue; he preſides at the divan, and is moſt diſtinguiſhed by the reſpect and ſubmiſſion which are paid him.

DEYDESHEIM, or DIDINESHEIM, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and biſhopric of Spire; 14 miles W. of Spire.

DEYNSE. See DEINSE.

DEYNUM, JOHN BAPTIST VAN, in *Biography*, was born at Antwerp in 1620, and devoted the early period of his life to the ſtudy and practice of the art of painting; in which he arrived at diſtinguiſhed excellence. His ſubjects were portraits in miniature, and alſo hiſtory and landſcapes in water-colours, which he executed with ſurpriſing neatneſs, judgment, and taſte. His works, moſt of which were purchaſed by the emperor and the king of Spain, were admired for the delicacy of his touch, for the ſweetneſs of his colouring, for the exquiſite manner in which they were finiſhed, and alſo for elegance of compoſition. Pilkington.

DEYSTER, LEWIS, an hiſtorical painter, was born at Bruges in 1656, and became a diſciple of John Maes, a painter of portrait and hiſtory: but perfected himſelf in deſign and colouring by the ſtudy of the antiques, and of the beſt modern productions at Rome for ſix years, and by copying and examining the beautiful compoſitions of the Venetian artiſts for ſix years more at Venice. His diſpoſition led him to ſeclude himſelf from public notice, after his return to his own country; but ſeveral performances for the public, in which he engaged, made him more known, and enriched him, while they raiſed his reputation. At Bruges he painted two excellent pictures; *viz.* "Rebecca with Abraham's ſervant at the well," and "Judith and Holophernes." But his moſt capital performances are "The death of the Virgin," and the "Reſurrection of Chriſt, with the appearing of Chriſt to Mary Magdalen, and the other Mary," in which the figure of our Saviour is accounted in no reſpect inferior to Vandyck, either in colouring or deſign.

He painted in the grand ſtyle, and much in the taſte of the Italian ſchool; he gave much elegance to the airs of his heads, and to the extremities of his figures; his draperies are looſe and light; his colouring is warm; and the ſhadows were only glazed in the finiſhing, with a compoſition called "ſphaltum." This artiſt died in 1711. His daughter, Anna, who died in 1746, aged 50, painted in the ſtyle and manner of her father, and imitated his touch and colouring ſo exactly in the copies after her father's works, that the ableſt judges could not poſitively diſtinguiſh the copies from the originals. Pilkington.

DEZAIGNE, in *Geography*, a ſmall town of France, in the department of the Ardêche; 12 miles W. of Annonay.

DEZALLIER, D'ARGENVILLE, ANTONY-JOSEPH, in *Biography*, was born at Paris in the beginning of the laſt century. He was educated in his native city, but a conſiderable time after this he ſpent in foreign countries, particularly in Italy, where he formed a taſte for the fine arts. He became acquainted with men of ſcience in various parts of Europe, and was elected member of the Royal Society in London, and of the Academy of Sciences at Montpelier. He wrote ſome conſiderable articles in the French Encyclopedia; and in 1747 he publiſhed, in quarto, a treatiſe on the theory and practice of gardening, and in 1757 a larger treatiſe on Conchology, in two volumes quarto. This is ſaid to be his moſt valuable work. His arrangement is made from the external form of ſhells, according to which he claſſes them as univalve, bivalve, and multivalve: he then divides them again into ſhells of the ſea; of freſh water; and of the lands. He alſo gave an account of the ſeveral genera of animals that inhabit ſhells. He publiſhed a work on oryctology, or a treatiſe on foſſils. Perhaps his moſt conſiderable literary production was a biography of celebrated painters, which was publiſhed in three volumes quarto, and likewiſe in four volumes octavo. He died at Paris in 1766; and his ſon has continued the biography began by the father by the addition of two volumes, containing the lives of architects and ſculptors. Gen. Dict.

DEZIZE, in *Geography*, a town of Egypt, on the Nile, ſuppoſed to be the place where the prophet Jeremiah was buried, near Cairo.

DEZKAK, a town of Perſia, in the province of Segeſtan, 110 miles E. N. E. of Zareng.

DEZNY, or DESNY, a ſmall town of Bohemia, in the circle of Bechin, or Bechynoko, remarkable for its excellent mineral waters.

DEJEFAN, a town of Arabia, in the country of Yemen, ſituated on the coaſt of the Red ſea; 22 miles W. of Abu-Ariſch.

DGIARON, a town of Perſia, in the province of Farſiſtan; 84 miles S. of Schiras.

DHAR, a town of Hindooſtan, in the country of Malwa; 42 miles W. of Indore, and 36 S. S. W. of Oudein.

DHARAMSALEH, a town of the country of Tnibet, 60 miles from Serangpour.

DHAUN. See DAUHN, or DAUN.

DHOOLPOUR, a town of Hindooſtan, in the country of Agra; 32 miles S. of Agra.

DHUL, or DUL, a lake of Aſia, in the country of Caſhmere; five miles N. E. of Caſhmere. One branch of the Baghyretty river is ſaid to proceed from this lake above Caſhmere; but Mr. Rennell obſerves, that as this lake has no outlet on the eaſt, from the valley of Caſhmere, every branch of the Ganges that comes from the north-weſt

north-weſt muſt, of courſe, ſpring from the mountains that lie on the eaſt of Caſhmere.

DHUY, a ſmall town of France, in the department of Sambre and Meuſe, diſtrict of Namur, with a population of 520 individuals. It is the chief place of a canton which upon a territorial extent of 152½ kiliometres, comprizes 31 communes and 10,258 inhabitants.

DIA, Δια, the beginning of divers terms in medicine, chirurgery, pharmacy, &c, Where theſe three letters commence the name of a remedy, unguent, plaſter, cataplaſm &c. they ſignify compoſition and mixture; as in diapaſma, diachylon, &c.

Dia is likewiſe the beginning of many terms in the other arts: as diameter, dialogue, &c. on all which occaſions, dia, which is an inſeparable particle, or prepoſition, is borrowed from the Greek δια, *ex*, or *cum*; which begins the ſame words iu the Greek.

Indeed we have words wherein dia is no prepoſition borrowed from a foreign language; though it is poſſible, the words themſelves may; as in diamond, dial, &c.

Dia, in *Mythology*, a goddeſs among the Romans, probably the ſame with Cybele.

Dia, in *Ancient Geography*, a town of Scythia, before Phaſis, near the Cimmerian Boſphorus.—Alſo, an iſland of the Mediterranean ſea, about three leagues from that of Crete, and rather a rock than an iſland; now called Standia. —Alſo, a town of Theſſaly, founded by Eacus, according to Steph. Byz.—Alſo, a town of Thrace, near mount Athos. —Alſo, a town of Eubœa, on the north ſide of the iſland, oppoſite to Theſſaly: it was alſo called Athenæ Diades, and is ſaid to have been founded by Dias, an Athenian, who called it after his own name, and that of his native city, Athens, Diades. The inhabitants of Dia peopled the city of Canæ, in Æolis.—Alſo, a town of the Peloponneſus, near the promontory *Scylleon*.—Alſo, a town of Luſitania, near the ocean.—Alſo, a town of Italy, near the Alps. Steph. Byz. ſays that ſeveral iſlands bore this name.

DIABATA, Diabeta, or Diabete, an iſland of the Mediterranean ſea, near that of Sardinia.

DIABATHRA, in *Antiquity*, a kind of ſhoe worn by the Grecian women. Pitiſc. Lex. Ant. in voc.

DIABE, in *Ichthyology*, the name of a prickly ſea-fiſh of the orbis, or globe-fiſh kind, and in all things reſembling the hiſtrix, or porcupine fiſh, except that its ſpines or prickles are all fixed into its ſkin by three inſertions. See Diodon.

DIABETÆ, in *Ancient Geography*, iſlands of the Mediterranean ſea, in the vicinity of that of Rhodes. Pliny ſays that there were four iſlands of this name.

DIABETES, in *Medicine*, a diſeaſe characteriſed principally by a profuſe excretion of urine.

The term diabetes is derived from διαβαινω, *tranſeo, I paſs through*, becauſe not only the fluid ingeſta, but ſome of the ſolid, paſs off by the urine.

Various other names have been given to this diſeaſe by the old writers. Thus, it has been called *dipſacus*, and *morbus ſitibundus*, from the great thirſt which accompanies it; *cachexia urinaria*, from the conſtitutional failure which enſues; alſo *fluxus urinæ*, *diarrhœa ad urinas*, *diarrhœa ad matulam*, &c.

The etymology of the word may admit of every immoderate diſcharge of urine being called diabetes; but its application is confined by phyſicians to an aſſemblage of ſymptoms, of which the increaſed flow of urine is the moſt obvious, at leaſt, in the commencement. The other diagnoſtic ſymptoms are, a great thirſt; and an unuſual craving for food; a dry, ſhrinking, and parched ſkin; a waſting of the fleſh and ſtrength; and particularly a ſweetneſs, or ſaccharine quality of the urine. In ſome caſes, indeed, this quality, without any increaſe of quantity, is the principal characteriſtic of the diſeaſe.

This diſeaſe commonly comes on ſlowly, and almoſt imperceptibly, without any previous diſorder. It often ariſes to a conſiderable degree, and ſubſiſts long, without being accompanied with evident diſorder in any particular part of the ſyſtem. There is, indeed, ſome difficulty in aſcertaining the firſt and earlieſt ſymptoms of the diſeaſe, or that ſtate of it in which the ſweetneſs and increaſe of the urine take place; as the diſcharge of the urine is generally conſidered by the patients as the neceſſary effect of the thirſt, and quantity of drink; it is thus for a long time often overlooked. But when the hectic fever, and waſting appear, the diſeaſe is then generally detected, and the hiſtory of it from that period has been accurately detailed.

Dr. Rollo affirms, that it can ſcarcely be doubted, that a previous affection of the ſtomach takes place before the period, or at the time when the peculiar character of the diſeaſe, by the production of ſaccharine matter, is formed, and ſenſibly ſhewn in the urine. In his firſt caſe, the bulimia canina exiſted, at leaſt, ſix months before the hectical ſtate of diabetes appeared, and ſome time before the increaſe in the diſcharge of urine; and morbid affections of the ſtomach are ſaid to have preceded the detection of the diabetic diſeaſe, in the caſes communicated. But this does not appear to have been always obſerved; and ſuch ſtatements of facts muſt be received with caution, where a particular hypotheſis is to be aided by their eſtabliſhment.

The moſt remarkable ſymptoms of diabetes, when completely formed, are voraciouſneſs of appetite, or a frequent craving for food, which is not followed by the feel of entire ſatiation; a parched mouth, with conſtant ſpitting of a thick viſcid phlegm, of a mawkiſh, ſweetiſh, or bitteriſh taſte; intenſe thirſt; a whitiſh tongue, with red bright ſides; red and ſwelled gums, with the teeth feeling as on edge from acids, and looſe in their ſockets; head-ach; a dry hot ſkin, with fluſhing of the face; a pulſe ranging from 80 to 90, but moſt generally about 84 or 86; an increaſe of clear urine, of a light ſtraw colour, having a ſweetiſh taſte reſembling ſugar, or rather honey and water; an uneaſineſs of the ſtomach and kidneys; a waſting of fleſh; a wearineſs and diſinclination to motion or exertion, with the feeling of weakneſs; an excoriation, with foreneſs of the glans, penis, and prepuce, which is ſometimes ſwelled, and often in the contracted ſtate of phymoſis; and the venereal appetite is altogether loſt. In females there is a peculiar uneaſineſs about the meatus urinarius. Theſe ſymptoms continuing, the patient becomes ſo enfeebled as to be confined to bed; an unremitting febrile ſtate and ſlight delirium take place, ſometimes with a removal of the peculiar character of diabetes.

In ſome inſtances the progreſs is ſlow, the ſymptoms remaining ſtationary, and even ſometimes becoming ſo ſlight as to induce the patient to ſuppoſe himſelf nearly in health. This ſtate, however, ſeems to have depended upon the accidental forbearance of thoſe things which aggravate the complaint. Deviations in diet and regimen; and mental emotions, eſpecially grief, anxiety, and vexation, generally increaſe the ſymptoms.

The appearance of the urine in different inſtances, and even at different periods of the ſame caſe, varies conſiderably; nay, it varies at different parts of the ſame day, according to the quantity and quality of the food, the length of time after eating, and the ſtate of the ſtomach at the time with regard to activity, which in the more chronic

degrees of the diſeaſe is variable, as to voraciouſneſs and craving, while in the acute it is more ſteady. In general the urine is not only copious, but of an odorous ſmell, tranſparent, of a light ſtraw colour, of a ſweetiſh taſte, and yielding, by evaporation, a ſaccharine matter, reſembling treacle or molaſſes. Sometimes, however, it ſcarcely exceeds in quantity the ordinary diſcharge of health; but in quality, has the diabetic character, of yielding the ſaccharine extract on evaporation; which, like all ſweet and ſaccharine ſubſtances, is capable of undergoing the vinous and acetous fermentations, and has every other quality of vegetable ſugars. The quantity of urine diſcharged is generally, however, greater than the quantity of liquid taken. Dr. Home, ſpeaking of one of his patients, ſays, "Arthur paſſed from 12 to 15 pints of urine during 24 hours. When he drank 10 pints, he paſſed 12; when he drank 12 pints, he paſſed 14 or 15; ſo that his urine exceeded his drink generally by two pints." His other patient, Murray, paſſed an exceſs of urine over his drink of 7 or 8 pints in the 24 hours: "when he drank 4, he paſſed 12 pints a day; when he drank 3, he paſſed 10 pints." The urine itſelf, in ſeveral caſes, has exceeded the whole ingeſta, ſolid and liquid; and in general there is a daily diminution of weight, ſo that the urine, together with the other diſcharges, generally exceeds the quantity of ingeſta. This loſs of weight was aſcertained in one or two caſes, publiſhed by Dr. Rollo, by weighing the patieut daily. And Dr. Home obſerves, with reſpect to his patient, Murray, that his ſolid food amounted nearly to the exceſs of his urine above his drink. But immenſe diſcharges of urine are mentioned by ſome authors; as in the caſe of the girl deſcribed by Cardanus, where 36 pints were paſſed each day, when her body weighed only 250 pounds, and her meat and drink only 7 pounds; and as in that of a woman mentioned by Shenckius, where the urine paſſed in a few days was more than the weight of her own body. But there is ſo much room for deception in ſuch inquiries, that theſe ſtatements muſt be received with caution.

The urine varies in other reſpects occaſionally. In ſome inſtances a whitiſh fluid, reſembling the chyle itſelf, is ſaid to have paſſed off from the kidnies. In other inſtances, the urine is ſaid to be inodorous and deſtitute of the ſaccharine quality; hence, writers have thought it neceſſary to mark this diſtinction by peculiar terms; this form of the diſeaſe being denominated diabetes *inſipidus*; the former D. *mellitus*, from the honey-like flavour of the urine. A reſpectable teacher in London, conſidering theſe two forms of the diſeaſe as altogether different in their nature, has propoſed to deſignate them by different generic titles, and to call the former *polyuria debilitans*, and the latter *melituria tabifica*, which ſufficiently expreſs the nature and tendency of the two diſorders. The diabetes, with clear inſipid urine, is a more rare occurrence. Dr. Cullen, who had ſeen twenty caſes of diabetes, had met with only one, in which the urine was not ſweet. He doubts, indeed, whether a caſe of idiopathic diabetes ever occurs, in which the urine is perfectly free from the ſaccharine matter.

While under the diabetes mellitus, the conſtitution may be attacked with other diſeaſes, which ſeem to be commonly of an inflammatory nature, and may prove fatal; indeed, the diabetic diatheſis appears to render the body very ſuſceptible of inflammation. It is curious, however, that the diabetes is ſometimes ſuſpended by the attack of another diſeaſe. We recollect to have heard Dr. Gregory, profeſſor of medicine at Edinburgh, mention two inſtances of this ſort which occurred in his practice; in one all the diabetic ſymptoms were ſuſpended during an attack of pneumonia, which ſupervened; and in the other during that of an inflammatory ſore throat.

The diabetes is mentioned in the writings of phyſicians of almoſt all ages. For if it has not been noted by Hippocrates or Proſper Alpinus, it has occupied the attention of Theophilus, Actuarius, Aretæus, Aetius, Paulus Ægineta, Avicenna, Galen, &c. Aretæus has given a long and clear hiſtory of the diſeaſe, and pointed out the profuſe diſcharge of urine, the emaciation and debility, the inextinguiſhable thirſt, yet the drink not equalling the urine in quantity. the parched ſkin, &c. all belonging to true diabetes. Galen ſays that he had ſeen but two caſes of diabetes, in which there was a conſtant thirſt, and diſcharge of liquids, unchanged in their quality; and he compares this diſeaſe of the kidnies to a lientery. But as he deſcribes many caſes of bulimous appetite, and great thirſt, it is probable that he had ſeen a greater number, in which the urinous affection had been overlooked.

It is ſingular, however, that the peculiar condition of the urine was unnoticed, as characteriſtic of the diſeaſe, till our countryman, Dr. Willis, pointed out its ſaccharine taſte; neither the ancients nor the moderns, in the other countries of Europe, had obſerved it, till they were directed to it by the Engliſh; hence the diabetes mellitus is called by Sauvages D. *anglicus*. The urine had been taſted, however, long before the time of Willis. For Trincavella deſcribes a caſe in which a julepum roſaceum was adminiſtered; and he affirms that the urine had the ſame colour and ſmell as the julep; and that ſome of the attendants who choſe to taſte it, ſaid that there was no change in the flavour. (De Rat. Curand. Partic. &c. lib. x. cap. 11.) And Hercules Saxonia mentions one ſpecies of diabetes, which he defines, "Legitima diabetes, eſt excretio rei potulentæ prorſus non mutatæ in odore; colore, et *ſapore*, per vias lotii." But like his friend Trincavella, he attributed the ſweet ſmell, colour, and taſte of the urine, to the ſweetened ptiſan which the patient had drunk. The ſaccharine beverage and diet of the eaſtern countries, Dr. Girdleſtone obſerves, will perhaps account for the ancient writers omitting to notice the honey-like taſte of the urine of diabetic patients. And as it was generally the practice of the French and Italian phyſicians to preſcribe, in moſt diſeaſes, ptiſans ſweetened with honies or ſyrups, it is not to be wondered at, that Willis was the firſt phyſician who poſitively noticed the honey-like taſte of the urine in true diabetes, as ariſing from a change which the drink had undergone. It may be remarked that that accurate obſerver of diſeaſes, Sydenham, has taken no notice whatever of the ſweetneſs of the urine in diabetes, notwithſtanding it had previouſly been pointed out by Willis.

The quantity of ſaccharine matter in the urine is, in ſome caſes, very conſiderable, and it is combined with a quantity of animal extractive matter. In the inſtances related by Dr. Home, the urine was evaporated by Dr. Black; Arthur's urine afforded an ounce and a half of a brown ſaccharine matter from each pound; Murray's, treated in the ſame way, gave but one ounce for each pound of a ſubſtance reſembling coarſe brown ſugar. So that Arthur paſſed twenty ounces and a half of this matter in twenty-four hours, when he made fifteen pints of urine. Dr. Home obſerves that this is a wonderful proportion of ſugar to the fluid; ſince a pound of aſs's milk affords only half an ounce of ſugar; and a pound of cow's milk, only half that quantity. The quantity of ſugar detected in the urine of captain Meredith, whoſe caſe is related by Dr. Rollo, was calculated at twenty-nine ounces in the twenty-four hours.

This ſugar-making proceſs, then, conſtitutes the eſſential part of the diſeaſe; it has been the ſubject of much enquiry;

quiry; and many hypotheſes have been reſorted to, to explain the nature of the proceſs, and to determine in what part of the ſyſtem, or by what organs, it is carried on. Dr. Mead conſidered diabetes as "akin to jaundice," and affirms that ſteatomatous tumors were always found in the liver; and "as to the ſweetneſs of the urine, this is all bilious, for the water of the bile ſeparated from its ſalt is ſweet." (Treatiſe on Poiſons, Eſſay 1ſt.) But in Dr. Home's patients, and others, no diſeaſe of the liver has been diſcovered on diſſection; and a better chemiſtry has refuted the notion that there is ſugar in the bile. Some authors conſider diabetes as a local diſeaſe of the kidneys, which not only pour out the increaſed quantity of urine, but by a morbid change in the action of the ſecretory veſſels, elaborate the ſaccharine matter too. Since the glands of the mammæ, they ſay, can ſecrete ſugar, why may not the kidneys? The analogy, however, is not correct. For the mammæ are formed by nature for the ſecretion of a ſaccharine fluid, the kidneys are not; we might therefore as well expect the kidneys to ſecrete bile, as to produce ſugar. Dr. Home has the merit of firſt ſuggeſting a theory, which, although exceedingly imperfect, approximates, perhaps, nearer to a rational and probable view of the ſubject than any other that has been conceived. Some had attributed it to ſpaſms of the ſecreting veſſels, in the kidneys, but he objects to this notion, becauſe antiſpaſmodics do not alleviate the ſymptoms, and becauſe ſpaſm will not account for the ſaccharine, aceſcent, and fermentable urine. In hyſteria the urine has none of the diabetic qualities. Others had attributed the diſeaſe to the perſpiration being diminiſhed, or the inhalation increaſed, as they can account for the quantity of urine ſo much ſurpaſſing the drink in no other way. But he juſtly objects, that this will not account for the particular qualities of the urine; that diaphoretics are not attended with any good effects in diabetes; and that in his two patients perſpiration and urine were increaſed at the ſame time.

"Were I to give a theory," ſays Dr. Home, "to explain the nature and ſymptoms of this wonderful diſeaſe, I would ſay, that it ariſes from a defect of the animal or aſſimilatory proceſs, by which the aliment is converted into the nature of our body. I have long looked on the exceſs or defect of this proceſs as the ſource of many diſorders. All putrid diſeaſes, the ſcurvy, &c. ſeem to be owing to its exceſs; acidity of the ſtomach, &c. to its defect. Among the latter diſeaſes diabetes may be arranged. For, 1. The remote cauſes ſhew it. It ariſes from what debilitates the body, as moiſture, preceding diſeaſes, great evacuations, &c. by which it becomes incapable to aſſimilate the food. So Sydenham thought, "Aſſimulandis ſuccis protinus impar eſt." 2. The white chylous matter, which is often ſecreted with the urine, ſhews, that the vegetable part of the chyle is not aſſimilated. The dilatation of the urinary excretories cannot, alone, account for this, as the ſerous part of the fluids would then eſcape too, which does not happen. 3. Sugar is found in diabetic urine. Sweet chyle is the firſt product of the ſtomachic and inteſtinal digeſtion; as chyle, in the thoracic duct, and milk, which is a ſpeedy ſecretion of it, contain much ſaccharine matter. This is changed, in ſome hours, by the animal proceſs, into an ammoniacal ſalt, which is that found in all the excretions. But the ſaccharine ſalt, ſtill remaining in the urine, which is the moſt perfectly animalized fluid, ſhews that there is great defect in the animal proceſs. 4. Urine being of a ſeptic nature, runs faſt into putreſcency. But the diabetic urine turns acidulous, and with, and often without yeaſt, undergoes the vinous fermentation. Theſe peculiarities ſhew its vegetable nature; as vegetable juices alone are capable of the vinous and acetous fermentations. Theſe arguments appear more convincing than any of the former. But it may be objected to them, 1. That animal food ſhould cure it, which it did not; 2. That ſeptics, which brought on putrid eructations, made no change; 3. That the proportion of ſaccharine matter is much greater in their urine, than in milk. But milk has not, perhaps, the whole ſaccharine ſalts of the chyle." (Clinical Experiments, p. 318, *et ſeq.*)

Dr. Cullen adopted a ſimilar opinion reſpecting the nature of diabetes, and believed that the proximate cauſe of the diſeaſe "is ſome fault in the aſſimilatory powers, or in thoſe employed in converting alimentary matter into the proper animal fluids" §1512 Firſt Lines. But he candidly acknowledged, that it was a theory embarraſſed with ſome difficulties which he could not very well remove.

Dr. Rollo has more recently taken up this theory, and attempted to reduce it to a more definite form. "The immediate cauſe of the diabetes mellitus," he ſays, "is a morbid condition of the ſtomach, forming or evolving from vegetable ſubſtances ſaccharine matter, which is quickly ſeparated, as a foreign body, by the kidneys. But to be more particular; we allege that this diſeaſe conſiſts in an increaſed morbid action of the ſtomach, with too great a ſecretion and an alteration in the quality of the gaſtric fluid, producing ſaccharine matter, by a decompoſition of the vegetable ſubſtances, taken in with the food, which remains unchanged." This hypotheſis is ſupported by the following arguments. 1ſt. That a ſtomach-affection generally precedes the urinary characteriſtic ſymptoms of the diſeaſe. 2dly. That a ſtomach-affection always accompanies the diſeaſe, and is materially different from that which is ſympathetic of primary affection in the kidneys. 3dly. That a diet of animal food, with an entire abſtinence from vegetable or other matters, capable of forming ſugar in the ſtomach, removes ſpeedily the general ſymptoms, the ſaccharine matter, the increaſe of urine, and its unnatural qualities: and, 4thly. That diſſection has ſhewn no morbid condition of the kidneys, but what may be referred to a continuance of increaſed action, from the application of a ſimple ſtimulus, augmenting merely the capacity of the veſſels. (Rollo on Diabetes, 2d edit. p. 436.)

It has been objected to this theory, that if the ſaccharine matter is formed by the ſtomach, it ſhould be detected in the blood, in its way to the kidneys; but that this has not been done. But to this it is replied, that the taſte is a very inaccurate teſt of the exiſtence of any matter in ſuch combination; that Dr. Dobſon affirmed that ſaccharine matter did exiſt in the ſerum of the blood, in a caſe treated by him, (Med. Obſ. and Inquir. vol. v.) that the ſerum in one or two caſes has been obſerved to be of a whey-like colour; and that certain matters, as nitre, turpentine, &c. may paſs by the kidneys, without being detected in the blood. Theſe ſtatements, however, can hardly be conſidered as ſatisfactory refutations of the objection, or as removing the doubt which hangs over the ſubject.

No light is thrown upon the nature of diabetes by a conſideration of its exciting cauſes; for the moſt various and even oppoſite cauſes have been aſſigned for it, in the various inſtances that are on record. The diſeaſe has been obſerved to follow acute diſeaſes, eſpecially fevers; Sydenham remarked that it followed intermittents, eſpecially if much venæſection had been uſed. Acrid purgatives are alſo ſaid to have given riſe to it by Sydenham; and Dr. Home affirms that he knew the chylous ſpecies brought on by too frequent doſes of jalap and calomel. The exceſſive uſe of cold watery liquors appears to have occaſioned diabetes in ſome caſes; as drinking largely of particular mineral waters; of weak acid

Rheniſh

Rheniſh wines; and more eſpecially of liquors impregnated with a diuretic quality. Cold-bathing, and expoſure to cold and moiſture, under various circumſtances, have likewiſe been ſaid to excite the diſeaſe. In ſeveral caſes, collected by Dr. Rollo, there was an obvious hereditary diſpoſition to the diſeaſe, which attacked individuals of the ſame, as well as of diff-rent generations, in the ſame family.

Diſſection has not contributed in any degree to elucidate the nature of diabetes. The liver has been frequently found in a perfectly ſound ſtate, contrary to the obſervation of Dr. Mead; and often no morbid change could be detected in any organ of the body. The kidneys have generally been found enlarged, eſpecially the tubular uriniferous portion, and ſofter than natural; but this is as probably the effect of the quantity of liquid conſtantly ſtraining through it, as the cauſe of the increaſed ſecretion. In ſome caſes even the kidneys have been found in a perfectly natural condition. (See the diſſections in Dr. Rollo's book, and in Dr. Home's; and two others related by profeſſor Rutherford, in the third number of the Edinburgh Medical and Surgical Journal, 1805. Another by Dr. Baillie, Tranſlations of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. ii.)

In this ſtate of uncertainty in regard to the ſeat and nature of the *diſeaſe*, the *cure* of diabetes cannot be directed with any certainty of ſucceſs, or upon the rational principle of removing the proximate cauſe. All thoſe who have ſeen the diſeaſe, agree in pronouncing it difficult of cure, eſpecially if the patient is old, if it aroſe from habitual drinking, or if it has been of long ſtanding; and various medicines have been reſorted to, according to the various opinions of the practitioners, or as the failure of preceding remedies ſuggeſted a change. Many of theſe have been ſaid to effect a cure in individual inſtances; but in the hands of different practitioners, they have ſo often failed reſpectively, that their efficacy muſt be doubted.

Some have ſuggeſted, that, by reſtoring the function of perſpiration, the unuſual determination to the kidneys would be diminiſhed; and have hence recommended ſudorific medicines, as the warm bath, warm clothing, friction with oil, &c. In one inſtance, the warm bath was ſaid to have cured the diſeaſe, under the direction of a Mr. Werner. (See London Medical Journal for 1790.) And Dr. Mac Cormick, of Antrim, mentions two caſes of diabetes, which were cured by the continued uſe of large doſes of Dover's powder at bed-time. (See Duncan's Medical Commentaries for 1783.) But in many other caſes, ſuch medicines have failed altogether to give relief. In thoſe treated by Dr. Home, although ſweating was produced, the excretion by the kidneys was not diminiſhed. Antiſpaſmodics have had no effect on the diſeaſe, nor have ſtimulants, ſuppoſed to act upon the lax kidneys, as ſuggeſted by Dr. Briſbane, been of any uſe. He recommended, upon this principle, the tincture of cantharides, a medicine which has not been obſerved to have any efficacy in this complaint. Aſtringents have been tried, as in other increaſed evacuations; ſuch as alum, and alum-whey, ſo ſtrongly recommended by Dr. Mead, upon theoretical principles; alſo gum kino, and catechu, in conſiderable doſes, but generally without ſucceſs. Dr. Fothergill's patient is ſaid to have recovered, after taking alum-whey, lime-water, and ſudorifics, calomel and rhubarb, and having a bliſter applied over the ſacrum. (Med. Obſervat. and Inquiries vol. iii.) And Morton cured a patient by a milk diet, an aſtringent julep, and electuaries of bole, and gum tragacanth. Tonic and corroborant medicines have alſo been employed, to reſtore the ſtrength and health of the conſtitution at large, and of the digeſtive organs in particular. Peruvian bark, bitters, chalybeates, the cold bath, &c., have been among the remedies of this claſs, that have been uſed; and theſe, like the others, in a few individual inſtances, have been ſaid to remove the ſymptoms; but more frequently, as in Dr. Home's caſes, and others, they have failed. In one of Dr. Ferriar's patients, cinchona and ſulphuric acid contributed to reduce the urine from 10*lb.* daily, to its natural ſtate. And the ſame author affirms, that he had lately cured three caſes of confirmed diabetes, by a combination of cinchona with uva urſi and opium; the ſucceſs of which had been ſo great as to prevent him from trying Dr. Rollo's plan. (Ferriar's Eſſay on Digitalis. See alſo his Medical Hiſtories and Reflections, vol. i.)

It is obvious, that all the medicines which have been employed for the cure of diabetes have been, in a great majority of caſes, altogether unſucceſsful; nor can all the caſes be conſidered as abſolutely cured, which have been recorded as ſuch. For it is certain that in many inſtances, where the ſymptoms of diabetes, eſpecially the morbid quantity of urine have been ſuſpended, they have nevertheleſs ſpeedily returned, where the remedies were omitted, and ultimately proved fatal. The moſt ſucceſsful plan of treatment that has yet been deviſed, we have now to mention.

Upon the ſuppoſition that the diſeaſe conſiſts eſſentially in a defect of the power of aſſimilation, whence the unanimalized, chylous juices, were ſuffered to paſs off in their crude ſtate; it was long ago ſuggeſted by the ſagacity of Sydenham, that the diabetic patient ought to eat meats of eaſy digeſtion, ſuch as veal, mutton, and the like, and to abſtain from all vegetables and fruit whatever. (See his Epiſtle to Dr. Brady.) Dr. Home again ſuggeſted the ſame expedient, and mentions its failure as a reaſon for doubting the correctneſs of the theory. But the ſuggeſtion had never been put to the teſt of ſevere experiment, and was therefore almoſt forgotten, till Dr. Rollo had the merit of calling the attention of the profeſſion to the ſubject.

As we are ignorant of the nature of the action of the chylopoetic or aſſimilatory organs, in producing the ſaccharine matter, the only practicable mode of preventing its formation, is the abſtraction of the pabulum of this matter, *i. e.* of all vegetable ſubſtances from the diet. And while we thus remove the means of forming ſaccharine matter, it is not unlikely that we may remove the morbid action, in the courſe of time, upon which its formation depends. This was the mode in which Dr. Rollo reaſoned. Animal food, confinement, with an entire abſtinence from every kind of vegetable ſubſtance, afforded the general means, which might perhaps be aided by the uſe of ſuch medicines as ſeem to be moſt remote from any thing like a vegetable, aceſcent, or ſaccharine quality; as ſulphur, ſulphurated potaſs, or ammonia, alkalies alone, and calcareous and teſtaceous ſubſtances. The ſucceſs of the excluſively animal diet was ſpeedy and great in the caſe of captain Meredith, related by Dr. Rollo; and in his ſecond caſe decided benefit accrued from its uſe, while it was perſevered in. The plan with which captain M. commenced was the following:

Breakfaſt.—One and a half pint of milk, and half a pint of lime water, mixed together, and bread and butter.

Noon.—Plain black puddings, made of blood and ſuet only.

Dinner.—Game or old meats, which have been long kept, and as far as the ſtomach may bear, fat and rancid old meats, as pork. To eat in moderation.

Supper.—The ſame as breakfaſt.

Secondly. A drachm of kali ſulphuratum, to be diſſolved in four quarts of water, which has been boiled, and to be uſed for daily drink. No other article, either eatable or drinkable, to be uſed than what has been ſtated.

In three days the diabetic ſymptoms were obviouſly diminiſhed. Every portion of vegetable matter was then omitted, even the bread. By perſevering in this regimen the ſymptoms were entirely removed. The urine returned to its natural quantity and quality; the patient regained his ſtrength, and recovered much of his fleſh, and went on actual ſervice. In the courſe of his cure, he one day ate an apple, which increaſed the urine by nearly a quart, and brought back its ſaccharine quality. The diſeaſe, in this caſe, had been but of ſeven months' duration, when the plan of cure was begun.

In Dr. Rollo's ſecond caſe, the diſeaſe was of at leaſt three years ſtanding; the animal diet produced a conſiderable alleviation of the ſymptoms, during the ſhort time that it was perſevered in; but, having relinquiſhed it, the patient ſuffered a return of all the ſymptoms, and died.

From the facts, which Dr. Rollo has ſtated from his own obſervation, and the caſes communicated to him by other practitioners, it cannot be doubted that the animal diet has a great influence on the ſymptoms of diabetes, and has contributed more directly and effectually to its alleviation, than any meaſure hitherto adopted; and that where the plan is proſecuted with great ſteadineſs and perſeverance in recent caſes, a cure may probably be effected. It is to be lamented, however, that this mode of cure is ſo contrary to the inclinations of the ſick, that it is almoſt impoſſible to prevail upon them to perſevere in its uſe. The deſire for vegetable matters in ſome ſhape or other ſeems to be almoſt irreſiſtible. Though perfectly aware of the efficacy of the regimen, ſays Dr. Rollo, yet they commonly treſpaſs, concealing what they feel as a tranſgreſſion againſt themſelves. They expreſs a regret, that a medicine could not be diſcovered, however nauſeous, which would ſuperſede the neceſſity of any reſtriction in diet.

When, during the uſe of the animal diet, the urine has loſt its ſaccharine quality, and at the ſame time its quantity continues greater than natural, and it contains more of the animal extractive matter in a viſcid and tenacious form, the appetite remaining keen, it may be preſumed that the morbid condition (the increaſed action according to Dr. Rollo) of the digeſtive organs is not removed. The hepatized ammonia, opium, and antimony, may then be reſorted to, until the urine ſhews a more natural condition; namely, becomes moderate in quantity, and high-coloured, with ſome turbidneſs, and furniſhing on evaporation an offenſively ſmelling and ſaltiſh-taſted reſiduum, without tenacity; and the ſtomach at the ſame time loathes food, and the appetite is loſt. At this time the tongue and gums will be found to have loſt their florid colour, and to have become pallid.

When ſuch a ſtate occurs, exerciſe is to be enjoined, and a gradual return to the uſe of bread, and of thoſe vegetables and drinks which are the leaſt likely to furniſh ſaccharine matter, or to become acid in the ſtomach, with the occaſional uſe of bitters, &c. Should this period of the diſeaſe be overlooked, and the confinement and animal food rigidly perſevered in, ſcurvy, or ſomething akin to it, might be produced. The vegetable ſubſtances, which have appeared to be the ſafeſt, in the change from the animal diet, are broccoli, ſpinage, cauliflower, cabbage, and lettuce. Theſe do not ſeem to furniſh ſugar, when prudently uſed, in the diabetic ſtomach, after a proper adoption of the animal diet. But when theſe vegetables have been ſafely taken, a return to a very ſmall quantity of bread has reproduced the ſaccharine matter in the urine, and the general ſymptoms of diſtreſs, as thirſt, &c. The urine ſhould, at this period, be very frequently examined, and on any appearance of a return of the diabetic ſtate of it, the animal diet muſt be again ſtrictly renewed. A frequent examination of the urine at all times will afford the beſt teſt of the ſtate of the diſorder, and of the nature of the treatment which may be required. Rollo.

It is to be remarked, however, that in ſome caſes, the animal diet has ſucceeded in changing the condition of the urine, whilſt the emaciation, and the eſſential conſtitutional condition have remained. And it is the obſervation of a very intelligent phyſician, that he never ſaw a confirmed caſe of diabetes, "wherein there was not ſome conſiderable diſorder of the conſtitution, or a defect of ſome organ eſſential to life." (Willan on Diſeaſes in London, p. 186.)

The preceding obſervations apply to the common form of the diſeaſe, the diabetes *mellitus*. In the D. *inſipidus*, where the diſeaſe conſiſts merely in a profuſe ſecretion of the natural urine, from a morbidly increaſed action of the ſecreting veſſels of the kidneys, the prognoſis is more favourable. The latter form of the diſorder appears to have been occaſionally produced by the ſtimulus of a calculus in the kidney; at other times without any obvious cauſe of ſtimulation in that organ. The indications in the D. *inſipidus*, will be, to leſſen the determination of blood to the kidneys, by increaſing the perſpiration by diaphoretic medicine, warm-bath, &c.; to avoid thoſe articles of diet and drink, which have a particular diſpoſition to excite the action of the kidneys, as much warm liquor, ſuch as tea, punch, &c.; and to ſtrengthen the ſyſtem at large by the various tonic medicines, bark, ſteel, bitters, &c. The aſtringent medicines are particularly indicated in this form of the diſeaſe, where the diminution of a natural excretion is alone to be attempted. Hence the alum or alum-whey, gum kino, bark, and ſulphuric acid, uva urſi, &c., may be adminiſtered with more rational hopes of ſucceſs, than in the D. *mellitus*. Drains from the vicinity of the region of the kidneys, as bliſters, or iſſues in the loins, may be alſo tried, as means of diverting the courſe of the fluids from the kidneys.

Diabetes, or *Exceſſive Staling*, in *Farriery*, a diſeaſe of horſes which, at its commencement, admits of an eaſy cure; but which often proves very obſtinate, and even incurable. At firſt the complaint conſiſts merely in an increaſed ſecretion of urine, which is generally tranſparent and colourleſs, like water; but at length the horſe becomes feveriſh, and ſuffers much from thirſt; his appetite is diminiſhed, and his pulſe is quickened; he is generally hide-bound, and gradually loſes fleſh and ſtrength. Some have recommended lime-water in this diſeaſe; others have had recourſe to diaphoretic medicines, in order to promote perſpiration. Bark and other tonics have been alſo preſcribed as uſeful remedies. Mr. White, in his "Compendium of the Veterinary Art," informs us, that, in recent caſes, he adminiſtered with ſucceſs the following ball; *viz.* opium, 1 dram, powdered ginger, 2 dr., and yellow Peruvian bark, ½ oz., formed into a ball with ſyrup, for one doſe. If this remedy ſhould fail, he recommends one of the following formulæ: 1. Emetic tartar, 2 dr., opium, 1 dr. made into a ball for one doſe: 2. Salt of hartſhorn, 2 dr., opium, ½ dr., powdered ginger, 1 dr., liquorice powder, 3 dr. formed into a ball for one doſe: 3. Salt of ſteel, ½ oz., myrrh, 2 dr., ginger, 1 dr. made into a ball for one doſe: 4. Powdered Columbo-root, 3 dr., caſcarilla, 2 dr., ſalt of ſteel, 2½ dr., prepared kali, 1½ dr., and tincture of opium, ½ oz.; the ſeveral ingredients to be mixed with ſtrong beer, or porter, and given as a drink at once. He obſerves, that the horſe's diet ſhould be nutritious, and eaſy of digeſtion; and that he ſhould be allowed to drink ſmall quantities of weak lime-water; or, if he refuſe this, common water, frequently. Mr. Taplin, in his "Stable Directory," recommends the following drink: "Take jeſuit's bark, 4 oz., biſtort and tormentil roots, of each 2 oz.; boil them in two

gallons of lime-water to the conſumption of one-half, and give a pint of the liquor three times a day. As this diſorder generally proceeds from too violent exerciſe, overſtraining, &c. repeated bleedings in ſmall quantities are abſolutely neceſſary, till the mouths of the veſſels cloſe up.

DIABETES, in *Hydraulics*, is applied to a ſyphon, the two legs or branches whereof are incloſed in one another; as in the glaſs deſcribed by Hero, which runs itſelf quite empty, without being inverted, as ſoon as the water is arrived at the height of the upper branch of the ſyphon.

DIABLINDI, in *Ancient Geography*, a people of Gaul, ſituated between the Redones on the weſt, and the Aulerci on the eaſt. Their capital was Nœodunum.

DIABOLUS MARINUS. See *Sea*-DEVIL.

DIABOTANUM, from *δια* and *βοτανη*, *herb*, in *Pharmacy* and *Chirurgery*, denotes a plaſter of herbs, wherewith wens, &c. are reſolved and diſcuſſed. The diabotanum is ſovereign for the hydatides.

DIABROSIS, in *Medicine*, a term uſed by the older writers to denote a rupture of the veſſels, in conſequence of the corroſion of acrid humours. It is derived from *δια* and *ϵρωσις*, *eroſion*. Thus an hæmoptyſis, or diſcharge of blood from the lungs, was ſaid to take place in ſeveral ways, as by a violent rupture of the veſſels, by a dilatation of their orifices, and by a diabroſis, when the veſſels were corroded by the acrimony of the fluids. Vogel has conſtituted a genus of diſeaſe, in his noſology, under the title of diabroſis, and defines it, "an eroſion of the ſkin by an acrid matter, either internal or external." See his Genera Morbor. claſs x. Ord. 6.

DIACARYON, or DIANUCUM, in *Pharmacy*. See DIANUCUM.

The word is formed from *δια*, and *καρυα*, walnut.

Galen is ſaid to have prepared his diacaryon with the juice of walnuts, mixed with as much honey as ſufficed to render it an agreeable compoſition.

DIACAUSTIC CURVE, or *Curve by Refraction*. See *Cauſtic* CURVE.

DIACENTROS, from *δια*, *through*, and *κεντρον*, *centre*, in *Aſtronomy*, is uſed by Kepler to ſignify the ſhorteſt diameter of the elliptical orbit of any planet; probably becauſe it paſſed through the centre, and not through the focus, which diſtinguiſhes it from the longer diameter.

DIACHALASIS, from *διαχαλαω*, *to be relaxed*, in the *Medicinal Works of the Ancients*, a term uſed to expreſs a ſolution of continuity in the bones of the cranium at the ſutures; that is, when the bones recede from their mutual indentation; an accident that frequently happens from large wounds in the head.

DIACHALCYTES, in *Pharmacy*, the name of a plaſter. See EMPLASTRUM.

DIACHER, in *Geography*, a town in Perſia, in the province of Mazanderan; 24 miles S. W. of Zaeveh.

DIACHERSIS, in *Ancient Geography*, a town of Africa, in the Cyrenaica, where the Romans had a garriſon.

DIACHRISTA, from *δια* and *χριω*, *I anoint*, a name given by the ancient writers in medicine to certain compoſitions, whoſe uſe was to be applied to the fauces, uvula, palate, and tongue, for the abſterſion of phlegm.

DIACHYLON, in *Surgery*, a ſpecies of plaſter, now called litharge plaſter by the college of phyſicians. It is one of the moſt ſimple and emollient applications adapted for the reſolution of indurated ſwellings. See PLASTER, and LITHARGE.

DIACODIATE, in the older writers on *Medicine*, ſynonymous with narcotic, or opiate, from *δια* and *κωδια*, the *poppy-head*, or capſule. See Van Swieten.

DIACODIUM, in *Pharmacy*, the name of a ſyrup, the principal ingredient of which is the white poppy-head, and which poſſeſſes much of the anodyne property of this plant. The ſyrupus diacodion was made in the following way: Take of white poppy-heads and of the ſeeds, of each two ounces, of cubebs two ounces and a half; cut them into ſmall pieces, and boil them ſlowly with a pint and a half of water, till only ten ounces of liquor remain, adding towards the end of the coction an ounce and a half of liquorice root. Collect the liquor, by ſtrongly ſqueezing the ingredients through a coarſe cloth, and diſſolve therein ſixteen ounces of fine ſugar, or, as ſome adviſe, of brown ſugar-candy, and ſtrain and deſpumate the ſyrup in the uſual way.

A variety of the diacodium is made by adding a dram of ſaffron to the above quantity of the ſyrup.

The diacodium is a medicine of very conſiderable value, being a weak opiate, which appears to produce very little of the inconvenience which opium in ſubſtance occaſions. It is particularly uſeful in various diſeaſes of very young infants, and its pleaſant taſte is no ſmall additional advantage. To adults, its opiate properties are hardly powerful enough to ſuperſede the opium in ſubſtance or in tincture.

As the ſimple ſyrup of poppies appears to poſſeſs all the virtues of the diacodium, it is now very generally ſubſtituted to it, and the diacodium is now omitted in our pharmacopœias.

DIACODUS, in *Natural Hiſtory*, a name given by ſome to the diadochos, a kind of beryl or ſapphire, of which many fabulous things are aſſerted,

DIACOLOCYNTHUS, in *Pharmacy*, an electuary, in which colocynth is the principal ingredient. It is now diſuſed.

DIACOMMATIC, in *Muſic*, has ſometimes been uſed to expreſs the frequent temperaments of a whole comma major in the melody, which are neceſſary for enabling the different parts of a piece of muſic always to make perfect harmony with each other. See Dr. Callcott's Muſical Grammar, p. 136.

DIACONICON, SACRISTY, a place adjoining to the ancient churches, where the ſacred veſtments, with the veſſels, relics, and other ornaments of the altar were preſerved, and anſwering to our veſtry.

The word is Greek, formed from *διακονεω*, *I ſerve, I miniſter*, becauſe here was kept every thing belonging to divine ſervice. It was alſo called *ασπαστικον*, and in Latin ſalutatorium; becauſe it was here that the biſhop received and ſaluted ſtrangers. Sometimes, too, it was called *μηπατωριον*, or *μιπατωριον*, *menſa*, on account of the tables kept therein, for diſpoſing the ſacred ornaments on; or rather from *μηπατον*, a ſort of inn, or houſe, for the lodging of ſoldiers.

DIACONISSA, and DIACONATE. See DEACON, and DEACONRY.

DIACOPE, *Διακοπη*, from *δια* and *κοπτω*, *I cut off*, in *Grammar*, the ſame with what is otherwiſe called tmeſis.

DIACOPE, in *Surgery*, denotes a deep cut or wound; or the act of cutting off any part.

DIACOPENA, in *Ancient Geography*, a country placed by Strabo in Aſia Minor, between the rivers Halys and Iris, near the country which he calls *Pimoleſina*.

DIACOPTON, a city of Achaia Propria, about 60 furlongs diſtant from the gulf of Corinth; formerly called *Pellene*, or *Pellina*.

DIACOUSTICS, (from *δια*, *through*, and *ακουω*, *I hear*;)

tain. On theſe ſet off 56 toiſes, from C to G, and D to H, for the faces CG, DH, of the counter-guards. The flanks and tenailles are found or determined as in his firſt method.

The ditch before the ſaliant angles of the towers is ſix toiſes broad, and its counterſcarp is drawn to the extremities of the flanks of the counter-guards. The right line, which joins the ends of theſe flanks, determines the inſide of the tenailles.

The ditch before the counter-guards is 12 toiſes broad at the ſaliant angles, and its counterſcarp is drawn towards the oppoſite ſhoulders, in the ſame manner as in his firſt method.

The capital of the ravelin is 45 toiſes, and its faces, when produced, terminate on thoſe of the counter-guards, about 10 toiſes from the ſhoulders. Ten toiſes, however, are cut off from the faces of the ravelin, for the flanks which are parallel to its capital.

The ditch before the ravelin is 10 toiſes broad, the covert-way five, the ſemi-gorges of the places of arms 12 each, the faces 17 each, and the glacis is 20 toiſes broad.

The conſtruction of Mr. Vauban's third method, according to the plan of New Briſach, is applied to an octagon, of which the exterior ſide is equal to 180 toiſes, and is made inwards. The perpendicular to the exterior ſide is, as in his firſt method, equal to 30 toiſes. The faces of the counter-guards are each of them equal to 60 toiſes. The flanks are found by ſetting off 22 toiſes, in arcs deſcribed from the oppoſite ſhoulders, as centres, and with the diſtance between as radius. A right line drawn through the extremities of the flanks, parallel to the exterior ſide, to meet the capitals of the counter-guards, determines both the inſide of the tenailles, and the ſaliant angles of the tower-baſtion.

And if another right line be drawn parallel to this, at the diſtance of nine toiſes from it, the points, where it meets or interſects the capitals of the counter-guards, will be centres of the towers; from which points, if ſeven toiſes be ſet off each way for their demi-gorges, the poſitions of their flanks, which are perpendicular to the ſaid line, will be determined. For each of theſe flanks, five toiſes are ſet off outwards, and four from the ſaid line. And the line joining the inſide of the flanks at the end of four toiſes completes the towers.

The ditch is ſix toiſes broad before the ſaliant angles of the towers, and its counterſcarp meets the line joining theſe angles, within ten toiſes of the extremities of the flanks of the counter-guards.

The great ditch before the counter-guards is 15 toiſes broad, and its counterſcarp is parallel to the faces. The capital of the ravelin is 55 toiſes in length, and that of the redoubt within it, is equal to 23 toiſes. The faces of the ravelin are drawn towards thoſe of the counter-guards, within 15 toiſes from the ſhoulders, and thoſe of the redoubt are parallel to theſe. Twelve toiſes are cut off from each face of the ravelin, and ſix from each of the redoubts by the flanks, which are parallel to its capital. The ditch before the ravelin is twelve toiſes wide, and that before the redoubt is ſix. The covert-way and glacis are the ſame as in his ſecond method. The profiles alſo are nearly the ſame in both. This method, indeed, differs but little from his ſecond, except in two ſmall flanks, of about four toiſes each, which in this he makes in each curtain, that are not in the other. The parapets of his counter-guards, on both ſides of the ſaliant angles for the diſtance of about twenty feet, are raiſed four feet higher than the reſt, to prevent theſe works from being annoyed by ricochet-batteries.

In Mr. Vauban's firſt method of military conſtruction, it may not be amiſs to give a table of the principal parts thereof, for drawing the maſter-line by, as alſo an ichnographical one of the principal dimenſions of the body of the place, tenailles, ravelin, covert-way, traverſes, and places of arms, as publiſhed with his approbation (for he never publiſhed any thing himſelf reſpecting it.)

TABLE for the Conſtruction.

	Forts.						Little Fortification.				Mean.		Great.	
Side of Figure, or Polygon.	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendiculars.	10	11	12½	14	15	16	20	21	23	25	30	31	25	22
Faces of Baſtions.	22	25	28	30	33	35	40	42	45	47	50	53	55	60
Capitals of Ravelins.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

And the following is an ichnographical table of the thickneſſes, &c. of the works compoſing the body of the place, &c.

Toiſes.

Of the Body of the Place.
- Thickneſs of the rampart at its baſe - - - - - 11
- Thickneſs of the parapet at its baſe - - - - 3
- The breadth of the ditch - - 20

Toiſes.

Of the Tenaille.
- Its diſtance from the orillon of the baſtion - - - - 3
- Thickneſs of its rampart in the face and flank at the baſe - - 7
- Thickneſs of the rampart of its curtain at the baſe - - - 5
- Thickneſs of its parapet at the baſe - - - - 3

Thickneſs

is repreſented with a diadem, adorned with rays: though even after Conſtantine, when the diadem was become the uſual ornament of the Auguſti, it was not always given to the Cæſars. Indeed, we ſee it on ſome of the medals of Julian, while only Cæſar; though it is pretty certain, he did not wear it until he became Auguſtus. Du-Cange will not aſſert, that Conſtantine firſt took the diadem; but only, that he firſt made it into a kind of caſk, or cloſe crown, as is ſeen in ſome of his medals, and thoſe of his ſucceſſors.

DIADEM, in *Heraldry*, is applied to certain circles or rims, ſerving to bind or encloſe the crowns of ſovereign princes; and to bear the globe, and croſs, or the fleurs de-lis, for their creſt.

The crowns of ſovereigns differ in this, that ſome are bound with a greater, and ſome with a leſs, number of diadems.

Prelates likewiſe appear to have anciently worn a ſort of diadem; thus Baronius writes, that St. James the apoſtle wore a gold plate on his forehead, as a mark of his epiſcopal dignity.

In blazoning, the bandage about the heads of Moors, on ſhields, is ſometimes alſo called diadem. The term *diademed* is applied to the imperial eagle, the two heads of which are ſurrounded with an annulet or circle, which is a token of greater dignity than to be *crowned*, as the eagles of other princes are.

DIADES ATHENÆ, in *Ancient Geography*. See DIA.

DIADOCHUS, in *Natural Hiſtory*, the name given by the ancients to a gem, approaching to the nature of the beryl, or aqua-marina, probably a pale ſapphire; for they had no peculiar generical name for that gem, but called the beautiful deep coloured ones only ſky-blue beryls, berylli aeroides. The writers of the middle age have given ſtrange accounts of the magical virtues of this ſtone, ſuch as its calling up ſpirits, and many other the like things, on being thrown into water: they ſaid, however, that if it happened by any accident to touch a dead body it loſt all its virtue.

DIADOCOPOTIS, in *Ancient Geography*, a town of Aſia, in the Perſide. Steph. Byz.

DIADROME, from διὰ and δρόμος, *curſus*, is ſometimes uſed for the vibration, motion, or ſwing of a pendulum.

DIÆRESIS, in *Grammar*, is a figure whereby a diphthong is divided into two ſyllables: as aulæ into aulai, pictæ into pictai, aquæ into aquai.

DIÆRESIS is alſo uſed, in a general ſenſe, for any diviſion of one ſyllable into two: as in that verſe of Tibullus, "Stamina non ulli diſſoliinda deo," for diſſolvenda.

This is uſually noted by two points placed over a letter, to ſhew that it is to be ſounded by itſelf, and not joined with any other ſo as to make it a diphthong: thus *aëra*, by the points over the *e*, is diſtinguiſhed from *æra*.

It is alſo a kind of metaplaſm, or addition to a word, by dividing one ſyllable into two: as aulae, by a diæreſis, is a word of three ſyllables, inſtead of aulæ. See TMESIS.

DIÆRESIS, in *Surgery*, the operation of dividing and repairing parts, whoſe union and continuity were an obſtacle to the cure; or which were joined and conglutinated contrary to the order of nature.

The word, in its original Greek, διαιρεσις, ſignifies diviſion.

There are five ways of performing the diæreſis, *viz.* by cutting, pricking, tearing, drawing, and burning.

DIÆTETÆ, Διαιτηται, from διαιταω, *I arbitrate*, among the Athenians, were of two ſorts, the cleroti and dialacterii. The former were a kind of public arbitrators, choſen by lot, to determine all cauſes exceeding ten drachms within their own tribe. Their office was annual, at the expiration of which they were obliged to give up their accounts; and if it was proved, that they refuſed to give judgment, or to have been corrupted, they were puniſhed with infamy. Their ſentence, however, was not final, an appeal lying from it to the ſuperior courts.

The dialacterii, on the contrary, were private arbitrators, from whoſe ſentence there lay no appeal; and accordingly they always took an oath to adminiſter juſtice, without partiality, which the cleroti did not. Potter's Archæol. Græc. lib. i. cap. 22. tom. i. p. 122, ſeq.

DIAFERI, in *Geography*, a town of Perſia, in the province of Chorafan; 135 miles N. of Herat.

DIAGEBRES, in *Ancient Geography*, a people of the iſland of Sardinia, according to Strabo.

DIAGLAUCIUM, a name given by the old writers on *Medicine* to a ſort of collyrium, in which the juice of the glaucium, or yellow poppy, was a principal ingredient. It was uſed for beginning lippitudes and ophthalmies.

DIAGLYPHICE, from διαγλυφω, *I engrave*, the art of engraving, cutting, or otherwiſe working, hollow or concave figures, in metals; ſuch as ſeals, intaglios, matrices for coins or medals, &c. See SCULPTURE.

DIAGNOSIS, in *Medicine*, from διὰ and γινώσκω, *I know*, the diſtinction of the nature of one diſeaſe from that of another, reſembling it, by means of a collected view of the ſymptoms; whence

DIAGNOSTIC SYMPTOMS, are the leading ſymptoms, or thoſe which are moſt characteriſtic of any particular form or ſeat of diſeaſe. Thus cough, difficulty of breathing, pain in the cheſt, and fever, are the diagnoſtic ſymptoms of pleuriſy. If any one of theſe is abſent, the remaining three are not ſufficient to denote inflammation of the cheſt. From the various combinations and degrees of the ſymptoms of diſeaſe, it is obvious that the knowledge of diagnoſtics is one of the moſt important and difficult branches of the ſcience of medicine; and it is the poſſeſſion of this knowledge by which the judicious phyſician riſes ſo far ſuperior to the empiric.

DIAGONAL, in *Geometry*, a right line drawn acroſs a parallelogram, or other quadrilateral figure, from the vertex of one angle to that of another.

Such is the line P N (*Plate* VI. *Geometry*, *fig.* 75.) drawn from the angle P to N.

Some authors call it diameter, and others the diametral of the figure.

It is demonſtrated, 1. That every diagonal divides a parallelogram into two equal parts; for the oppoſite ſides, O P, N Q. and O N, P Q, being parallel (*fig.* 75.) and the alternate angles Q N P, O P N, and Q P N, P N O being reſpectively equal, and the ſide N P, common to the equiangular triangles O P N, P N Q, theſe triangles are equal. 2. Two diagonals drawn in any parallelogram, biſect each other, for the triangles O M P, N M Q, being equiangular, and having N Q = O P, will have N M = M P, and O M = M Q. 3. The diagonal of a ſquare is incommenſurable with one of its ſides.

Add, 4. A very noble theorem in elementary geometry, firſt demonſtrated by Mr. Lagny, in the Memoirs de l'Academie Royale des Sciences, an. 1706, is that the ſum of the ſquares of the two diagonals of every parallelogram is equal to the ſum of the ſquares of the four ſides.

It is evident at firſt ſight, that the famed 47th propoſition of Euclid, ſo richly worth the hecatomb it coſt the author, is only a particular caſe of this propoſition: for if the parallelogram be right-angled, it follows of courſe, that the two diagonals are equal; and of conſequence, the ſquare of a diagonal, or, which is the ſame thing, that the ſquare of the hypothenuſe of a right angle, is equal to the ſquares of the two ſides. If a parallelogram be oblique-angled, and of conſequence, the two diagonals unequal, as is the more uſual caſe, the propoſition becomes of more extenſive uſe.

The demonſtration, in oblique-angled parallelograms, is thus:

thus: ſuppoſe the oblique-angled parallelogram A B C D (*fig.* 76) whereof B D is the greater diagonal, and A C the leſſer: from the point A, of the obtuſe angle D A B, let fall a perpendicular A E, to the ſide C D; and from the p int B another perpendicular B F to the ſide D C. Then are the triangles A D E, B C F, equal, and ſimilar, as A D is equal to B C, and the angles A D E, B C F, as well as A E D, B F C, are alſo equal; conſequently, D E is equal to C F. Now by Euclid, prop. 13. lib. ii. in the obtuſe-angled triangle B D C, the ſquare of the ſide B D is equal to the ſum of the ſquares of B C and C D, together with double the rectangle of C F by C D; and by the 13th, lib. ii. in the triangle D A C, the ſquare of the ſide A C is equal to the ſum of the ſquares of A D, and C D, abating double the rectangle of the ſame, C D, by D E, equal to C F. Conſequently, the former exceſs preciſely compenſating this defect, the ſum of the ſquares of the two diagonals is equal to the ſum of the ſquares of the four ſides. *Q. E. D.*

Hence, in every rhombus, or lozenge, knowing one ſide and a diagonal; the other diagonal will likewiſe be known: for, as the four ſides are equal, ſubtracting the ſquare of the given diagonal from quadruple the ſquare of the given ſide, the remainder is the ſquare of the diagonal required.

The propoſition is likewiſe of great uſe in the theory of compound motions; for, in an oblique-angled parallelogram, the greater diagonal being the ſubtenſe of an obtuſe, and the leſſer of an acute angle, which is the complement of the former, the greater will be the greater, and the leſs the leſs, as the obtuſe angle is the greater: ſo that if the obtuſe angle be conceived to increaſe till it be infinitely great, with regard to the acute one; or, which amounts to the ſame thing, if the two contiguous ſides of the parallelogram be extended directly, end to end, in a right line, the great diagonal becomes the ſum of the two ſides, and the leſſer one, nothing. Now, two contiguous ſides of a parallelogram being known, together with the angle they include, it is eaſy to find the ſubtenſe of that angle, *i. e.* one of the diagonals of the parallelogram, in numbers; which done, Mr. de Lagny's propoſition gives the other. Which ſecond diagonal, thus found, is the line that would be deſcribed by a body impelled at the ſame time by two forces, which ſhould have the ſame ratio to each other as the contiguous ſides have, and act in thoſe two directions; which diagonal the body would deſcribe in the ſame time, as it would have deſcribed either of the contiguous ſides in, if only impelled by the force correſponding thereto. This is one of the great uſes of the propoſition; for the ratio of two forces, and the angle they make, being given, it is frequently neceſſary to determine in numbers, the line a body, impelled by two forces, would deſcribe in a certain time. See COMPOSITION *of Motion*, and DYNAMICS. It was diſcovered by Ptolemy, that the rectangle of the two diagonals of any quadrilateral inſcribed in a circle, is equal to the ſum of the two rectangles contained under the oppoſite ſides: for the demonſtration of this property, ſee CIRCLE; art. 15.

All the ſides of a rectilinear figure, as A B, B C, C D, D E, E A (*fig.* 77.) and the angles O, and Y, being given to find the diagonals. In the triangle A B E, the ſides A B, and A E, being given, and the angle O, the angle A is eaſily found by trigonometry; and, from this, the diagonal B E. And, after the like manner, the triangle B C D is reſolved, and the diagonal B D found.

Since ichnographies, or plans, are beſt taken, by having all the ſides and diagonals, the uſe of this problem, in planimetry, is of ſome importance; eſpecially to ſuch as are willing to have their work accurate, though at the expence of calculation.

DIAGONAL *Motion.* Application of two, and three forces, in different planes, to produce every diverſity of rectilinear and curvilinear motion by the agency of machinery.

In moſt machines commonly uſed, the motions are either rotatory or reciprocating. Even the latter motion is ſeldom uſed, unleſs where the deſired effect cannot be produced by the rotatory movement. In fitting machines to ſuperſede, or diminiſh the neceſſity of human labour, mechanics have, as much as poſſible, ſtudied to reduce the reciprocating to the rotatory motion, wherever it appeared practicable. The cylindrical cards of an engine for carding wool or cotton, the barrel organ, and many other machines, are convincing proofs of this; and the reaſon of this preference is very obvious to every perſon at all converſant with the theory or practice of mechanics. In every reciprocating motion, the direction is ſo frequently reverſed, that the inertia, or vis inertiæ, as it is commonly called, muſt always produce a very conſiderable effect upon the momentum of the machine, and tend very much to impede its motion and diminiſh its power. Perhaps, after all the improvements for which mankind are indebted to Mr. Watt, in the conſtruction of ſteam-engines, this is ſtill the principal deſideratum, in that moſt uſeful and valuable machine. In rotatory motions, on the contrary, the movement being uniformly round a centre, the inertia, ſo far from impeding, tends always rather to increaſe the momentum, and conſequently, the power of the engine. Hence, where reciprocating motions are abſolutely neceſſary, the rotatory motion is generally combined with them, and fly or balance-wheels added to counteract the inequalities of power, and velocity produced by the inertia, while the direction of the motion is changed. But the rotatory movement is too limited in its operation to produce the infinite combination of motions of which machinery is ſuſceptible, and the reciprocating motions generally employed are moſt frequently confined to one direction. In the adaptation of machinery for the diminution or ſuperſeſſion of labour, thoſe machines are firſt conſtructed, where the mechanical powers may be applied in great force. Hence, in infant ſtates, cranes, water-mills, and ſuch engines are ſooner ſought for than clocks, watches, and other mechanical contrivances, more particularly ſuited to a refined ſtate of ſociety.

The motions which may be given to any piece of machinery are infinite, and the lines of direction in which the particular parts of the machine move, may be changed as often as the artiſt is inclined to do ſo. The following remarks, which are the reſults of a very long train of practical, and ultimately ſucceſsful experiments, may be of ſome uſe in directing the attention of mechanics to the conſtruction of a ſpecies of machinery, hitherto not generally known, or uſed in Britain; and only applied by thoſe foreigners who have practiſed it to purpoſes of mere ſpeculative and unproductive curioſity. The purpoſe for which the experiments were made, was to enable one perſon to work any given number of needles, for making flowers and other ornaments upon cloths, of various kinds, by the proceſs called tambouring. It is, however, equally ſuitable to any other art or manufacture where diverſified motion is required.

The theorem upon which the principle is founded, is thus expreſſed in the 1ſt and 2d corollaries to the 5th law of motion, as given in Mr. Motte's tranſlation of the Principia of ſir Iſaac Newton. "Corollary 1ſt. A body, by two forces conjoined, will deſcribe the diagonal of a parallelogram in the ſame time that it would deſcribe the ſides by theſe two forces apart. Corollary 2d. And hence is explained the compoſition of any one direct force out of any two oblique forces; and, on the contrary, the reſolution

of

of any one direct force into any two oblique forces; which compoſition and reſolution are abundantly confirmed from mechanics. Upon this principle, that eminent philoſopher demonſtrated the elliptical orbits deſcribed by the planets round the ſun, and the ſubject has ſince been moſt amply inveſtigated and carried much farther by Monſ. La Place.

To apply the principle to the conſtruction of any machine which requires the line of motion to be frequently, or inceſſantly changed, it is only neceſſary to uſe either two or three moving powers acting at the ſame time upon the body to be moved in different planes. For the ſake of convenience it will, in general, be found moſt advantageous that theſe planes ſhould be at right angles to each other. Conſequently, if two forces are employed, they will be in the direction of two ſides of a ſquare or parallelogram; and if three are neceſſary, they will be in the direction of three ſides of a cube, each ſide being at right angles to either of the others. The firſt of theſe is repreſented by *fig.* 12 *Plate* V. *Miſcellany*. If two forces be applied at the ſame time to move a body at B, and act upon it in the directions of the lines B C, B A, and if theſe moving powers produce equal velocity, the body at B will be moved by their joint application in the direction of the diagonal line B E, forming an angle of 45° with each of the lines B A, B C. If the force moving in the direction B C gives double the velocity of that which moves in the direction B A, the line, B D, will be deſcribed forming an angle of 36° 34′ with B C, and one of 63° 26′ with B A nearly, the latter being the complement of the former. From this it will be evident, that by varying the velocity given by the moving powers, every angle contained in the quadrant of a circle will be produced as may be required.

To effect this practically, and apply rotatory motions to produce ſuch lines of direction on the body moved, whether direct or reciprocating, two wheels, moving upon the ſame or different axes, are all that is required. Let it be ſuppoſed, that one of the two forces, moving at right angles to each other, is in a horizontal, and the other in a vertical direction. The firſt of theſe motions will be produced by the rotatory motion of the wheel, A, (*fig.* 13.) upon its axis B, and the horizontal motion will be communicated to the body C, which preſſes againſt the circumference or rim of the wheel by the action of the weight E, ſuſpended by a cord connected with C, and paſſing over the pulley D. The vertical motion is communicated in the ſame manner, by the rotation of the wheel, A, upon its axis, B, (*fig.* 14.) to the ſame body, C, by means of the lever, F, moving upon its fulcrum G, or any other ſimilar mechanical contrivance. If the wheels are placed upon the ſame axis, the combined application of their powers will be ſeen by inſpecting *fig.* 15. In *fig.* 14, the lever, F, is placed below the vertical wheel, in *fig.* 15. it is above, and acted upon by means of a cord, wire, or other connection, between the wheel, A, and the body C, upon which it acts. Theſe figures being profile elevations, and the wheel which gives the vertical motion being upon the ſame axis with that which produces the horizontal, muſt be ſuppoſed to be behind and concealed by it. *Fig.* 16, ſhews the axis in front, and the wheels in ſection.

The operation of theſe wheels, to produce either uniform, or diverſified motion, depends entirely upon the ſhapes into which their circumferences or rims are formed, and a knowledge of the manner of performing this operation, is the moſt important part of the buſineſs of the engineer, or mechanic, who plans them. Recurring to *fig.* 12, let it be ſuppoſed that in one revolution of the axis which carries the two wheels, the body acted upon is required to move from B to E, and again to return to B, deſcribing in both caſes the diagonal line B E. In this caſe the whole line of motion, forming an angle of 45° with the lines of each of the moving powers, their momenta muſt be equal. If the motion may, or ought to be, communicated at intervals, the wheels ſhould be conſtructed as a ſeries of concentric circles. In this way the wheel, A, (*fig.* 13.) is repreſented. It is divided into 12 equal parts, of which 1 and 12 are upon the ſame circle, or equally diſtant from the centre. From 1 to 6 the concentric circles approach towards the centre, the radius of each in ſucceſſion being leſs than that of the one preceding. From 7 to 12 the radii again increaſe to produce the returning motion upon the body C. Let C be a ſquare frame of any ſtout ſubſtance, ſo placed, or ſuſpended, as to move freely, either in a horizontal or vertical direction, and let a piece of paper or cloth be ſtretched upon it. Let there be alſo a fixed inſtrument placed at right angles to the plane of the frame (as a pencil), the point being in contact with the paper or cloth. Then, if the wheel, A, revolves upon its axis towards the body C, when the intermediate friction-wheel, H, is preſſing againſt the diviſion 1, the point will be at I, and when the diviſion 6 is in contact with the friction-wheel, the point will be at L, from whence, by the revolution of the other ſemi-circumference of the wheel from 7 to 12, it will be again at I. As repreſented in the figure the point would be half way between I and L, for the friction-wheel preſſes the diviſion 3. By theſe means the horizontal motion is effected. The wheel which gives the vertical motion to the ſame body would, by a revolution in the ſame way, bring the point from I to M, (*fig.* 14.), and again return it to I. Such would be the effect of each of the wheels acting ſeparately; but if their action is combined, the diagonal line, I K, will be produced by the preſſure of the point, and the motion of the frame C. It will be evident, that were the frame, C, ſtationary, and the point moved in the ſame direction by the action of the two wheels, the ſame effect would be produced; or the horizontal motion might be communicated to the one body, and the vertical to the other. The application of the moving power, therefore, is only a matter of practical conveniency, which may vary in different machines, and which, as it does not at all affect the general principle, muſt be left to the diſcretion of the engineer, and regulated by him as particular circumſtances may render expedient. The combined motion is repreſented, as already noticed in *fig.* 15, the vertical wheel being there concealed by the horizontal.

In theſe figures, the diviſions are equal, becauſe the angle is 45°, and the motion would only be communicated to the body C, at the inſtant when the friction-wheel, H, comes in contact with each diviſion. But if inceſſant motion be required, the deviation muſt be conſtant, and then the wheel will act like inclined planes applied to a circle.

In the machinery to which theſe experiments were applied, a great diverſity of figures was required, and theſe figures were often very minute. As the approaching to, or receding from, the centre of each wheel required to be done with greater accuracy than could be expected from the hand of any workman, an engine was contrived, ſimilar, in ſome reſpects, to that of Mr. Ramſden, for dividing mathematical inſtruments, and which ſhall afterwards be deſcribed.

If, inſtead of the line B E, it is required to deſcribe the line B D, it will be neceſſary that the deſcents and aſcents, which produce the vertical motion, ſhould be leſs than thoſe which give the horizontal; and by the common principles of right-angled trigonometry, theſe will be to each other in the ratio which the baſe line B C, bears to the perpendicular line C D, theſe being the ſines of the oppoſite angles. In the ſame way, every angle of the quadrant of a circle

ought

ought to be calculated, and applied by the engineer to the effect which he intends to produce. The length, intended to be given at every interval, in the machinery conſtructed, was $\frac{1}{32}$d, or .03125 of an inch. In the dividing and cutting-engine for the wheels, this was repreſented by the number 18, being the revolutions of a handle which effected the diviſions upon the rim of the wheel. When a horizontal motion was required, the wheel producing the vertical motion was made circular, ſo as to produce no effect upon the body to be moved. If vertical, the ſame was done with the horizontal wheel; and when oblique, a deviation from the circle was given to each, proportional to the angle of obliquity from a horizontal ſtraight line. Thus, the horizontal motion repreſented the baſe; the vertical motion the perpendicular; and the combined oblique motion the hypothenuſe of a right-angled triangle. As each of theſe muſt be made equal to $\frac{1}{32}$d of an inch, repreſented by the number 18, it became neceſſary to aſcertain the ratio which the hypothenuſe, whoſe meaſure was 18, bore to the baſe and perpendicular for every degree of a quadrant from 0° to 90°. Minutes and ſeconds were not reckoned, as being unneceſſary, and the neareſt degree, above or below, was taken. The table, calculated by the common trigonometrical analogies, making the hypothenuſe radius was as follows:

Table I. ſhewing the length of the baſe and perpendicular of any right-angled triangle, the meaſure of the hypothenuſe being 18, and calculated for every degree, from 0° to 90°.

	Baſe.	Perp.			Baſe.	Perp.	
0°	18.0	0.0	90°	23	16.6	7.0	67

21	16 8	6.5	69	44	13.0	12.5	46
22	16.7	6.7	68	45	12.7	12.7	45
	Perp.	Baſe.			Perp.	Baſe.	

The above table, calculated to every degree, from 0° to 90°, is adapted for cutting the rims of wheels for producing diagonal motion, to the 5760th part of an inch, by means of the engine afterwards deſcribed. The angles above 45° are the complements of thoſe below, as in common logarithmic tables.

Fig. 17, ſhews the angles of obliquity for every 10°. The baſe line, or horizontal motion, there becomes the co-ſine, and the perpendicular, or vertical motion, the ſine of the angles at the centre A of the quadrant BC. The triangles are repreſented by the radi, the baſe, and the perpendiculars drawn from the diviſions of the quadrant to the baſe, and numbered from 1 to 8.

The general principle being thus reduced to the common application of right-angled trigonometry, it may now be proper to deſcribe the cutting-engine, which is, probably, the only one of the kind in Britain, and of which repreſentations will be found in *Plate* VI.

Dividing and Cutting Engine.

This engine, as formerly noticed, is, in ſome reſpect, ſimilar to Mr. Ramſden's dividing engine. It alſo combines with this the properties of the common engine uſed by clock-makers for cutting the teeth of their wheels, excepting that, as conſtructed, it is not adapted for cutting oblique wheels, although the apparatus uſed for this purpoſe might very eaſily be added to it, if required. The engine made was entirely confined to the purpoſe of ſhaping the rims of ſuch wheels as have been already noticed, and never was applied to the purpoſes for which the common cutting engine is uſed. In *Plate* VI. *fig.* 18, is a ground, or horizontal plan, of every part of the engine which can be ſeen, when viewed from above, excepting ſome of the higher parts, which are omitted, for the ſake of ſhewing more diſtinctly the parts under them. The parts omitted in *fig.* 18, appear very plainly in the profile elevation, *fig.* 19. The length of the engine is four feet, and its breadth three feet, although theſe dimenſions ought, of courſe, to be varied, according to the diameters of the wheels required to be cut, by any engine conſtructed for a ſimilar purpoſe. The diameters of the wheels cut by this engine were 18 inches at the moſt remote point from the centres.

Like the common engine, this cuts by the revolution of a circular cutter upon its own axis; and as the cutters were thick (generally $\frac{1}{2}$ or $\frac{5}{8}$ths of an inch) the motion was taken from a ſhaft driven by the ſteam-engine, which alſo drove the reſt of the machinery. In ſmaller wheels, and where leſs power is required, the motion may be given by turning a winch applied to one end of the axis. The framing is of hard wood, four inches ſquare, and the joints faſtened by ſcrews and nuts. The upper part of this framing is repreſented at ABCD. To this upper part are ſcrewed four pieces of iron, G, G, G, G, which ſerve as ſupporters and guides for the iron frame EE; ſo that the frame may ſlide eaſily between them in a longitudinal direction. To one end of the wooden frame is ſcrewed a ſtrong piece of iron H, in which is a round hole to ſerve as a buſh for the neck of the ſcrew, which, paſſing through the iron frame at I, has its other end ſupported by another fixture to the wood work at K. The end of the large ſcrew is counterſunk to receive the point of a ſmaller ſcrew paſſing through the fixture at K, which may be ſcrewed up, when neceſſary, to keep the ſhoulder of the large ſcrew cloſe to the buſh, H, in which it revolves. When the ſcrew is turned round from right to left, the iron frame, working upon the ſcrew at I, will be puſhed forward between the guides; and when the motion of the ſcrew is reverſed, it will be again drawn back. Upon the end of the ſcrew is fixed a large wheel, L, which is worked by a worm or ſpiral ſcrew below, a ſmall part of which only can be ſeen at M, in *fig.* 18, but which appears very plainly in the profile elevation of the engine, *fig.* 19, and the perſpective view, *fig.* 20. The worm is fixed upon an iron axis, ſtretching acroſs the engine ſupported at either end by buſhes ſcrewed to the wood, and turned by the winch, or handle, N. Upon the axis is another ſmaller wheel, repreſented at N, the uſe of which ſhall be explained,

when

when the ratio of motion comes to be deſcribed. Upon the frame, E E, are two upright pieces of iron, F, F, through which paſs two centre ſcrews to ſerve as pivots, for another iron frame, O O, placed directly above the former. Acroſs this frame paſſes the axis of the cutter P, the ends of the axis alſo revolving upon centre ſcrews or pivots. Acroſs the engine, at a convenient diſtance, is fixed a ſtrong beam, Q, reſting upon the lower ſide rails of the wood, and ſecured by a ſtrong bolt at each end. Through the middle of this beam another centre ſcrew paſſes perpendicularly, the head being below, and the point above. Upon this is placed one end of the axis of the wheel or wheels to be cut, the axis being perpendicular, and the wheels horizontal, as repreſented at R. The apparatus by which the other end of the axis is ſecured, cannot be repreſented in the ground plan, *fig.* 18, but will be plainly ſeen in *figs.* 19 and 20.

By referring now to the profile elevation, *fig.* 19, the ſhapes and adaptation of all the parts already deſcribed will be perhaps more fully underſtood, the ſame letter always denoting the ſame part in both figures, as will appear by a very brief recapitulation.

A B C D, the wooden frame.
E, iron ſliding frame.
F, ſtandard for ſupporting the upper frame.
G, G, guides for the ſliding frame.
H, buſh for the ſcrew (partially hid, and therefore omitted in *fig.* 19.)
I, female ſcrew in the ſliding frame, (hid in *fig.* 19.)
K, fixture for the point of the ſcrew (hid in *fig.* 19.)
L, large wheel upon the axis of the ſcrew.
M, worm which works the large wheel.
N, handle of the axis of the worm (hid in *fig.* 19.)
O, upper frame placed in centres.
P, cutter and axis.
Q, Croſs beam for ſupporting the wheel to be cut.

The following parts, wholly, or partially concealed in the ground plan, *fig.* 18, will appear in the elevation, *fig.* 19.

T is a ſcrew paſſing through the front croſs bar of the upper frame; which, by coming in contact with the front croſs bar of the ſliding frame, acts as a ſtop to prevent the upper frame from being unneceſſarily depreſſed, after the cutter has paſſed through the part of the wheel, R, which it is to form. U is a ſtandard raiſed from the upper ſide rail of the wooden frame to carry a croſs-piece, V, through which a centre ſcrew paſſes to ſecure the upper end of the axis of the wheel R. W is a bearer placed upon any convenient part of the croſs-piece, V, to carry a lever, X, at the extremity of which a weight is ſuſpended, which, by overbalancing the upper-frame, raiſes it after it has been depreſſed by means of the connecting wire Y. The frame is depreſſed by preſſing down the lever Z, with the operator's foot, and this lever is connected with the frame by another wire between them. In *fig.* 19, the upright ſtandard, U, is repreſented by two lines, as if tranſparent, to ſhew the way in which the vertical axis of the wheel, R, is ſecured at the top.

Fig. 20, is a perſpective view of all that can be ſeen of the engine at the point of view where it is taken, excepting the top bearer, W, lever, X, connecting wires Y, and lever, Z, which being very plainly repreſented in *fig.* 19, are here omitted, to prevent confuſion from too many parts being crowded together upon ſo ſmall a ſcale. The point of ſight is at S, oppoſite to which, if the ſpectator will place his eye at the diſtance of $8\frac{1}{2}$ inches, he will have a correct view of the engine as it ſtands when at work. The ſame letters of reference are placed at each part of the engine which are in ſight, as in the two former figures.

If this engine is to be wrought by the application of any moving power, a faſt and looſe pulley may be placed on the axis of the cutter P, and the motion communicated from any ſhaft or drum, which moves at a proper velocity. If moved by the operator's hand, only one end of the axis is to be centered, and the other, paſſing through a buſh in the frame, is to be turned by means of a winch or handle. In conſtructing an engine of this kind, great pains muſt be taken that every part be very ſtrong and truly executed; for where the diviſions are ſo minute, the ſlighteſt vibration of any part will produce errors, which will render its operation totally uncertain. When uſing the engine, it is equally neceſſary that the cutter ſhould be always ſharp, and that too much preſſure ſhould not be applied by the foot during the operation. In ſome of the firſt trials made, a conſiderable deviation from the calculation was diſcovered after the wheels were cut. In conſequence of this, the engine was carefully re-examined, and the utmoſt pains taken that every part ſhould be both firm and correct. The experiment was then repeated, but ſtill a deviation took place, though ſometimes to a greater, and ſometimes to a leſs extent. After ſome fruitleſs attempts to correct this, the true cauſe was at length diſcovered. By the friction occaſioned by the preſſure and velocity of the motion of the cutter, both it, and the braſs rim to which it was applied, ſoon became prodigiouſly heated; and it then occurred, that the expanſion produced by the heat, both in the braſs and ſteel, muſt operate to a conſiderable degree upon diviſions ſo minute. To aſcertain how far this was the caſe, a wheel was rapidly cut, without paying any regard to the heating either of the braſs or the cutter. Both were then allowed to cool, and the cutter again applied gently to the different diviſions, the engine being ſhifted exactly as before, when thoſe diviſions which had been cut hot were found ſenſibly too deep. The wheel was then recut, or rather pared gently, for the deviations were not ſo great as ſenſibly to heat either the cutter or the rim in removing them, and upon trial the wheel ſo cut, was found exactly to produce the effect which had been expected to reſult from the calculation. Afterwards the wheels, after being cut, were always pared when cool, and the ſame error never occurred again.

The range of this engine is as follows: The ſcrew which moves the ſliding frame backwards and forwards was ſingle-threaded, and contained four threads in the inch. The large wheel, fixed upon the axis of the ſcrew, contained 144 teeth; and the worm, or ſcroll, being alſo ſingle-threaded, moved only one tooth at every revolution. It required, therefore, 144 revolutions of the ſcroll to produce one revolution of the ſcrew, and one revolution of the ſcrew moved the ſliding frame, and conſequently the cutter, $\frac{1}{4}$ of an inch; and as 144×4 is $= 576$, every revolution of the ſcroll moved the cutter only $\frac{1}{576}$th part of an inch. This was generally found ſufficient for common practice, but as it might ſometimes be neceſſary to be ſtill more minute, another ſmall wheel was fixed upon the ſame axis as the ſcroll, and divided into 10 equal parts, at each of which was formed a ſmall notch, and a ſlight ſpring, preſſing the circumference, ſerved as an index. Thus the tenth part of a revolution could be obtained, and conſequently the inch of motion of the cutter divided into 5760 equal parts. It is evident that the diviſion might be rendered more minute, almoſt *ad infinitum*; but this ſeemed to be fully as far as could be deſirable for any practical pur-

poſe, or as any machine executed by human ſkill could be expected to perform with accuracy.

The engine is wrought exactly as that of the clock-maker; excepting that the operator, between every cutting, ſhifts the ſituation of the cutter, by turning the ſcroll the number of times required.

To conſtruct wheels for producing diagonal rectilinear motion by this engine, and the table already given.

If a diagonal line, of one inch in length, and forming an angle of 24° with the baſe or horizontal line be required, by one-half revolution of the two wheels; and that the ſame line ſhould be again deſcribed in a contrary direction, by the revolution of the other half.

As every ſhift is ſuppoſed to be $\frac{1}{32}$d part of an inch, the ſemi-circumference of the wheel muſt be divided into 32 equal parts, or the whole into 64, and radii drawn from the circumference towards the centre. Then, to cut the horizontal wheel, (*fig.* 13 *Plate* V.) conſult the table, when againſt the angle 24° will be found, in the column marked Baſe at the top, 16.5. Beginning then at the diviſion marked 1, cut it as near to the circumference as convenient. Proceed to 2, and turn the ſcroll $16\frac{1}{2}$ turns; to advance the cutter ſo as to cut the wheel deeper, repeat the ſame operation upon 3, and ſo on ſucceſſively, ſtill advancing the cutter towards the centre of the wheel $16\frac{1}{2}$ turns of the ſcroll at each diviſion, until you arrive at 32, when the horizontal part of the line will be compleat. Cut 33 on the ſame circle as 32, and then turning the ſcroll the contrary way $16\frac{1}{2}$ turns at each diviſion, until you arrive at 64, the wheel will be compleat, and 64 will be on the ſame circle as 1.

To cut the wheel which gives the vertical motion.—Obſerve, after the wheel is divided, as before, into 64 equal parts, that the diviſion numbered 1 muſt be at right angles to that upon the horizontal wheel, becauſe the point of motion is under the centre, (*figs.* 14 and 15. *Plate* V.) and that of the cutter on a level with it. Again conſulting the table, againſt 24°, in the column marked Perp. is 7.3. Cut as before the firſt diviſion, as near to the rim as convenient, and advance the cutter $7\frac{3}{10}$ turns at each diviſion to 32. Bring it back the ſame number of turns to 64, and the wheels will be ready for work. When the wheels are applied to the body to be moved, every revolution will then deſcribe a ſtraight line, forming an angle of 24° with the plane of the horizon, and re-deſcribe the ſame line returning to the point from whence it ſet out. Any other angle will be produced preciſely in the ſame way, by uſing the numbers in the table for the turns of the ſcroll. When the angle exceeds 45°, what was formerly the baſe becomes the perpendicular, and *vice verſâ*, as marked at the bottom of the reſpective columns, and as in common trigonometry.

Of Curvilinear Motion.

The mere production of diagonal ſtraight lines would be too limited for the ornamental varieties to which machinery of this deſcription ought to be applicable. The late Mr. Hogarth has pronounced a curve to be the line of beauty, and the taſte of moſt nations, the Chineſe perhaps excepted, ſeems ſtrongly to juſtify his aſſertion. In machinery of this deſcription, the deviation of the line deſcribed from one angle to another may be made ſo frequent and minute, as to deſcribe the circle, the ellipſe, the parabola, or any other curve, regular or irregular, with a very great degree of accuracy. In deſcribing circles, or circular curves, the plan adopted was to conſider them as inſcribed polygons, of a number of ſides proportionate to the circumference of the circle required. The inſcribed polygon (*fig.* 17. *Plate* V.) although only containing 9 ſides in the quadrant, or 36 in the whole circle, does not deviate very far: and had each of theſe ſpaces in the circumference been again divided into 10, or even into 5 equal parts, the deviation of the polygon from the circle would have been totally imperceptible to any human eye.

To aſſiſt in calculating the circles which formed the curved lines, it was neceſſary to aſcertain the diameters, from which the meaſure of the circumferences being found by the common geometrical analogy, the number of diviſions in the wheels could be alſo found. It is evident that every ſide of an inſcribed polygon, with the two radii, forms an iſoſceles triangle; and that therefore the acute angle at the centre of the circle being found, the other two angles, which are equal to each other, may alſo be found, by ſubtracting the angle at the centre from 180°, and dividing the remainder by 2. The following rules were therefore reſorted to upon this principle, and as the meaſure was $\frac{1}{32}$d of an inch, that fraction was made the ſtandard of unity, and all the ſubſequent calculations made in thirty-ſecond parts.

Rules.—1. Divide 90°, being the meaſure of the quadrant of a circle, by the number of ſides of a polygon inſcribed in that quadrant, or by the fourth part of the ſides which compleat the whole inſcribed polygon. The quotient will give the meaſure of the acute angle at the centre.

2. The acute angle being found by the preceding rule, is to be ſubtracted from 180°, and the remainder, divided by 2, will give each of the angles at the circumference which are equal, and conſequently the angle which one of them makes with the baſe or horizontal line will be found.

3. As all the triangles are ſimilar, the angles of all at the circumference are equal. And as by the twenty-ninth propoſition of the firſt book of Euclid's Elements, alternate angles are equal to each other, the meaſure of the acute angle being ſucceſſively ſubtracted from each of the other angles, will give every angle of the polygon progreſſively, or add the acute angle at the centre for the next centre angle, and ſubtract it for the angle at the circumference.

Referring again to *fig.* 17. *Plate* V., the firſt angle B A 1 is one of 10°. By the firſt of the above rules, when 90° is divided by 9, (the number of polygonic ſides in the quadrant) the quotient gives 10°. By the ſecond rule 180° − 10° = 170°, and 170° ÷ 2 = 85°. The meaſure of the angle A B 1 is therefore 85°. Again, the angle, B A 2, is 20°, and the angle, A 1 2, is equal to the angle A B 1, and conſequently 85°; but the angles, A B 1, and A 1 *a*, being alternate angles, are equal to each other. Conſequently, 85° − 10° = 75°, the meaſure of the angle *a* 1 2. In the ſame way all the other angles will be found, and when found, the table already given will ſhew the turns of the ſcroll required to cut the baſe and perpendicular lines neceſſary to produce a diagonal or hypothenuſe line equal to 18, *viz.* baſe 1.5, and perpendicular 17.9. If a different meaſure is wanted, it may be got by common proportion. For, if the hypothenuſe is to be 15, then as 18 : 15 :: 1.5 : 1.25, for the baſe; and as 18 : 15 :: 17.9 : 14.805, for the perpendicular.

The following table gives the diameters and circumferences of a ſeries of circles repreſented by polygons, from a diameter of $\frac{6}{32}$d of an inch, to one of $\frac{64}{32}$d, or two inches. The firſt column contains the meaſure of the diameter; the ſecond, that of the circumference; the third, the whole number of ſides of an inſcribed polygon; and the fourth, the number of ſides contained in a quadrant of the circle.

TABLE II.

Diameter.	Circum.	Neareſt Polygon.	Quadrant.
6	19	20	5
8	25	24	6
10	31	32	8
12	38	36	9
14	44	44	11
16	50	52	13
18	57	60	15
20	63	64	16
22	69	72	18
24	75	76	19
26	82	84	21
28	88	88	22
30	94	96	24
32	100	100	25
36	113	116	29
40	126	128	32
44	138	140	35
48	152	152	38
52	163	164	41
56	176	176	44
60	188	188	47
64	201	204	51

In the annexed table, the polygon has been in general taken above the meaſure of the circumference, but the deviation is very ſmall, and cannot affect any practical calculation.

The number of ſides being found by this table, that which follows will give the angle which each ſide forms with a horizontal ſtraight line, omitting minutes and ſeconds, and taking the neareſt degree. If greater minuteneſs be required, which will be ſeldom, if ever, neceſſary, the calculation may be carried out even to decimals of a ſecond, by the rules already given. The firſt column contains the ſides in the whole circle, and the ſecond, thoſe in the quadrant, correſponding to table II. The remaining columns, numbered from 1 to 26, give the degrees in the ſucceſſive angles. By the firſt angle is always underſtood that neareſt to the horizontal diameter of the circle, as A B 1, *fig.* 17. *Plate* V. up to a polygon of 100 ſides, the whole angles in the quadrant are given; above that, they are only carried to the octant, or to 45°. It will, however, be obſerved, that the angles omitted are the exact complements of thoſe given, the extreme angles forming together 90°, and ſo of the others converging towards the middle. Thus, in the laſt line, where 51 angles are required to complete the quadrant, 26 only are given, and the 26th is the mean angle, or 45°. The firſt angle is 89°, whoſe complement being 1°, that is the meaſure of the 51ſt. The ſecond being 87°, its complement of 3° gives the 50th, and ſo of all the others.

A ſingle example will probably be ſufficient to elucidate the uſe of all the three tables, after the previous deſcriptions. Let it be required to form a circle by means of machinery, the diameter of which ſhall be half an inch. As $\frac{1}{32}$ is the meaſure of unity, the diameter will be repreſented by 16 in table II. By inſpecting the table it will appear, that the circumference is 50, the neareſt polygon 52, and the ſides contained in one quadrant 13.

By table III. we find, againſt the numbers quoted, for the

1ſt	-	Angle	-	86°

Let

Let us then ſuppoſe, that in deſcribing this circle, we commence our operation at the horizontal diameter, and at the right hand, as at B in *fig.* 17. *Plate* V.

Let us alſo ſuppoſe, that the frame which carries the ſtuff upon which the circle is to be deſcribed, is moveable both in a horizontal and vertical direction, as in *figs.* 13, 14, and 15. The calculation will then ſtand as follows:

1ſt Quadrant.

	Diviſion.			Baſe.		Perpendicular.

which compleats the circle.

In the above calculation, the word *riſe* is uſed when the rim of the wheel is to recede from the centre, and the word *ſink*, when it is to approach it. In the firſt quadrant of the circle, or polygon, as the point is taken from the right-hand, the frame muſt be moved by the horizontal wheel towards the right. Had the frame been ſtationary, and the tracer required to move, the motion would, of courſe, have been inverted. The riſing motion is, therefore, given to the horizontal wheel, until the frame has come into contact with the other end of the ſemidiameter, at the laſt diviſion of the ſecond quadrant.

In the ſame way, the vertical wheel muſt ſink the frame to raiſe the tracer; and this is done during the firſt quadrant, when it has arrived at what may be called the vertex. It then riſes for a whole ſemi-circle to the laſt diviſion of the third quadrant, when it again ſinks to compleat the circle. The angles of all the quadrants are the ſame, but alternately inverted. Their application to the dividing and cutting engine is taken from table I. By ſimilar means, a circle of any radius or diameter may be deſcribed, and conſequently any arc or curve of a circle. The whole of each wheel, in the inſtance given, muſt be divided into 52 equal parts, both for the horizontal and vertical motion. It will ſeldom be neceſſary to form curved lines, which are not portions of circles, where mere ornament is to be conſulted; but if it ſhould, it is evident that the ellipſe, the parabola, and the hyperbola, may be reduced to a ſeries of triangles in the ſame way as the circle, and the wheels cut accordingly, to form any of theſe geometrical figures, or any portion of either.

A few examples of the application of this kind of machinery, to produce various kinds of figures, compoſed of ſtraight, or curved lines, or of a combination of both, may ſerve further to illuſtrate the ſubject; and for theſe the reader will be pleaſed to conſult *Plate* VII.

When ſuch curves only as will produce a pleaſing effect to the eye are required, they may, almoſt always, be approximated very nearly to arcs of circles of various radii, as in the example, *fig.* 21. The three leaves of this flower conſiſt entirely of arcs of circles, the centres of which are pointed out by the letters of reference; and the angles ſubtending the arcs are repreſented by dotted lines. The middle leaf of the flower, it will appear, is formed by four circular curves, the centres of which are reſpectively at A, B, C, and D. In the ſame way, five curves, whoſe centres are at H, I, B, K, and L, form the left hand leaf; and three curves centered at G, E, and F, the right-hand leaf; the whole flower containing 12 curves.

It may now be proper to inveſtigate the conſtruction of two wheels, adapted to form this flower, the means of reducing it to the tables, and applying the cutter.

Let the tracing of the lines be commenced with the middle leaf, beginning at 5. The firſt arc will then be from 5 to 4, the centre of which is at A. By a common diagonal ſcale of 400 parts to the inch, the radius, from A to 5, meaſures about 334 of theſe parts, aud the diameter, of courſe, 668. This number, divided by 12.5, will reduce the meaſure to 32d parts, to adapt it for the engine. This will be found to be 53.44, and the fraction may be omitted, ſo that 53 will be the meaſure of the diameter of the arc. By table II., the neareſt approximation to this is 52, and the circumference of the whole circle 165. The arc meaſures 78°,

namely,

namely, 25° from 5 to a horizontal line drawn through the centre A, and 53° from the ſame line to 4. Therefore, as 360° : 165 :: 78° : 35,75 being the number of polygonic ſides contained in the arc. This, by the neareſt integral number, may be taken at 36 ſides. By table III. the neareſt number for the whole circle is 164; and as the arc contains 78°, or 36 of theſe ſides, the angle at the commencement, 25° under the horizontal line will be found by the following proportion. As 78° : 36 :: 25° : 11.5384, or, in even numbers, 12. The ſides under the horizontal line are therefore nearly 12, and thoſe above will be 24, to compleat 36. For the firſt ſide therefore, take from table II. the 12th angle oppoſite to 164; then the 11th, and ſo on, until you have got to the 1ſt angle, which is the neareſt to the horizontal line. This gives the meaſure and angles of the 12 ſides below. Taking the ſame angles from 1 to 24 incluſive, and beginning at 1, will give the 24 ſides above, and theſe compleat the arc. This arc will then ſtand thus:

		Horizontal.		Perpendicular.
1ſt	Angle below 65°	Riſe 7.6	Sink	16.3
2d	—— 67	— 7.0	—	16.6
3d	—— 69	— 6.5	—	16.8

23d	—— 41	— 13.6	—	11.8
24th	—— 39	— 14.0	—	11.3

The firſt arc being compleated, we proceed to trace the 2d from 4 to 3, containing an angle of 76°; *viz.* 48° below and 28° above the horizontal line, drawn through the centre B. This arc being of the ſame radius as the former, the number of polygonic ſides in the whole circle will alſo be 164; and as the arc contains 76°, the ſides contained in it may be taken at 35. Of theſe, 22 will be included in the 48 degrees below the horizontal line, and 13 in the 28° above. As formerly, therefore, commence with the 22d column, and proceed ſucceſſively to the firſt, for the 22 angles below, and then, beginning again at the 1ſt, go on to the 13th for the angles above. The angles will then be 43, 45, 47, 49, 51, 53, 56, 58, 60, 62, 65, 67, 69, 71, 74, 76, 78, 80, 83, 85, 87, 89 degrees below; and 89, 87, 85, 83, 80, 78, 76, 74, 71, 69, 67, 65, 62 degrees above, which compleats the arc. The numbers for cutting may then be taken, as before, from table I. The arc, from 3 to 1, whoſe centre is at C, may next be calculated in the ſame manner, and that, from 1 to 2, whoſe centre is at D, which compleats the middle leaf.

The arcs of the whole flower, and their reſpective centres and angles, are as follow.

Arc.		Centre.	Diameter in 32d Parts.	Circumfer. in 32d Parts.	Angles below.	Angles above.	Whole Angles.	Polyg. Sides in the Circle.	Polyg. Sides in the Arc.	Sides below.	Sides above.	Complement. Angle.	1ſt Angle.
Middle Leaf.	5 to 4	A	53	165	25°	53°	78°	164	36	12	24		65°

The

The whole number of ſides contained in the 12 arcs, of which the flower conſiſts, will be found by adding the numbers in the 9th column, containing the polygonic ſides in each arc, to amount to 550. This, therefore, is the number of equal parts into which each wheel is to be divided, previous to the cutting. If the machine will contain wheels of ſufficient diameters, all this will be moſt eaſily effected by two wheels; but when circumſtances do not admit of this, two or more wheels may be uſed for each of the motions; each of theſe wheels forming a certain portion of the figure by its revolution. In this caſe, the machinery communicating the motion from the wheels to the body which is to be acted upon, muſt be ſo conſtructed, as to be ſpeedily and eaſily moved from one wheel, and placed in contact with the others ſucceſſively. This may be effected by a dextrous engineer in a great variety of ways, and the ſuperiority of any one plan over others, muſt depend ſo much upon particular circumſtances, ariſing both from the conſtruction of the machine, and from the ſpecial purpoſe for which it is deſigned, that it would be equally difficult and fruitleſs here, to ſpecify preciſe modes of doing this.

In the 4th, 8th, 9th, 10th, 11th, and 12th arcs laid down in the preceding calculation, no part of the arc croſſes a horizontal line drawn through the centre, the whole being either above or below. As the table, No. 3, is calculated for a whole quadrant, it is, in this caſe, proper to meaſure the complementary angle between the horizontal line, and the line which ſubtends the arc, and to calculate the number of polygonic ſides contained both in it and in the arc. The number in the complementary angle is then the diſtance of the commencement of the arc from the horizontal line, and, of courſe, ſhews by the table the firſt angle of the arc. When an arc approaches towards the horizontal line, the ſucceeding angles muſt be taken from right to left, and when it recedes from it, from left to right.

When the arc does not croſs the horizontal line, the complementary angles will be found in the 12th column.

In the machinery conſtructed for the purpoſe of tambouring, upon theſe principles, the figures were moſt frequently ſmall, and the rows placed diagonally, ſo as to form a kind of diamond. A ſpecimen of this application of the wheels will be found in *fig.* 22. In this figure, eight flowers, exactly ſimilar to each other, are repreſented; excepting only, that the two flowers in the ſecond, or middle row, are inclined in a contrary direction to thoſe in the firſt and third rows; that is to ſay, that where the one row points towards the right hand, the next points towards the left; and the ſame is the caſe in every alternate row, however numerous they may be. It is unneceſſary to enter much into detail about the means of effecting this, for the whole difference is comprehended in the horizontal motion, and the calculation of both flowers is exactly the ſame. In cutting the wheels, it is only neceſſary to reverſe the motion of the ſcrew which regulates the cutter, and to ſubſtitute the word *riſe*, for *ſink*, and *vice verſâ*, according to the explanation already given. The mode of placing every row between that next to it, is effected alſo by the horizontal wheel. One row is included in the circumference of the ſemi-diameter of the wheel, and the circumference of the other ſemi-diameter is reduced as much nigher to the centre, as the diſtance of one of the vertical lines in the plate is from the next line.

Another plan was ſometimes uſed. The wheels were cut exactly of the ſame comparative diameters, and the centering or boſoming of the alternate rows was produced, by uſing two intermediate friction-wheels between the moving-wheels and frame acted upon. This was found very correct, for the two friction-wheels which were alternately uſed, each being employed for its reſpective row, were turned of different diameters. But as time was loſt in engaging the one and diſengaging the other at every row, the former plan was at laſt preferred and adopted.

The formation, therefore, of one flower includes that of all the reſt; for the formation of the remaining figures is effected merely by the diſpoſition of a greater number of points or tracers. In the inſtance for which theſe experiments and calculations were firſt made, a row of needles, or rather hooks, were placed in a frame in a horizontal poſition, and the cloth being ſtretched vertically oppoſite to their reſpective points, was ſhifted by the agency of the two wheels. Behind was another horizontal apparatus, for ſupplying the threads neceſſary to the operation. When it was neceſſary, therefore, to ſhift, it was found eaſier to ſhift the vertical frame containing the cloth, than the frames both before and behind. When ſimilar machinery is employed to move a ſingle point, or tracer, it is perhaps better to communicate the motion to the point, and to leave the ſurface acted on ſtationary.

In the middle figure of the uppermoſt line, the angles are drawn to the centres, as in *fig.* 21. They conſiſt of four arcs, or ſegments of circles, as follow:

Arc 1 to 2	Centre	*b*	Diameter	$\frac{20}{3\frac{1}{2}}$	Arc	95°
3 to 4	- -	*a*	- -	$\frac{20}{3\frac{1}{2}}$	-	225
5 to 6	- -	*d*	- -	$\frac{16}{3\frac{1}{2}}$	-	56
7 to 5	- -	*c*	- -	$\frac{16}{3\frac{1}{2}}$	-	90

The dotted lines drawn upon the figure, ſerve both to aſcertain the reſpective diſtances of the flowers, to ſhew the angles ſubtending the arcs, and alſo the complementary angles.

The angle *b a d* ſubtends the arc 1 to 4, which contains 225°.

The angle 2 *b* 1, the arc 1 to 2 of 95°
The angle 5 *c* 6, the arc 5—6 of 56
The angle *a d* 5, the arc 7—5 of 90

Two ſmall arcs remain to join the points of the leaves. They may be taken as ſemicircles, the diameters of which are each $\frac{8}{3\frac{1}{2}}$. The firſt upon the upper leaf commences at 45°; the ſecond on the lower leaf at 0°. Each, of courſe, is 180°, or two quadrants. Every other part neceſſary will be found by meaſurement, or by referenee to the tables, as in the former caſe, and thus any figure may be produced.

In *figs.* 23 and 24, are given ſpecimens of the application of theſe wheels to produce *writing*, as in the automata, which are exhibited as matters of curioſity. The firſt requires only two wheels; the ſecond three wheels, for the purpoſe of making the faint and bold lines. In theſe, the tracer, reſembling that conducted by the human hand, may either be ſuppoſed to move, and the tablet to be ſtationary and horizontal, as in common writing, or the table perpendicular and the pen horizontal.

It is not within the compaſs of this deſcription to enter into any examination of the proportions of the various letters of the alphabet, as uſed in that kind of hand-writing moſt approved in Britain. This belongs more properly to the analyſis of the art of penmanſhip, than to an eſſay or treatiſe on the production of diverſified motion by the agency of machinery. In general, however, it may be proper, ſhortly, to explain how the letters given as ſpecimens are conſtructed, and their application to the moving wheels, without at all entering into any diſcuſſion whether theſe are proper forms; for, from the very nature of the machinery, and the deſcriptions already given, it will be evident, that any other form might be produced with equal eaſe, and that Hebrew, Greek, or Arabic characters may be effected as well as thoſe uſed in Britain. The conſtruction of the letter O is as follows; and this alſo comprehends part of the letters *a*, *c*, *d*, *e*, *g*, and *q*. The letter O is repreſented by an ellipſe, the greater diameter of which is an inch, or in the

the integers formerly uſed, 32. The leſſer diameter has been taken at 18.4. The inclination of the greater diameter paſſing through the foci, has been placed at an angle of 65° with the baſe line.

Theſe being premiſed, it becomes neceſſary to calculate the triangles which will form a near approximation to the curvature of an ellipſe of this deſcription, and of the angle of obliquity formed by the hypothenuſe of each triangle with the baſe line. In order to this, nine triangles have been conſtructed, forming a kind of polygon of 36 ſides. The lengths, reſpectively, of nine portions, both of the greater and leſſer ſemidiameters of the ellipſe, have alſo been calculated, and from theſe, the angles of obliquity formed by each ſucceſſive hypothenuſe with the baſe lines, have been trigonometrically aſcertained, as alſo the lengths of the reſpective hypothenuſes, and, of conſequence, of very near approximation to the circumferential curve of the ellipſe.

The manner in which theſe calculations have been done is as follows:

Let the half of the greater diameter = 16
And the half of the leſſer = 9.2

As the ellipſe is conſtructed by ſetting off lines upon both diameters, let theſe be done at every 10°, and drawing lines through the points thus found, a ſeries of nine triangles will be formed in each quarter of the ellipſe, the baſes and perpendiculars of which will be reſpectively as follow, (32d parts being ſtill conſidered as integers, and the fractions as decimals.) The greater ſemidiameter is here conſidered as the perpendicular, and the leſſer as the baſe.

Triangle.	Baſe.	Perpendicular.	Hypoth.	Acute angle with the baſe line.
1	.14375	2.80	2.804	87°
2	.4025	2.65	2.693	81
3	.69	2.55	2.64	75
4	.92	2.3	2.48	68
5	1.12125	1.95	2.3	58
6	1.3225	1.6	2.081	50
7	1.46625	1.2	1.907	39
8	1.52375	.7	1.656	25
9	1.61	.25	1.598	9
Total	9.2	16.00	20.159	

Fig. 17*. *Plate* V. is a quarter of an ellipſe of theſe proportions. The ſcale is five times the ſize of that calculated upon, integers being there taken as 8th parts, inſtead of 32d parts. The line A B is the leſſer diameter or baſe line, B C the greater diameter, and the lines from A to C the hypothenuſes of the triangles which form the approximation to the elliptic curve.

From theſe reſults it will appear, that the quarter of the elliptic curve meaſures 20.159 in 32d parts. But as there are only nine triangles in the polygonic figure, in each quarter, it has been thought beſt to allow 21 ſides for the quarter, or 84 for the ellipſe. Dividing therefore the quarter into 21 parts, the following diviſion of the angles will be very near the truth. Were nearer approximation, however, neceſſary, the calculation might be brought ſtill nigher by ſetting off the ſemidiameters in 21 diviſions by the line of ſines, and calculating each upon the preceding plan.

1ſt	Side	Angle with baſe line	89°
2d	do.		87
3d	do.		85
4th	do.		83
5th	do.		80
6th	do.		77
7th	do.		74
8th	Side	Angle with baſe line	72°
9th	do.		70
10th	do.		65
11th	do.		60
12th	do.		56
13th	do.		52
14th	do.		50
15th	do.		45
16th	do.		37
17th	do.		30
18th	do.		25
19th	do.		17
20th	do.		9
21ſt	do.		4

Thus the calculation would ſtand, were the ellipſe placed upright, and the leſſer diameter the ſame with the baſe line. But as it is aſſumed that the ellipſe muſt be inclined until the greater diameter will form an angle of 65° with the baſe, the complement of that angle, or 25°, muſt be ſubtracted from each of the angles. The 18th angle will then be 0°; the 19th, 8°, under the baſe; the 20th, 16°; and the 21ſt, 21°. The angles being thus found, the firſt table will give the rules for cutting as uſual.

The only other example relating to penmanſhip, or the conſtruction of writing automata, which it appears neceſſary or proper to trouble the readers of this article with, is the letter *i*; for the curvilinear part of this ſeems, in combination with the *o*, to form almoſt every letter of the manuſcript alphabet; *a*, *d*, *m*, *n*, and moſt others will be found very ſimilar, and a practical way of conſtructing the reſt will afterwards be inveſtigated. Of a great part of theſe letters, much is compoſed of ſtraight lines of different lengths; but all, by the aſſumption, form angles of 65° with the baſe, and of courſe all the ſtraight lines, or ſtraight parts of lines, muſt be cut to that angle, the only difference being their reſpective lengths, which may eaſily be meaſured. It only remains, therefore, to calculate the curvilinear parts, which are all ſimilar, and therefore one calculation will anſwer for the whole. In the word *man*, which has been taken for an example, the curves at the top and bottom of the letters *m* and *n* are preciſely the ſame; the remaining parts of theſe letters are rectilinear. The ſame is the caſe with that part of the letter *a*, which is formed by adding an *i* to the elliptical part, or *o*. The oblique lines, being equal to the larger diameter of the ellipſe, are alſo expreſſed by 32. The dotted lines, which bound and interſect the writing acroſs the plate, will ſerve to ſhew how the centres of the circular arcs which form the curves have been taken: theſe lines are diſtinguiſhed by the numbers 1, 2, 3, 4, and 5. The rectilinear oblique lines are placed between the croſs lines 2 and 4. The curves conſiſt of two arcs; the arc, *c d*, being a ſemicircle of a ſmall diameter, the centre of which is at *f*. The dotted line, *c f d*, is the diameter, and is parallel to the leſſer diameter of the ellipſe. The remaining curve, *d e*, is a ſmall arc of a large circle, the centre of which is at *g*. The arc, *h i*, is taken from the centre *k*. All the other ſimilar arcs are taken with equal radii from points in the parallel ſtraight lines at the top and bottom of the figure. It ſeems unneceſſary to repeat in detail the particular angles which form theſe arcs, for they will be found preciſely in the ſame way as the arcs formerly deſcribed.

From the above it is evident, that motion in the ſame plane may be diverſified to unlimited extent, by the joint application of two forces; and it has been the object of theſe deſcriptions to point out means of effecting this with great preciſion. The addition of a third power, acting in a line at right angles to this plane, renders the diverſity of motion

motion abſolutely unlimited, and is merely an extenſion of the former principle.

Application of Three Forces.

As already ſhewn, the application of two forces, if uniform, will produce the diagonal of a ſquare or parallelogram. If three are applied in the directions of the three planes of a cube, the dotted line A B in the tranſparent cube, (*fig.* 12. *Plate* V.) will be produced, provided all the moving powers act with equal velocity upon the body moved. The firſt force acting in the direction of the line A B, and the ſecond in that of the line B C, would produce a motion from A to C, but by the addition of the third power, moving in the direction of the perſpective line C E, at right angles to the two former, the body again diverges from the line produced by the two firſt powers, and will arrive at E.

Three wheels, which produce motion in theſe different ſtraight lines, muſt therefore effect every poſſible direction of motion, and the third wheel is to be cut preciſely upon the ſame principles as the former two.

As the writing and drawing automata are entirely machines conſtructed upon principles ſimilar to the foregoing, a ſhort account of the nature of a plan by which ſuch a machine may be made, may both ſerve to illuſtrate this, and to direct the attention of mechanics, who have hitherto confined the application of their talents to the planning and conſtruction of uniform and rotatory motion, to a ſubject ſuſceptible of endleſs variety, and which may ſurely be beneficially applied to many uſeful and elegant purpoſes of arts and manufactures.

As this is merely an illuſtration of a general principle, invented and drawn by the author of this article for the purpoſe, it may, and probably will, not be found to correſpond with thoſe conſtructed by others; but if the general principle is aſcertained to be correct, it will be of ſervice in demonſtrating to ingenious mechanics how ſuch operations may be performed. Three motions being neceſſary to produce the effect required, let the ſpectator be ſuppoſed to be placed immediately behind the automaton which is to write or draw a certain given figure, by the agency of three wheels, ſuch as thoſe already deſcribed. The automaton will be conſidered as a mere piece of framing, ſhaped in the outſide to repreſent a human figure. The moved parts are his right arm, above and below the joint at the elbow, the part from the elbow to the points of the fingers being ſolid, and the pen, or pencil, with which he writes, ſcrewed or fitted into the hand. Before him let there be a cubical box, repreſenting the table upon which he writes, and fitted to contain the machinery by which the right arm is to be moved. The ſeat, body, head, and left arm, may alſo be conſidered as hollow framing, within which the motion may be communicated. The tablet being placed horizontally before him upon the box or table, the motions required will be as follow: The tracing of the lines upon the tablet will be effected by the combination of two motions at right angles to each other, and theſe may be given by conſtructing within that part which repreſents the ſhoulder of the figure, an apparatus reſembling what is called by mechanics a *univerſal joint*. The third motion at right angles to the plane of the tablet, will ſerve to elevate or depreſs the point of the pen or pencil, in order to produce bold or faint lines, as may be requiſite, and to lift the pencil entirely from the tablet when a blank or ſpace is to be left, or when the hand of the automaton is to be ſhifted from one place to another. The direction of the firſt force may be ſuppoſed to be ſuch as would produce a motion from the top to the bottom of the tablet or paper, as theſe words are generally underſtood when applied to writings or books. The ſecond motion ought to give a direction from left to right, which will be, of courſe, at right angles to the former, and both may be reverſed at pleaſure by the ſhape of the wheels. The third motion will lift the hand and pencil from the tablet, to produce the bold and faint lines, and to diſengage it when neceſſary.

Figs. 25 and 26. *Plate* VII. are repreſentations of ſuch a figure. *Fig.* 25, is an elevation of the automaton, as ſeen behind, and the moving and moved parts are as follow. The framing is repreſented by the figure diſtinguiſhed by the letters A, A, A, A. The firſt motion from the top to the bottom of the tablet is effected by the wheel, B, revolving upon the axis G. This wheel gives motion to the lever, E, reſting againſt the wheel upon a level with the centre, and neareſt to the ſpectator's eye. When the axis revolves upon its centre, the wheel, by communicating motion to the lever E, which is connected by a joint with the ſmall horizontal axis fitted in the frame H, continues the motion to the lever F, repreſenting the bone of a human arm from the ſhoulder to the elbow. This again gives motion to the lever, which repreſents the bones below the elbow, and conſequently to the pencil by which the writing is made. Thus the firſt motion, from top to bottom, is produced. The ſecond motion, from left to right, is done by the wheel, C, upon the ſame axis. By the revolution of the axis, this wheel acts upon the lever, I, which moves the frame, H, and the lever, F, in the direction required. The lever, I, reſts upon the upper part of the circumference of the wheel, C. The third motion, for raiſing or ſinking the pencil, is derived from the wheel, D, which, acting upon the levers connected at the joint, K, move the perpendicular lever, L, connected with the part of the right arm below the elbow. This connection will be ſeen more plainly in *fig.* 26, which is a profile ſection of the ſame machine. The lever, L, is here connected with that which paſſes through the lower part of the arm, and which is marked by the letter M. The box which repreſents the table is diſtinguiſhed by N, and the ſeat by O, in both figures. The machinery thus conſtructed may be concealed by any covering which gives it the appearance of a human figure, as in the outline ſketch which ſurrounds it. The levers may be kept in contact with the wheels either by weights or ſprings, as may be found moſt convenient. The whole may be moved by a ſpring, as in a common watch or time-piece, and the velocity of the motion regulated by a balance-wheel, pendulum, or ſimilar mechanical agent. In theſe ſketches all that part of the machinery which is common to other rotatory movements, is omitted; and as it is merely meant to give the reader an idea of the general principle of the whole, is confined within the compaſs of the automaton. When a great number of movements is required, it is plain that many more wheels may be added, and for this there is ſufficient room within the boxes which repreſent the table and the ſeat. The joints which are diſtinguiſhed by the letters, H, I, and K, are only ſingle, to allow a motion from left to right, and *vice verſâ*; and the perpendicular levers paſs through a croſs bar P, with notches to ſerve as guides. Theſe guides confine the levers, I and K, in every direction. That which guides the lever, E, being ſo placed as to allow a motion at right angles to the others, muſt be conſtructed ſo as not to confine the motion of the lever from the front to the back of the machine, but to prevent the lever from diverging from the wheel. This is ſhewn at P, in both figures.

From the deſcriptions given, it is preſumed that readers, converſant with the ſtudy of the theory and practice of mechanics,

chanics, will be able to apply them to many purpoſes of ingenious and uſeful practice. This article ſhall therefore be concluded by a few miſcellaneous remarks.

For the many uſes to which this kind of machinery may be adapted, it will ſeldom be found convenient that levers, which are the moſt eaſy means of communicating motion in many inſtances, ſhould be of equal length at both ſides of the fulcrum. It will, therefore, be neceſſary to meaſure each end, and to calculate, by common proportion, the ratio by which to adapt the diviſions of the wheels to the length of each arm from the centre or fulcrum. The lever, E, (*fig.* 26.) is an inſtance of this, for as its length from the joint to the extremity is more than that of the lever, F, to which it gives motion, the diviſions of the wheel, D, muſt be deeper than the others in the proportion by which the lever, E, exceeds the lever F.

It will alſo be apparent, that when the frame, H, moves upon its joint, the end of the lever, E, will be elevated or depreſſed, and thrown off the horizontal radius of the wheel B. As the range of motion is ſuppoſed to be ſmall, this may be ſufficiently counteracted by the intervention of a friction wheel between the lever, and the wheel B, or by many other plans.

In conſtructing the joints, it will alſo be neceſſary to pay very minute attention, that they may be well fitted, for a very ſmall deviation ſo near to the centre, will produce a great aberration where the lever touches the wheel. This may be corrected by guides of that deſcription, which are generally called *bridles* by mechanics. All the machinery conſtructed, for the ſake of curioſity and exhibition, depend entirely upon the principles already laid down. In ſome inſtances, it may be found more convenient to have the wheels faced like contrat wheels, and the cutting in that direction. In this caſe, the engine, already deſcribed, will work with ſufficient accuracy, by placing the rim of the wheel under the centre of the cutter, and adding another ſcrew, wheel, and ſcroll below, to ſtop the cutter when at a ſufficient depth. Or, if the axis of the wheels can be placed horizontally with the rim which is to be cut upon the ſame level with the cutter, the effect will be the ſame.

For the many purpoſes to which this machinery may be adapted, it is impoſſible to give preciſe rules. Every practical engineer, or mechanic, will know, that much muſt depend upon the knowledge and experience of the director. The directions given are the reſults of much practical experience, and the ingenious mechanic may apply them according to his own judgment and diſcretion.

Diagonal *Scale*. See Plotting *Scale*, and Scale.

DIAGORAS, in *Biography*, a follower of Democritus, was a native of the iſland of Melos; and having been ſold as a captive in his youth, he was redeemed by Democritus, and trained up in the ſtudy of philoſophy. He alſo cultivated polite learning, and diſtinguiſhed himſelf in the art of lyric poetry. However, his entire rejection of religion incurred the reproach of ſome of his contemporaries, and has tranſmitted his name to poſterity with infamy: and though Clemens Alexandrinus, and others, have endeavoured to vindicate his character by alleging that his only intention was to ridicule heathen ſuperſtitions, yet the general voice of antiquity has charged him with being the advocate of atheiſtical principles. As he belonged to the ſchool of Democritus, in which no other principles in nature beſides atoms and a vacuum were admitted, it is eaſy to conceive that he would reject the whole doctrine of a deity, as inconſiſtent with the ſyſtem which he had embraced. Indeed, ancient writers expreſsly aſſert, that when he ſaw a perjured perſon eſcape puniſhment, he publicly avowed his diſbelief of Providence, and from that time he deſpiſed and ridiculed the gods, and all religious ceremonies. He proceeded ſo far as to lay open the ſacred myſteries, and to diſſuade the people from ſubmitting to the rites of initiation. By theſe inſults which he offered to religion, he excited the hatred of the Athenians; and when he refuſed to obey a ſummons to appear in the courts of judicature, they iſſued a decree, which was inſcribed on a brazen column, propoſing the reward of a talent to any one who ſhould kill him, or two talents to any one who ſhould bring him alive before the judges. This happened in the 91ſt olympiad, B. C. 416. From that time Diagoras became a fugitive in Attica, and at laſt fled to Corinth, where he died. It is ſaid, that being on board a ſhip during a ſtorm, the terrified ſailors began to accuſe themſelves for having received into their ſhip a man ſo infamous for his impiety; upon which Diagoras pointed out to them other veſſels, which were near them on the ſea in equal danger, and aſked them whether they thought that each of theſe ſhips alſo carried a Diagoras; and that afterwards, when a friend, in order to convince him that the gods are not indifferent to human affairs, deſired him to obſerve how many conſecrated tablets were hung up in the temples in grateful acknowledgment of the eſcapes from the dangers of the ſea, he ſaid, in reply, "True; but here are no tablets of thoſe who have ſuffered ſhipwreck, and periſhed in the ſea." Theſe tales, however, are ſuſpected to be mere inventions; for ſimilar ſtories have been told of Diogenes, the Cynic, and others. Brucker's Hiſt. of Philoſ. by Enfield, vol. i.

DIAGRAM, from διαγραφω, *I deſcribe*, in *Geometry*, &c. a ſcheme for the explanation, or demonſtration, of any figure, or the properties thereto belonging.

Diagram, in the *Ancient Greek Muſic*, preſented to the eye the whole extent of a ſyſtem; which the moderns expreſs by *Gamut*, *Scale*, *Compaſs*; which ſee.

DIAGRAMMA, in *Ichthyology*, a ſpecies of *Perca*, which ſee.

DIAGRYDIUM, in *Pharmacy*, is ſcammony prepared for medicinal uſe. Scammony is a very powerful draſtic purgative, which is ſeldom given by itſelf, but always divided by triture with ſugar, gum arabic, or other mild ſubſtances, or with the gentler purgatives. The preparations which went under the term diagrydium in the older Pharmacopœias, but are now diſuſed, conſiſted of ſcammony, not merely mixed by triture with other ſubſtances, but prepared with more pains.

The *Diagrydium Sulphuratum* conſiſts of ſcammony in fine powder ſpread thinly on a paper full of pin holes, and held over the vapour of burning ſulphur, with frequent ſtirring, to prevent the ſcammony from ſcorching or clotting together. It was ſuppoſed to be dulcified, and its operation on the human body to be rendered milder and ſafer by this expoſure to the ſulphureous acid vapour. This preparation is now totally diſuſed.

The *Diagrydium cum Liqueritia* is thus prepared, according to the Pharmacopœia Helvetica: Boil two ounces of liquorice-root with three pints of water, till about half a pint is conſumed: then rub in a mortar ſix ounces of ſcammony in fine powder, with this liquorice decoction, and pour off the milky liquor from the blackiſh ſediment which remains. Evaporate this liquor with a heat not exceeding that of boiling water, firſt to the conſiſtence of an extract, then dry it further, till it becomes hard and pulverulent.

By this preparation the ſcammony loſes much of its nauſeous taſte, and its acrimony, but retains a very powerful purgative quality, when in the doſe of from five to twenty grains,

grains, and the liquorice gives it an agreeable taſte, which children do not refuſe.

This preparation, or a ſimilar one, in which the watery emulſion of ſcammony is employed, might, as we believe, be often employed with advantage, in preference to the compound powders, in which the ſcammony is ſimply rubbed with other ingredients. It is, however, entirely diſuſed in this country.

DIAH, or DIAT, a name given by the Arabs to the puniſhment of retaliation. By the Mahometan law, a brother, or the next relation of a murdered perſon, ought to take part againſt the murderer, and demand his blood in reparation for that which he has ſhed. Before the time of Mahomet, the Arabs had a cuſtom of putting a freeman of their priſoners to death, in lieu of every ſlave they loſt in battle, and a man for every woman that was killed. But Mahomet regulated the laws of repriſal; directing in the Alcoran, by the diat, that a freeman ſhould be required for a freeman, and a ſlave for a ſlave. The Turks, probably in conſequence of this law, formerly maſſacred almoſt all their priſoners of war, but they now content themſelves with enſlaving and ſelling them.

DIAHEXAPLA, from διὰ and ἑξαπλόος *ſix fold*, among *Farriers*, a drink made for horſes, denominated from the ſix ingredients it conſiſts of, *viz.* birth-wort, gentian root, juniper-berries, bay-berries, myrrh, and ivory-ſhavings. It is eſteemed a good ſtomachic, and cures bites of venomous beaſts, colds, conſumptions, &c.

DIAION, in the *Ancient Writers of Medicine*, the name of a compoſition made into the form of troches, of which violet-flowers were one of the principal ingredients. The compoſition is deſcribed at large by Myrepſus.

DIAL, or SUN-DIAL, an inſtrument ſerving to meaſure time by means of the ſhadow of the ſun.

The word is formed from *dies*, day, becauſe indicating the hour of the day. See HOUR.

The ancients alſo call it ſciathericum, from its doing it by the ſhadow.

DIAL is more accurately defined a draught, or deſcription, of certain lines on a plane, or ſurface of a body given, ſo contrived as that the ſhadow of a ſtyle, or ray of the ſun paſſed through a hole therein, ſhall touch certain points at certain hours.

The antiquity of dials is beyond doubt. Some attribute their invention to Anaximander, or his diſciple Anaximenes Mileſius, who flouriſhed in the ſixth century, B. C.: and others to Thales. Vitruvius mentions one made by the ancient Chaldee hiſtorian Beroſus, on a reclining plane, almoſt parallel to the equinoctial. Ariſtarchus Samius invented the hemiſpherical dial. And there were at the ſame time ſome ſpherical ones, with a needle for a gnomon. The diſcus of Ariſtarchus was an horizontal dial, with its limb raiſed up all around to prevent the ſhadow ſtretching too far.

But it was late before the Romans became acquainted with dials. The firſt ſun-dial at Rome was ſet up by Papirius Curſor, the Roman general, about the year of the city 461, B. C. 293; before which time, ſays Pliny, there is no mention of any account of time but by the ſun's riſing and ſetting: this firſt dial was ſet up at or near the temple of Quirinus, but it was imperfect; about thirty years after, as Pliny informs us, on the authority of Varro, M. Valerius Meſſala being conſul, brought from Catania in Sicily another dial, which he ſet up on a pillar near the roſtrum; but for want of its being made for that latitude, it could not point out the hours with exactneſs. They, however, made uſe of it ninety-nine years; till the cenſor Marcius Philippus ſet up another more accurate, and conſtructed for the latitude of Rome, near that of Valerius, In that interval dials became common at Rome, as appears from a fragment of Plautus, preſerved by Aulus Gellius, It is an hungry paraſite that ſpeaks.

"Ut illum dii perdant, qui primus *horas* reperit,
Quique adeo primus hîc ſtatuit ſolarium,
Qui mihi comminuit miſero articulatim *diem!*
Nam me puero uterus hic erat ſolarium,
Multò omnium iſtorum optumum et veriſſimum,
Ubi iſte monebat eſſe, niſi cum nihil erat.
Nunc etiam quod eſt, non eſt, niſi ſoli lubet.
Itaque adeo jam oppletum eſt oppidum ſolariis,
Major pars populi aridi reptant fame."

However, as a ſun-dial did not ſerve in cloudy weather, Scipio Naſica, five years after, remedied this defect, by introducing a method of dividing the night as well as the day into hours, by means of a water-machine, or *clepſydra* (which ſee); called by Pliny an *horologium*.

But there ſeem to have been dials among the Jews much earlier than any of theſe. Witneſs the dial of Ahaz, who began to reign four hundred years before Alexander, and within twelve years of the building of Rome, 741 years B. C.: mentioned by Iſaiah, chap. xxxviii. ver. 8.

The ancient Bramins ſeem to have been acquainted with this inſtrument, and to have applied it to aſtronomical purpoſes. The Chineſe and Egyptians were alſo acquainted with it at a very early period. Learned men have generally aſcribed the invention of it to the Babylonians, from whom the Jews derived it before the time of Ahaz. Herodotus traces the knowledge of the art of dialling among the Greeks to the ſame ſource.

The diverſity of ſun-dials ariſes from the different ſituation of the planes, and the different figure of the ſurfaces whereon they are deſcribed; whence they become denominated equinoctial, horizontal, vertical, polar, direct, erect, declining, inclining, reclining, cylindrical, &c. For the general principles of their conſtruction, ſee DIALLING. See alſo *Gnomonic* PROJECTION.

Dials are ſometimes diſtinguiſhed into primary and ſecondary.

DIALS, *primary*, are thoſe either drawn on the plane of the horizon, called horizontal dials; or, perpendicular thereto, on the planes either of the meridian, or prime vertical, called vertical dials: to which number are alſo uſually added, thoſe drawn on the polar and equinoctial planes, though neither horizontal, nor vertical.

DIAL, *equinoctial*, is that deſcribed on an equinoctial plane, or a plane repreſenting that of the equinoctial.

A plane oblique to the horizon, either hangs over towards it, and makes an acute angle with the plane of the horizon, or it falls off backwards from it, and makes an obtuſe angle therewith. This latter is called a reclining plane; which, if it recline back at an angle equal to the complement of the latitude of the place, then it lies in the plane of the equinoctial; and a dial drawn thereon, is denominated an equinoctial dial.

Equinoctial dials are uſually diſtinguiſhed into upper, which look towards the zenith; and lower, which reſpect the nadir.

Now, as the ſun only illumines the upper ſurface of an equinoctial plane, while he is in our hemiſphere, or on the northern ſide of the equator, an upper equinoctial dial will only ſhew the hour, during the ſpring and ſummer ſeaſon.

And again, as the ſun only illumines the lower ſurface of an equinoctial plane, while he is in the ſouthern hemiſphere,

or on the other ſide of the equator; a lower equinoctial dial will only ſhew the hour in autumn and winter.

To have an equinoctial dial, therefore, that ſhall ſerve all the year round, the upper and lower muſt be joined together; that is, it muſt be drawn on each ſide of the plane.

And, ſince the ſun ſhines on one ſide or on the other of an equinoctial plane the whole day, ſuch a dial will ſhew all the hours of an artificial day.

To deſcribe an equinoctial DIAL *geometrically*.—The equinoctial is the firſt, eaſieſt, and moſt natural, of all dials; but the neceſſity of drawing it double, prevents its being much in uſe. However, as its ſtructure ſhews the reaſon of the other kinds, and as it even furniſhes a good mechanical method of drawing all the other kinds of dials, it ſhall be here laid down.

Firſt, then, to deſcribe an upper equinoctial dial: from a centre C (*Plate* I. *Dialling fig.* 4.) deſcribe a circle A B D E, and by two diameters A D, and B E, interſecting each other at right angles, divide it into quadrants A B, B D, D E, and E A. Subdivide each quadrant into ſix equal parts, by the right-lines C I, C II, C III, &c. which lines will be hour lines. Through the centre C drive a ſtyle, or pin, perpendicular to the plane A B D E.

The dial thus deſcribed being raiſed ſo as to be in the plane of the equator, the line C XII, in the plane of the meridian, and the point A looking towards the ſouth, the ſhadow of the ſtyle will ſhew the hours both of the forenoon and afternoon.

For horary circles include arcs of the equator of fifteen degrees each; conſequently, the plane A B D E being ſuppoſed in the plane of the equator, the horary circles will likewiſe include arcs of 15 degrees of the circle A B D E. Wherefore, ſince the angles XII C XI, XI C X, X C IX, &c. are each here ſuppoſed 15 degrees, the lines C XII, C XI, C X, C IX, &c. are interſections of horary circles with the plane of the equinoctial.

Again, ſince the ſtyle paſſing through the centre C repreſents the axis of the world; its diſtance from the centre of the earth being inconſiderable, and it being the common diameter of the horary circles, its ſhadow will cover the hour-line C XII, when the ſun is in the meridian, or circle of 12 o'clock; C XI, when in the circle of 11 o'clock; C X, when in the circle of 10 o'clock, &c.

Secondly, to deſcribe a lower equinoctial dial: the method is the ſame as that for the upper dial, already deſcribed; except that no hour-lines are to be drawn beyond that of ſix o'clock.

Thirdly, to deſcribe an univerſal equinoctial dial: join two metal, or ivory planes, A B C D, and C D E F, (*fig.* 5.) ſo as to be moveable at the joint. On the upper ſurface of the plane A B C D, deſcribe an upper equinoctial dial, and upon the lower a lower, as already directed; and through the centre I drive a ſtyle. In the plane D E F C cut a box, and put a magnetic needle G therein; fit on the ſame plane a braſs quadrant nicely graduated, and paſſing through a hole cut in the plane A B C D. Now, ſince this may be ſo placed, by means of the needle, as that the line I 12 ſhall be in the plane of the meridian; and, by means of the quadrant, may be ſo raiſed, as that the angle B C F ſhall be equal to the elevation of the equator; it will ſerve as a dial in any part of the world. When the ſun is in the equator, theſe dials can be of no uſe.

The beſt univerſal dial is that of Mr. Pardie, of which the following deſcription is given by Mr. Ferguſon. This dial conſiſts of three principal parts; the firſt is called the horizontal plane A (*fig.* 6.) becauſe in practice it muſt be parallel to the horizon; in this plane is fixed an upright pin, which enters into the edge of the ſecond part B D, called the meridional plane, which is made of two pieces, the loweſt whereof, B, is called the quadrant, becauſe it contains a quarter of a circle divided into 90 degrees; in which part, near B, the pin enters. The other piece is a ſemicircle D, adjuſted to the quadrant, and turning in it by a groove, for raiſing or depreſſing the diameter E F of the ſemicircle, which diameter is called the axis of the inſtrument. The third piece is a circle G, divided on both ſides into 24 equal parts, which are the hours. This circle is put on the meridional plane, ſo that the axis E F may be perpendicular to the circle; and the point C be the common centre of the circle, ſemi-circle, and quadrant. The ſtraight edge of the ſemicircle is chamfered on both ſides to a ſharp edge, which paſſes through the centre of the circle. On one ſide of the chamfered part, the firſt ſix months of the year are laid down, according to the ſun's declination for their reſpective days, and on the other ſide the laſt ſix months. And againſt the days on which the ſun enters the ſigns, there are ſtraight lines drawn upon the ſemicircle, with the characters of the ſigns marked upon them. There is a black line drawn along the middle of the upright edge of the quadrant, over which hangs a thread H, with its plummet I, for levelling the inſtrument. From the 23d of September to the 20th of March, the upper ſurface of the circle muſt touch both the centre C of the ſemicircle, and the line of ♈ and ♎; and from the 20th of March to the 23d of September, the lower ſurface of the circle muſt touch that centre and line. In order to find the time of the day by this dial, it muſt be ſet on a level place in ſun-ſhine, and adjuſted by the levelling ſcrews *k* and *l*, till the plumb-line hangs over the black line upon the edge of the quadrant, and parallel to the ſaid edge; then move the ſemicircle in the quadrant, till the line of ♈ and ♎ (where the circle touches) comes to the latitude of the place in the quadrant; and turn the whole meridional plane B D, with its circle G, upon the horizontal plane A, till the edge of the ſhadow of the circle falls preciſely on the day of the month in the ſemicircle; and then the meridional plane will be due north and ſouth, the axis E F will be parallel to the axis of the world, and will caſt a ſhadow upon the true time of the day, among the hours in the circle, which is now in the plane of the equinoctial. The upper ſurface of the circle will ſerve from the 20th of March to the 23d of September; and the lower for the reſt of the year.

The months and ſigns are laid down on the ſemicircle in the following method. Draw the right line A C B (*fig.* 7.) equal to the diameter of the ſemicircle A D B, and croſs it in the middle at right angles with a line E C D, equal in length to A D B; then E C will be the radius of the circle F C G, which is the ſame as that of the ſemicircle. Upon E, as a centre, deſcribe the circle F C G, on which ſet off the arcs C *b* and C *i*, each equal to $23\frac{1}{2}$ degrees, and graduate them accordingly, for the ſun's declination. Then, laying the edge of a ruler over the centre E, and alſo over the ſun's declination for every fifth day of each month, as found in tables of declination, mark the points on the diameter A B of the ſemicircle from *a* to *g*, which are cut by the ruler; and here place the days of the months, anſwering to the ſun's declination. Set one foot of the compaſſes in C, and extending the other to *a* or *g*, deſcribe the ſemicircle *a b c d e f g*; divide this into ſix equal parts, and through the points of diviſion draw right lines parallel to C D, for the beginning of the ſines (of which one-half are on one ſide of the ſemicircle, and the other half

on the other) and ſet the characters of the ſigns to their proper lines. Ferguſon's Lectures, &c. Lect. 10.

DIAL, *Horizontal*, is that deſcribed on a horizontal plane, or a plane parallel to the horizon.

Since the ſun may illuminate an horizontal plane at all times of the year, while he is above the horizon; an horizontal dial may ſhew all the hours of the artificial day throughout the year: ſo that a more perfect dial than this kind cannot be required.

To deſcribe an horizontal DIAL *geometrically*.—Draw a meridian line A B (*fig.* 8.) on the given immoveable plane; or aſſume it at pleaſure, on a moveable one. See MERIDIAN *line*.

From a point taken at pleaſure, as C, erect a perpendicular C D, and make the angle C A D equal to the elevation of the pole. In D make another angle C D E, equal likewiſe to the elevation of the pole, and draw the right line D E, meeting A B in E. Then make E B equal to E D, and from the centre B, with the radius E B, deſcribe a quadrant, E B F, which divide into ſix equal parts. Through E draw the right line G H, cutting A B at right angles. From the centre B, through the ſeveral ſubdiviſions of the quadrant E F, draw right lines B *a*, B *b*, B *c*, B *d*, B H, meeting the line G H, in the points *a*, *b*, *c*, *d*, H. From E, upon the right line E G, ſet off the intervals E *a*, E *b*, &c. *viz.* E *a*, from E to *e*, E *b*, from E to *f*, E *c* from E to *g*, &c. from the centre A deſcribe a little circle, and applying a little ruler to A, and the little points of diviſion *a*, *b*, *c*, *d*, H, and *e*, *f*, *g*, *h*, G, draw the lines A XI, A X, A IX, A VIII, A VII, and A I, A II, A III, A IV, A V. Through A draw a right line VI, VI, perpendicular to A B. Continue the right line A VII, beyond the little circle to VII, A VIII to VIII, A V to V, and A IV to IV. Round the whole ſcheme draw a ſquare, circle, or oval figure. And laſtly, in A fix an index, making an angle D A C, with the meridian A B, equal to the elevation of the pole; or in C erect a perpendicular ſtyle equal to C D; or at A E fix a triangular plate A D E perpendicular to the plane of the dial. In this caſe, the lines, A XI, A X, A IX, &c. are the hour-lines of the forenoon; and A I, A II, A III, &c. thoſe of the afternoon; and the ſhadows of any of the gnomons, or ſtyles abovementioned, at the ſeveral hours, will fall on the reſpective hour-lines.

To deſcribe an horizontal DIAL *trigonometrically*.—In large dials, where the utmoſt accuracy is required, geometrical lines are beſt ſet aſide; and in lieu thereof, the lines of the dial are to be determined by trigonometrical calculation. M. Clapies, in the Memoires de l'Academie Royal des Sciences, anno 1707, has done the world good ſervice in this reſpect; having rendered the calculation of the hour-lines, which before had been operoſe enough, exceedingly eaſy and expeditious: his canons, or analogies, we ſhall lay down under the reſpective kinds of dials. And, firſt, for an horizontal dial; the elevation of the pole of the place being given to find the angles which the hour-lines make with the meridian in the centre of the dial.

The analogy, or canon, is this: as the whole ſine or radius is to the ſine of the elevation of the pole of the place, ſo is the tangent of the ſun's diſtance from the meridian, for the hour required, to the tangent of the angle required: that is, as the ſide AC (*fig.* 9.) is to DC, ſo is the tangent of FDC to the tangent FC, of the angle FAC. See TANGENT, &c.

To deſcribe an horizontal DIAL *by the terreſtrial globe*.—Let a common globe of twelve inches diameter, upon which are uſually drawn twenty-four meridian ſemi-circles, be elevated to the latitude of any given place, and turned about until any one of theſe meridians cuts the horizon in the north point, where the hour of XII is ſuppoſed to be marked; the reſt of the meridians will cut the horizon at the reſpective diſtances of all the other hours from XII. Let theſe points of diſtance be marked on the horizon, the globe be removed, and a flat board or plate, even with the ſurface of the horizon, put into its place, then ſtraight lines drawn from the centre of the board to theſe points will be the hour-lines of an horizontal dial for that latitude; and the gnomon will be in the ſituation of the axis of the globe, or make an angle with the plane of the dial equal to the latitude of the place. If the globe be elevated to the complement of the latitude of the given place, and you proceed as above, you will have a direct ſouth dial: obſerving, that the gnomon makes an angle with the dial plane equal to the co-latitude of the place, and that the hours on the dial muſt be ſet the contrary way to that on the horizontal. If the globe has more than twenty-four meridian ſemi-circles, the proceſs is ſomewhat different. Elevate the pole to the latitude $51°\frac{1}{2}$ N. *e. gr.* of London, and bring the firſt meridian, or that of London on the Engliſh globe, to the north: ſet the hour-index to the uppermoſt XII on the horary circle; then turn the globe weſtward, till the index points ſucceſſively to I, II, III, IV, V, and VI in the afternoon; or until 15, 30, 45, 60, 75, and 90 degrees of the equator paſs under the brazen meridian; and the firſt meridian will mark the following degrees on the horizon from the north towards the eaſt, *viz.* $11\frac{2}{3}$, $24\frac{1}{4}$, $38\frac{1}{12}$, $53\frac{1}{2}$, $71\frac{1}{15}$, and 90; which are the reſpective diſtances of the above hours from XII on the plane of the horizon.

In order to transfer theſe and the reſt of the hours to an horizontal plane, draw the parallel right lines *a c* and *b d* (*fig* 10.) upon that plane, at a diſtance equal to the thickneſs of the gnomon; and the ſpace between them will be the meridian or twelve o'clock line of the dial. At right angles to this meridian, draw *g h*, and on *a* and *b* as centres, with the ſame radius of any length, deſcribe the quadrants *g e*, and *f h*, and graduate them. The centre of the plane C, and the centres of theſe quadrants *a* and *b* are at a little diſtance from each other, in order to enlarge the hour diſtances about noon. Lay a ruler on the centre *b*, and on the ſeveral diſtances already found, *viz.* $11\frac{2}{3}$, $24\frac{1}{4}$, &c. in the quadrant *f h*, and draw the reſpective afternoon hour-lines to I, II, &c. As the ſun riſes about four in the morning, on the longeſt days in London, continue the hour-lines of III and V in the afternoon through the centre *b* to the oppoſite ſide of the dial. Then lay the ruler on the centre *a*, through the ſame diſtances, reſpectively in the quadrant *e g*, draw the forenoon hour-lines of XI, X, &c. and as the ſun does not ſet before eight in the evening on the longeſt days, continue the hour-lines of VII and VIII through the centre *a*, to the other ſide. Through $51\frac{1}{2}$ degrees of either quadrant from its centre draw the right line *a g*, which will be the hypotheneuſe or axis of the gnomon *a g i*; and from *g* let fall a perpendicular to the meridian *a i*; and a plate ſimilar to the triangle *a g i*, ſet up between *a c* and *b d*, will have its hypothenuſe *a g* parallel to the axis of the world, when the dial is truly ſet, and will caſt a ſhadow on the hour of the day. A line of cords will ſuperſede the neceſſity of graduating the quadrants. An erect ſouth dial (*Plate* II. *fig.* 15.) is conſtructed in the ſame manner, obſerving the rule already given with reſpect to the elevation of the pole, and of the gnomon, and the poſition of the hours. Ferguſon's Lect. lect. 10.

To deſcribe an horizontal DIAL *mechanically, by the dialling ſcales*.—Draw a double meridian line *a b*, *c d*, (*fig.* 11.) on the horizontal plane, and croſs it at right angles by the ſix o'clock

o'clock line *f e*; take the latitude of the place with the compaſſes, in the ſcale of latitudes, and ſet that extent from *c* to *e*, and from *a* to *f*, on the ſix o'clock line; then taking the whole ſix hours between the points of the compaſſes in the ſcale of hours; with that extent ſet one foot in the point *e*, and let the other foot fall where it will upon the meridian line *c d*, and at *d*. Do the ſame from *f* to *b*, and draw the right lines *e d* and *f b*, each of which will be equal in length to the whole ſcale of hours. When this is done, ſet one foot of the compaſſes in the beginning of the ſcale at XII, and extending the other to each hour on the ſcale, lay off theſe extents from *d* to *e* for the afternoon hours, and from *b* to *f* for thoſe of the forenoon; and thus the lines *d e* and *b f* will be divided in the ſame manner as the hour ſcale is divided, at 1, 2, 3, 4, 5, and 6; on which the quarters may alſo be laid down, if required. Then, laying a ruler on the point *c*, draw the firſt five hours in the afternoon from that point through the dots at the numeral figures 1, 2, 3, 4, 5, on the line *d e*, and continue the lines of IIII and V through the centre *c* to the other ſide of the dial for the like hours of the morning; then lay the ruler on the point *a*, and draw the laſt five hours in the forenoon through the dots 5, 4, 3, 2, 1, on the line *f b*; and continue the hour-lines of VII and VIII through the centre *a*, to the other ſide, for the like hours of the evening; ſet the hours to the reſpective lines, and make the gnomon in the manner already directed for the horizontal dial.

An erect ſouth dial may be made by taking the co-latitude of the place from the ſcale of latitudes, and proceeding in all reſpects for the hour-lines, as in the horizontal dial; only reverſing the hours, as in *fig.* 15. and making the angle of the ſtyle's height equal to the co-latitude.

An horizontal dial may be eaſily deſcribed with only a line of cords, or a graduated quadrant of a circle. With any opening of the compaſſes, as Z L, (*fig.* 12.) deſcribe the two ſemicircles L F *k* and L Q *k*, on the centres Z and *z*, where the ſix o'clock hour line croſſes the double meridian line, and divide each ſemicircle into twelve equal parts, beginning at L; then connect the diviſions, which are equidiſtant from L, by the parallel lines K M, I N, H O, G P, and F Q. Draw V Z for the hypothenuſe of the ſtyle, making the angle V Z E equal to the latitude of the place; and continue the line V Z to R. Draw the line R *r* parallel to the ſix o'clock line, and ſet off the diſtance *a* K from Z to Y, the diſtance *b* I from Z to X, *c* H from Z to W, *d* G from *z* to T, and *e* F from Z to S. Then draw the lines S *s*, T *t*, W *w*, X *x*, and Y *y* each parallel to R *r*. Set off the diſtance *y* Y from *a* to 11, and from *f* to 1; the diſtance *x* X, from *b* to 10, and from *g* to 2; *w* W from *c* to 9, and from *h* to 3; *t* T from *d* to 8, and from *i* to 4; *s* S from *e* to 7, and from *n* to 5. Then laying a ruler to the centre *z*, draw the forenoon hour-lines through the points 11, 10, 9, 8, 7: and laying it to the centre *z*, draw the afternoon lines through the points 1, 2, 3, 4, 5; continuing the forenoon lines of VII and VIII through Z, to the oppoſite ſide of the dial, for the like afternoon hours; and the afternoon lines IIII and V through *z* for the like morning hours. Set the hours to the lines, and erect the ſtyle, and the dial is complete. A ſouth dial may be conſtructed in the ſame manner, by drawing the line V Z to make an angle with the meridian Z L equal to the co-latitude of the place, &c. reverſing the hours, as in *fig.* 15. Ferguſon ubi ſupra.

DIAL, *Vertical*, is that drawn on the plane of a vertical circle. See VERTICAL.

Of theſe there are ſeveral varieties according to the vertical pitched upon. The verticals chiefly uſed, are the prime vertical, and the meridian; from which reſpectively ariſe, ſouth, north, eaſt and weſt dials.

Dials which reſpect the cardinal points of the horizon, are particularly called direct dials. See DIRECT.

If any other vertical be choſen, the dial is ſaid to decline. Farther, if the circle, whoſe plane is uſed, be perpendicular to the horizon, as is ſuppoſed to be the caſe in all thoſe now mentioned, the dials are particularly denominated erect. *E. gr.* erect ſouth, erect north, &c.

Otherwiſe the plane, being obliqûe to the horizon, they are ſaid either to incline or recline.

DIAL, *South*, or, more particularly an *erect direct ſouth* DIAL, is that deſcribed on the ſurface of the prime vertical circle looking towards the ſouth.

Since the ſun then illumines the plane of the prime vertical looking to the ſouth, when, in its progreſs, he paſſes from the prime vertical to the meridian, or returns back, from this to that; in which he is employed ſix hours before, and ſix after noon; a ſouth dial ſhews the hours from ſix in the morning to ſix at night

DIAL, *To draw a vertical ſouth*.—On the plane of the prime vertical looking ſouthwards, draw a meridian line A B (*fig.* 13.) and taking the interval A C, at pleaſure, for the magnitude of the future dial, in C erect a perpendicular, of an indefinite length C D, and making an angle C A D equal to the elevation of the equator; draw a right line A D, meeting the perpendicular C D in D. Then in the point D make the angle C D E likewiſe equal to the elevation of the equator, and draw the right line D E cutting the meridian in E. Through E draw the right line G H, cutting the meridian A B at right angles. Take E B equal to E D, and with this radius deſcribe a quadrant E F. The reſt is performed as in an horizontal dial, except that the hours of the afternoon are to be written on the right hand, and thoſe of the forenoon on the left; as may be conceived from the figure. Laſtly, in the point A fix an oblique ſtyle, in an angle equal to the elevation of the equator; or in C erect a perpendicular ſtyle, equal to C D; or, laſtly, a triangular plate A D E, upon A E, ſo as to be perpendicular to the plane of the dial.

Then will the ſhadow of any of theſe indexes touch the ſeveral hour-lines, at their reſpective hours.

DIAL, *North*, or *erect direct north* DIAL, is that deſcribed on the ſurface of the prime vertical looking northward.

Since the ſun only illumines this ſurface while he advances from the eaſt to the prime vertical, and proceeds from the ſame vertical to the weſt; and ſince he is in the prime vertical at ſix o'clock in the morning, and at ſix in the evening; a north dial ſhews the hours before ſix in the morning, and thoſe after ſix in the evening. And hence, as in autumn and winter-time, the ſun does not riſe before ſix, and ſets before ſix in the evening, a north dial is of no uſe all that time; but this being joined with a ſouth dial, ſupplies the defects thereof.

DIAL, *To deſcribe a vertical north*. Draw a meridian line E B, (*Plate* II. *fig.* 14.) and from A deſcribe a little circle at pleaſure. At A make the angle D A C equal to the elevation of the equator, and from the point C, taken at pleaſure, erect a perpendicular C D, meeting A D in D. Make another angle, C D E, likewiſe equal to the elevation of the equator, and draw likewiſe a line D E, meeting A E in E; then take I B equal to E D, and through I draw G H; cutting A B at right angles; and from the centre B, with the radius I B, deſcribe a quadrant, which divide into ſix equal parts: through the two extreme diviſions draw lines from the centre B, *viz.* B *h*, and B G, meeting G H in *h* and G, and make I *d* equal to I *h*, and I H equal

to

to I G; then applying a ruler to A and *h*, and G, and again to A and *d*, and H, draw the right lines A V, A IV, A VII, and A VIII. Laſtly, in A fix an oblique index A D, making an angle D A E, with a meridian line in the plane of the meridian, equal to the elevation of the equator; or the perpendicular index in C, equal to C D; or, inſtead of an index, a triangular plate E D A, on the meridian line E A, perpendicular to the plane of the dial.

Then will A IV, A V, A VI, be the hours of the forenoon; and A VI, A VII, and A VIII, thoſe of the afternoon; and accordingly will be pointed out by the ſhadow of the ſeveral indexes. Or thus, in a ſouth dial (*fig.* 13.) if the hour lines IV and V, as alſo VII and VIII, be continued beyond the line VI A VI; and the triangle A D E turned about its pole A, till A E fall directly on A XII produced; it is evident, a north dial is hereby had, only obſerving what has been ſaid about writing the hours.

To draw a vertical north or *ſouth* DIAL *trigonometrically.*

Theſe only differ from the horizontal dial, in that the angle C A B is equal to the complement of the elevation of the pole of the place; ſo that the ſame analogy ſerves as for the horizontal one; only making the ſecond term the complement of the elevation of the pole of the place.

For the method of deſcribing this dial by a globe, and by *dialling ſcales*, ſee *Horizontal* DIAL.

DIAL, *Eaſt*, or *erect direct eaſt* DIAL, is that drawn on the plane of the meridian, looking to the eaſt.

Since the ſun only illumines the plane of the meridian looking eaſtward, before noon, an eaſt dial can only ſhew the hours till twelve o'clock.

DIAL, *To deſcribe an eaſt.* On the eaſtern ſide of the plane of the meridian draw a right line A B (*Plate* II. *fig.* 16.) parallel to the horizon, and to this join A K, making with it an angle K A B, equal to the elevation of the equator: then, with the radius D E, deſcribe a circle, and through the centre D draw E C perpendicular to A K, by which means the circle will be divided into four quadrants. Each of theſe quadrants ſubdivide into ſix equal parts. And from the centre D through the ſeveral diviſions draw the right lines D IV, D V, D VI, D VII, D VIII, D IX, D X, D XI. Laſtly, in D erect a ſtyle equal to the radius D E, perpendicular to the plane; or, on two little pieces perpendicularly fixed in E C, and equal to the ſame radius D E, fit an iron rod, parallel to E C.

Thus will each index at the ſeveral hours project a ſhadow to the reſpective hour-lines IV IV, V V, VI VI, &c.

DIAL, *Weſt*, or *erect direct weſt* DIAL, is that deſcribed on the weſtern ſide of the meridian.

As the ſun only illumines that ſide of the plane of the meridian looking to the weſt after noon, a weſt dial can only ſhew the hours from noon to night.

This, therefore, joined with an eaſt dial, ſhews all hours of the day.

DIAL, *To draw a weſt.* The conſtruction is perfectly the ſame as that of an eaſt dial, only that its ſituation is inverted, and the hours are written accordingly.

DIAL, *Polar*, is that deſcribed on a plane paſſing through the poles of the world, and the eaſt and weſt points of the horizon. It is of two kinds, the firſt looking up towards the zenith, and called upper; the latter down to the nadir, called lower.

The polar dial, therefore, is inclined to the horizon in an angle equal to the elevation of the pole.

Since the polar plane P O Q S (*fig.* 17.) paſſes through the eaſt and weſt points O and S, a quadrant of the equator is intercepted between it and the meridian; conſequently the upper ſurface is illumined by the ſun from ſix in the morning to ſix at night; and the lower from the ſun's riſe to ſix in the morning, and from ſix in the evening to ſun-ſet. A lower polar dial, therefore, ſhews the hour of the morning from ſun-riſe to ſix o'clock, and that of the evening, from ſix to ſun-ſet; and an upper, the hours from ſix in the morning to ſix in the evening.

DIAL, *To draw an upper polar.* Draw a right line A B (*fig.* 18.) parallel to the horizon; and if the plane be immoveable, find the meridian line C E. Divide C E into two equal parts, and through C draw a right line F G parallel to A B. Then from the centre D, with the interval D E, deſcribe a quadrant, which divide into ſix equal parts; and from the ſame centre D, through the ſeveral points of diviſion, draw right lines, D I, D II, D III, D IV, D V, and the intervals E I, E II, E III, E IV, E V, ſet off the contrary way, *viz.* E XI, X, IX, VIII, and VII. From the points V, IV, III, II, I, &c. raiſe perpendiculars meeting the line F G in the correſpondent points. Laſtly, in D erect a perpendicular ſtyle equal to D E, or on two equal pieces, E and C, fix a croſs iron rod.

Then will XII XII, I I, II II, III III, &c. be hour-lines, to be pointed out at the proper times by the ſhadow of the indices.

DIAL, *an upper polar*, only differs in ſituation, and the manner of writing the hours, from eaſt and weſt dials, joined together in the line of ſix o'clock.

DIAL, *a lower polar*, is had by putting out the hours of the forenoon, IX, X, and XI, and thoſe of the afternoon, I, II, and III, with the noon-hour XII, itſelf; and only leaving the hours VII and VIII of the morning, and IV and V in the evening.

To make three DIALS *on three different planes, ſo that they may all ſhew the time of the day by one gnomon.*—On the flat board A B C (*fig.* 19.) deſcribe an horizontal dial, with its gnomon, F G H, the edge of the ſhadow of which ſhews the time of the day. To this horizontal board join the upright board E D C, touching the edge G H of the gnomon: then making the top of the gnomon at G the centre of the vertical ſouth dial, deſcribe it on the board E D C. Beſides, on a circular plate I K deſcribe an equinoctial dial, and by a ſlit *c d* in the XII o'clock line, from the edge to the centre, put it on the gnomon F G, as far as the ſlit will admit. The ſame gnomon will ſhew the ſame hour on each of thoſe dials.

To draw all the primary DIALS *on the ſame block or poſt.*—1. Let the plane A B C D, (*fig.* 20.) in the proper poſition of the block, be ſuppoſed horizontal; and thereon deſcribe a horizontal dial. See *Horizontal* DIAL.

2. Draw the right lines E M and F L parallel to D C, which, accordingly, in the proper poſition of the block, will be parallel to the horizon: then let the plane B N M C make an angle with E M, equal to the elevation of the pole C M E; and thereon deſcribe an upper polar dial.

3. Let the oppoſite plane, A D E, make with E M an angle D E M, equal to the elevation of the equator; and on this draw an upper equinoctial dial.

4. Let the plane, K L H I, make with F L an angle H L F, equal to the elevation of the equator; and on this inſcribe a lower equinoctial dial.

5. Let the oppoſite plane, F G, make with F L an angle G F L, equal to the elevation of the pole; and here draw a lower polar dial.

6. Let the plane M N K L, and the oppoſite one E F, be perpendicular to F L; and on that draw a ſouth dial, and on this a north dial.

7. On the plane E M L F deſcribe a weſt dial; and on the oppoſite plane an eaſt dial.

If,

If, then, the block be ſo placed, as that the plane M N K L looks to the ſouth, and the plane of the meridian biſect it in the line of 12 o'clock in the horizontal dial A B C D, and ſouth dial M N K L, all the hours of the day will be indicated by ſeveral planes at once.

DIALS, *Secondary*, are all thoſe drawn on the planes of other circles, beſides the horizon, prime vertical, equinoctial, and polar circles; or thoſe which either decline, incline, recline, or deincline.

DIALS, *Declining*, are erect or vertical dials, which decline from any of the cardinal points; or they are ſuch as cut either the plane of the prime vertical, or of the horizon, at oblique angles.

The uſe of declining dials is very frequent; as the walls of houſes, whereon dials are uſually drawn, commonly deviate from the cardinal points.

Of declining dials there are ſeveral kinds, which are denominated from the cardinal points; which they ſeem moſt to reſpect, but from which they have a real declination: decliners from the ſouth and from the north, as a ſouth-eaſt decliner, a ſouth-weſt decliner, a north-eaſt decliner, and a north-weſt decliner, and even decliners from the zenith.

To draw a vertical declining DIAL *trigonometrically.*

1. The declination of the plane, and the elevation of the pole of the place, being given; to find the angle formed in the centre of the dial, by the meridian and ſubſtyle.

Canon. As the whole ſine is to the tangent of the complement of the height of the pole of the place G F (*fig.* 21.) ſo is the ſine of the angle of the declination of the plane G F D, to the tangent G D, of the angle required G A D.

2. The declination of the plane being given, and the elevation of the pole of the place, to find the angle formed in the centre of a vertical declining dial, by the ſubſtyle and axis.

Canon. As the whole ſine is to the ſine of the complement of the elevation of the pole G F; ſo is the ſine of the complement of the declination of the plane D G F, to the ſide D F, the ſine of the angle D A B required.

3. The declination of the plane, and the elevation of the pole, given; to find the difference of longitudes, that is, the arc of the equator, comprehended between the meridian of the place and the meridian of the plane.

Canon. As the whole ſine is to the ſine of the height of the pole of the place, ſo is the tangent of the complement of the declination of the plane, to the tangent of the complement of the difference of longitudes.

4. The angle of the difference of longitudes, and that of the axis with the ſubſtyle, being given; to find the angles formed in the centre of a vertical declining dial, between the ſubſtyle and hour-lines.

This problem admits of three caſes; for the hour-lines, whoſe angles are ſought, may be either, 1. Between the meridian and ſubſtyle; or, 2. Beyond the ſubſtyle; or, 3. On that ſide of the meridian where the ſubſtyle is not. In the two firſt caſes, the difference is to be taken between the ſun's diſtance from the meridian that hour, and the angle of the difference of longitudes found by the laſt problem; and in the third caſe, the ſum of thoſe two angles is to be taken, and the following canon uſed.

Canon. As the whole ſine is to the ſine of the angle between the axis and ſubſtyle, ſo is the tangent of the difference of the ſun's diſtance from the meridian, and the difference of longitudes, or of the ſum of thoſe two angles, to the tangent of the angle required.

5. The angle formed by the ſubſtyle, with the hour-lines, and that of the ſubſtyle with the meridian, given; to find the angles formed between the meridian and hour-lines in the centre of vertical declining dials.

1. The angles of the hour-lines between the meridian and ſubſtyle are found by ſubtracting the angle formed by the ſubſtyle with the hour-line from the angle formed by the ſubſtyle with the meridian.

2. The angles beyond the ſubſtyle, and on the ſide oppoſite to that of the meridian, are found by adding thoſe two angles.

3. Thoſe on the other ſide of the meridian are found by taking their difference.

To deſcribe a vertical DIAL, *declining from the ſouth to the eaſt* or *weſt geometrically.*—Find the declination of the plane, as already taught, under the article DECLINATOR. Then draw upon a paper an horizontal dial, ſuppoſing the line of contingency of the horizontal with the equinoctial plane to be G H (*fig.* 22.) through the point E, wherein the meridian line A E cuts the ſame, draw a right line I K, making with G H an angle H E K, equal to the declination of the given plane. Thus, as G H repreſents the interſection of the prime vertical with the horizon, I K will be the interſection of the declining plane and the horizon; whence we alſo conceive, that the part I E muſt be raiſed above G E, in caſe the given plane decline to the weſt; or it muſt be depreſſed below the ſame G E, in caſe it decline to the eaſt. Draw a right line parallel to the horizon on the given plane, or wall, to anſwer to I K; and aſſuming a point therein anſwering to E, ſet off from the right line I K on the paper the ſeveral horary diſtances E 1, E 2, E 3, &c. Then from the point E erect a perpendicular E C, equal to the diſtance of the centre of the horizontal dial, from its line of contingency. Draw lines thence to the ſeveral points of the hour-lines E 1, E 2, E 3, &c. let fall a perpendicular A D, from the centre of the horizontal dial A, to the line of contingency I K, and transfer the diſtance E D, from the point E upon the wall: then will C D be the ſubſtylar line.

Wherefore, joining A D and D C at right angles, the hypothenuſe A C will be an oblique index, to be faſtened on the wall in the point C, according to the angle D C A.

To conſtruct a vertical DIAL, *declining from the ſouth towards the eaſt or weſt, by the globe.*—Elevate the pole to the latitude of the place, and ſcrew the quadrant of altitude to the zenith. If the dial declines towards the eaſt, count the degrees of declination in the horizon from the eaſt point towards the north, and bring the lower end of the quadrant to that degree of declination, at which the reckoning ends. Then bring any meridian (*e. gr.* the firſt meridian) directly under the graduated edge of the upper part of the brazen meridian, and ſet the hour index to XII at noon. Turn the globe eaſtward on its axis, the quadrant of altitude being kept to the degree of declination in the horizon, and obſerve the degrees cut by the firſt meridian in the quadrant of altitude, counted from the zenith, as the hour index comes to XI, X, IX, &c. in the forenoon; and the degrees, then cut in the quadrant by the firſt meridian, are the reſpective diſtances of the forenoon hours from XII on the plane of the dial. For the afternoon hours, turn the quadrant of altitude round the zenith till it comes to the degree in the horizon oppoſite to that where it was placed before, or as far from the weſt point towards the ſouth as it was at firſt from the eaſt towards the north; and turn the globe weſtward on its axis, till the firſt meridian comes to the brazen meridian, and the hour index to XII; then turning the globe weſtward to the afternoon hours I, II, III, &c. the firſt meridian will cut the quadrant of altitude in the reſpective number of degrees from the zenith, that each of theſe hours is from XII on the dial; and the limit of this dial will be determined by the hour-

index,

index, when the firſt meridian goes off the quadrant at the horizon, both in the forenoon and afternoon. Lay down theſe hour-diſtances on the dial plane, either by dividing a ſemicircle into two quadrants, beginning at the hour line of XII, or by the line of cords, as directed under *horizontal* DIAL. As the ſubſtyle makes an angle with the meridian line in this kind of dials, falling among the forenoon hour-lines in an eaſt decliner, and among thoſe in the afternoon in a dial declining towards the weſt, its diſtance may be found in the former, by counting the degrees of the declination of the dial in the horizon from the eaſt point towards the north, and bringing the lower end of the quadrant of altitude to that degree of declination where the reckoning ends; then turn the globe till the firſt meridian cuts the horizon in the like number of degrees, counted from the ſouth point toward the eaſt; and the quadrant and firſt meridian will croſs one another at right angles, and the number of degrees of the quadrant, intercepted between the firſt meridian and the zenith, is equal to the diſtance of the ſubſtyle line from the 12 o'clock line; and the number of degrees of the firſt meridian, which are intercepted between the quadrant and the north pole, is equal to the elevation of the ſtyle above the plane of the dial. If the dial declines weſtward from the ſouth, count that declination from the eaſt point of the horizon towards the ſouth, and bring the quadrant of altitude to the degree in the horizon at which the reckoning ends; both for finding the forenoon hours, and diſtance of the ſubſtyle from the meridian; and for the afternoon hours bring the quadrant to the oppoſite degree in the horizon, as far from the weſt towards the north; and then proceed as above. The north dial declining eaſt or weſt by the ſame number of degrees may be eaſily had from the former, by only extending the hour-lines, ſtyle, and ſubſtyle, quite through the centre; for thus the ſouth-eaſt decliner will produce the north-weſt decliner, and the ſouth-weſt decliner the north-eaſt decliner. Ferguſon, lib. cit.

To draw a vertical DIAL, *declining from the north towards the eaſt and weſt.*—Take the declination of the planes, as already taught; then, as north dials are only ſouth dials inverted, draw a vertical dial declining from the ſouth, and invert it in ſuch a manner, as that the centre C looks to the horizon, and the point E to the zenith; and the hours on the right hand ſet off towards the left, and contrary-wiſe, omitting all hour-lines, which in ſuch a plane cannot be ſhewn.

For the practice, the beſt way is, after drawing a ſouth decliner upon paper, to prick the ſeveral points thereof through with a pin; then applying the face of the paper to the wall, the back ſide thereof will ſhew you all the points neceſſary for the north declining dial.

DIALS, *Inclined*, are thoſe drawn on planes not erect, but inclining, or leaning forward towards the ſouth, or ſouthern ſide of the horizon, in an angle, either greater or leſs than the equinoctial plane.

Such an inclined plane may be conceived by ſuppoſing one part of the plane of the equator lifted up towards the zenith, and the other depreſſed towards the nadir; and thus to revolve upon a line drawn from the eaſt to the weſt point of the horizon.

DIAL, *To draw an inclined.* 1. The inclination of the plane as DC (*fig.* 23.) being found by a declinator, as taught under DECLINATOR; if it fall between the equinoctial plane C E, and the vertical one C B, in ſuch manner as that the angle of inclination D C A is greater than the elevation of the equator E C A; on the upper ſide draw a north dial, and on the lower a ſouth dial, to an elevation of the equator, which is equal to the aggregate of the elevation of the equator of the given place, and the complement of the inclination to a quadrant.

2. If the inclined plane C F fall between the horizontal one C A, and the equinoctial C E, ſo as that the angle of inclination F C A, is leſs than the elevation of the equator E C A, deſcribe an horizontal dial to an elevation of the pole, equal to the aggregate of the elevation of the pole of the given place, and the inclination of the plane. Dials, thus inclined, are drawn after the ſame manner as primary dials; except, that the index in the former caſe muſt be fitted under the angle A D C; and in the latter, under the angle D F C; and that the diſtance of the centre of the dial from the line of contingency, in the former caſe, is D C, and in the latter F C.

DIALS, *Reclining*, are thoſe drawn on planes not erect, but reclined, or leaning backwards from the zenith towards the north, in an angle greater or leſs than the polar plane. A reclined plane may be conceived by ſuppoſing one part of the polar plane raiſed towards the zenith, and the other depreſſed towards the nadir; and thus revolving about a line drawn from eaſt to weſt. To find the reclination of a plane, ſee RECLINATION.

DIAL, *To draw a reclining.* 1. If the reclined plane H C fall between the vertical plane B C, and the polar plane I C, ſo as that the angle of reclination B C H is leſs than the diſtance of the pole from the zenith B C I, deſcribe two vertical ſouth and north dials to an elevation of the equator equal to the difference between the elevation of the equator of the given place, and the angle of reclination. 2. If the reclined plane, as K C, fall between the polar plane I C, and the horizontal one C L, ſo as that the angle of reclination B C K is greater than the diſtance of the pole from the zenith I C B, deſcribe an horizontal dial thereon to an elevation of the pole, equal to the difference between the angle of reclination, and the elevation of the equator of the given place.

To draw inclining and reclining DIALS *trigonometrically.*—The inclination and reclination of the plane, and the elevation of the pole, being known, to find the angles made in the centre of an inclining or reclining dial, by the meridian and hour lines.

Such dial is properly an horizontal dial, for a latitude equal to the particular elevation of the pole on the plane of the dial. Its angles, therefore, are found by the canon laid down for horizontal dials.

As to the elevation of the pole on the dial plane, it is thus found: the plane being inclined, either its inclination is greater than the elevation of the pole of the place, or leſs; or it is equal thereto. In the two firſt caſes, for upper ſouth, or lower north dials, the particular elevation of the pole on the plane is had by taking the difference between the elevation of the pole of the place, and the inclination of the plane; and in the latter caſe, the dial is a polar dial, wherein the hour-lines will be parallel, by reaſon that the plane being placed on the axis of the world, neither of the poles can be repreſented thereon.

For upper north, and lower ſouth dials. 1. If the inclination be greater than the complement of the elevation, the complement of the inclination muſt be added to the complement of the elevation. 2. If it be leſs, the inclination muſt be added to the elevation. 3. If it be equal, the dial will be an equinoctial dial, wherein the angles at the centre will be equal to the ſun's diſtance from the meridian.

DIALS, *Deinclined*, are thoſe which both decline and incline, or recline. See DECLINERS.

The uſe of inclined, reclined, and eſpecially deinclined

dials, is very rare; the geometrical and trigonometrical conſtruction of theſe laſt, therefore, as being ſomewhat intricate, we here chooſe to omit, and refer ſuch as may have a fancy for ſuch a dial, to an univerſal mechanical method of drawing all kinds of dials here ſubjoined

An eaſy method of deſcribing a DIAL *on any kind of plane, by means of an equinoctial* DIAL, *or circle* —Suppoſe, *e. gr.* a dial required on an horizontal plane: if the plane be immoveable as A B D C (*Plate* II. *fig.* 24.) find a meridian line G F; or, if moveable, aſſume the meridian at pleaſure. Then, by means of the triangle E K F, whoſe baſe is applied on the meridian line, raiſe the equinoctial dial H, till the index G I becomes parallel to the axis of the world (which is had if the angle K E F be equal to the elevation of the pole), and the 12 o'clock line on the dial hang over the meridian line of the plane, or the baſe of the triangle. If then, in the night-time, a lighted candle be ſucceſſively applied to the axis G I, ſo as the ſhadow of the index, or ſtyle G I, fall upon one hour-line after another; the ſame ſhade will mark out the ſeveral hour-lines on the plane A B C D.

Noting the points, therefore, on the ſhadow, draw lines through them to G; then an index being fixed in G, according to the angle I G F, its ſhadow will point out the ſeveral hours by the light of the ſun.

If a dial were required on a vertical plane, having raiſed the equinoctial circle, as above directed, puſh forward the index G I, till the tip thereof, I, touch the plane.

If the plane be inclined to the horizon, the elevation of the pole ſhould be formed on the ſame; and the angle of the triangle K E F ſhould be made equal thereto.

See a new method of conſtructing ſun-dials, for any given latitude, without the aſſiſtance of dialling ſcales, or logarithmic calculations, by Mr. Ferguſon, in the Phil. Tranſ. vol. lvii. for 1767, art. 36, and in his Select Exerciſes, p. 95.

Note. Beſide the ſeveral ſpecies of dials above-mentioned, with are ſaid to be with centres, there are others, called dials without centres. See CENTER *of a Dial.*

DIALS *without centres*, are thoſe whoſe hour-lines do really converge, but ſo ſlowly, that the centre towards which they converge cannot be expreſſed in the given plane.

DIALS, *Horizontal, without centres*, are to be made for places, the elevation of whoſe pole is either very ſmall, or very great.

DIALS, *Vertical, without centres*, are for places, the elevation of whoſe pole is very great.

DIALS, *For the furniture of.* See FURNITURE.

DIAL, *Quadrantal.* See *Horodictical* QUADRANT.

DIAL, *Reflecting.* See REFLECTING *Dial.*

DIAL, *Cylindric*, is repreſented in *Plate* III. *fig.* 27. This dial may be delineated on paper, and then paſted round a cylinder of wood, and it will ſhew the time of the day, the ſun's place in the ecliptic, and his altitude at any time of obſervation. Draw the right line *a* A B (*fig.* 28.) parallel to the top of the paper, and with any opening of the compaſſes on the centre *a* deſcribe the quadrant A E, and graduate it. Draw the right line A C at right angles to *a* A B, and touching the quadrant A E at the point A. From the centre *a* draw right lines through as many degrees of the quadrant as are equal to the ſun's altitude at noon, on the longeſt day of the year, at the place for which the dial is to ſerve; which altitude at London is nearly 62 degrees; continue theſe right lines till they meet the tangent line A C; and from the points of concourſe, draw ſtraight lines acroſs the paper, parallel to the firſt right line A B, and theſe will be the parallels of the ſun's altitude in whole degrees, from ſun-riſe to ſun-ſet, on all the days of the year. Theſe parallels of altitude muſt be drawn out to the right line B D, which muſt be parallel to A C, and as far from it as is equal to the intended circumference of the cylinder on which the paper is to be paſted. Divide the ſpace between the right lines A C and B D, at top and bottom, into twelve equal parts, for the twelve ſigns of the ecliptic; and from one mark to the oppoſite one, draw right lines parallel to A C and B D; and place the characters of the twelve ſigns in the twelve ſpaces at the bottom, beginning with ♑ Capricorn, and ending with ♓ Piſces. Theſe ſpaces ſhould likewiſe be divided by parallel lines into halves and quarters. At the top of the dial make a ſcale of the months and days of the year, ſo that the days may ſtand over the ſun's place, found in an Ephemeris, for each of them in the ſigns of the ecliptic. Compute the ſun's altitude for every hour, in the latitude of your place, or take it from a table, when he is in the beginning, middle, and end of each ſign of the ecliptic; and in the upright parallel lines, at the beginning and middle of each ſign, make marks for theſe altitudes among the horizontal parallels, reckoning downward in the order of the numeral figures at the right-hand, anſwering to the like diviſions of the quadrant at the left. Through theſe marks draw the curve hour-lines, and ſet the hours to them, as in the figure, reckoning the forenoon hours downward, and the afternoon hours upward. The ſun's altitude may alſo be taken and laid down for the half hours and quarters. Then cut off the paper at the left-hand on which the quadrant was drawn, cloſe by the right line A C, and all the paper at the right-hand, cloſe by the right line B D, and cut it alſo cloſe by the top and bottom horizontal lines, and it will be fit for paſting round the cylinder. This cylinder, (*fig.* 27.) is hollow for holding the ſtyle D E, when it is not uſed. The ſtyle muſt ſtand out, perpendicular to the ſide of the cylinder, juſt over the right line A B, (*fig.* 28.) where the parallels of altitude begin, and its length, or diſtance of the point *e* from the cylinder, muſt be equal to the radius *a* A of the quadrant A E (*fig.* 28.) When this dial is uſed, the horizontal foot B C is placed on a level table, or hung by the ring F, where the ſun ſhines, and the horizontal top A D, which is made moveable, is turned till the ſtyle ſtands juſt over the day of the month. Then the cylinder is turned round, till the ſhadow of the ſtyle falls upon it, parallel to the upright lines which divide the ſigns; or till the ſhadow is parallel to a ſuppoſed axis in the middle of the cylinder; and then the point, or loweſt end of the ſhadow, will fall upon the time of the day, as it is before or after noon, among the curve hour-lines, and will ſhew the ſun's altitude at that time among the croſs parallels of altitude, encompaſſing round the cylinder; and it will alſo ſhew in what ſign of the ecliptic the ſun is at that time, and the degree may be nearly eſtimated by the eye. Ferguſon.

When the ſun is in the equinoctial, and has no declination, his altitude may be eaſily found by the following proportion. As radius is to the coſine of the latitude, ſo is the coſine of the hour from noon to the ſine of the altitude: but if he has north or ſouth declination, ſay, as radius is to the ſine of the declination, ſo is the ſine of the latitude to the ſine of the ſun's altitude at ſix o'clock. For the ſun's altitude at other hours the two following proportions muſt be uſed, *viz.* 1. As the coſine of the hour from the meridian to radius, ſo is the tangent of the latitude to the tangent of a fourth arc, from which the declination is to be ſubtracted, when north, and to which it is to be added, when ſouth, for a fifth arc. The ſupplement of the ſun's declination, added to the fourth arc, muſt be uſed for this fifth arc, when they exceed a quadrant, in finding the altitudes before and after ſix.

2. As the ſine of the fourth arc is to the coſine of the fifth arc, ſo is the ſine of the latitude of the place to the ſign of the altitude for the given hour and declination.

The altitude in the middle of the ſign may either be had by taking the arithmetic mean between the next greateſt and leaſt, or by computation in the manner above directed. Leybourn's Dialling, Tract vi. p. 23, &c.

To find the altitude by the globe, ſee GLOBE.

DIAL, *Portable on a card*, is repreſented in *fig.* 29. and may be eaſily conſtructed. Draw the occult line AB (*fig.* 30.) parallel to the top of the card, and croſs it at right angles with the ſix o'clock line ECD: then upon C, as a centre, with the radius CA, deſcribe the ſemicircle AEL, and divide it into twelve equal parts, beginning at A, as A *r*, A *s*, &c. and from theſe points of diviſion draw the hour-lines *r*, *s*, *t*, *u*, *v*, *w*, and *x*, all parallel to the ſix o'clock line EC. If each part of the ſemicircle be ſubdivided into four equal parts, they will give the half hour lines and quarters, as in *fig.* 29. Draw the right lines ASD *o*, making the angle SAB equal to the latitude of the place. Upon the centre A deſcribe the arc RST, and ſet off upon it the arcs SR and ST, each equal to $23\frac{1}{2}$ degrees, for the ſun's greateſt declination, and divide them into $23\frac{1}{2}$ equal parts, as in *fig.* 29. Through the interſection D of the lines ECD and AD *o* draw the right line FDG at right angles to AD *o*. Lay a ruler to the points A and R, and draw the line ARF through $23\frac{1}{2}$ degrees of ſouth declination in the arc SR; and then laying the ruler to the points A and T, draw the line ATG through $23\frac{1}{2}$ degrees of north declination in the arc ST; ſo ſhall the lines ARF and ATG cut the line FDG in the proper length for the ſcale of months. Upon the centre D, with the radius DF, deſcribe the ſemicircle F *o* G, which divide into ſix equal parts F *m*, *m n*, *n o*, &c. and from theſe points of diviſion draw the right lines *m h*, *n i*, *p k*, and *q l*, each parallel to *o* D. Then ſetting one foot of the compaſſes in the point F, extend the other to A, and deſcribe the arc A *z* H for the tropic of ♑; with the ſame extent, ſetting one foot in G, deſcribe the arc AEO for the tropic of ♋. Next ſetting one foot in the point *h*, and extending the other to A, deſcribe the arc ACI for the beginnings of the ſigns ♒ and ♐; and with the ſame extent, ſetting one foot in the point *l*, deſcribe the arc AN for the beginnings of the ſigns ♊ and ♌. Set one foot in the point *i*, and having extended the other to A, deſcribe the arc AK for the beginnings of the ſigns ♓ and ♍; and with the ſame extent ſet one foot in *k*, and deſcribe the arc AM for the beginnings of the ſigns ♉ and ♎. Then ſetting one foot in the point D, and extending the other to A; deſcribe the curve AL for the beginnings of ♈ and ♑; and the ſigns will be finiſhed. This done, lay a ruler from the point A over the ſun's declination in the arc RST, found by a table, for every fifth day of the year; and where the ruler cuts the line FDG, make marks, and place the days of the months right againſt theſe marks, as in *fig.* 29. Laſtly, draw the ſhadow line PQ parallel to the occult line AB; make the gnomon, and ſet the hours to their reſpective lines, as *fig.* 29. and the dial will be finiſhed.

The lines *a d*, *a b*, and *b c*, of the gnomon, muſt be cut quite through the card; and as the end *a b* of the gnomon is raiſed occaſionally above the plane of the dial, it turns upon the uncut line *c d* as on an hinge. The dotted line AB muſt be ſlit quite through the card, and the thread C muſt be put through the ſlit, and have a knot tied behind, to keep it from being eaſily drawn out. On the other end of this thread is a ſmall plummet D, and on the middle of it a ſmall bead for ſhewing the hour of the day.

To rectify this dial; ſet the thread in the ſlit right againſt the day of the month, and ſtretch the thread from the day of the month over the angular point, where the curve lines meet at XII; then ſhift the bead to that point on the thread; and the dial will be rectified.

To find the hour of the day; raiſe the gnomon, and hold the edge of the dial next the gnomon towards the ſun, ſo that the uppermoſt edge of the ſhadow of the gnomon may juſt cover the ſhadow-line; and the bead then playing freely on the face of the dial, by the weight of the plummet, will ſhew the time of the day among the hour-lines, in the forenoon or afternoon.

To find the time of ſun-riſing and ſetting; move the thread among the hour-lines, until it either covers ſome one of them, or lies parallel betwixt any two; and then it will cut the time of ſun-riſing among the forenoon hours, and of ſun-ſetting among the afternoon hours for that day of the year to which the thread is ſet in the ſcale of months.

To find the ſun's declination; ſtretch the thread from the day of the month over the angular point at XII, and it will cut the ſun's declination, as it is north or ſouth, for that day, in the proper ſcale.

To find on what day the ſun enters the ſigns; when the bead, as above rectified, moves along any of the curve lines which have the ſigns of the zodiac marked upon them, the ſun enters thoſe ſigns on the days pointed out by the thread in the ſcale of months.

DIAL, *Univerſal, on a plain croſs*, is repreſented by *fig.* 31, and is moveable on a joint, C, for elevating it to any given latitude on the quadrant C *o* 90, as it ſtands upon the horizontal board A. The arms of the croſs ſtand at right angles to the middle part; and the top of it, from *a* to *n*, is of equal length with any of the arms *n e* or *m k*.

This dial is rectified, by ſetting the middle line *t u* to the latitude of the place on the quadrant, the board A level, and the point N northward by the needle; thus, the plane of the croſs will be parallel to the plane of the equator. Then from III o'clock in the morning till VI, the upper edge, *k l*, of the arm, *i o*, will caſt a ſhadow on the time of the day on the ſide of the arm *e m*; from VI till IX, the lower edge, *i*, of the arm, *i o*, will caſt a ſhadow on the hours, on the ſide *o q*. From IX in the morning to XII at noon, the edge, *a b*, of the top part, *a n*, will caſt a ſhadow on the hours on the arm *n e f*; from XII to III in the afternoon, the edge *c d* of the top part will caſt a ſhadow on the hours of the arm *k l m*; from III to VI in the evening, the edge *g h* will caſt a ſhadow on the hours on the part *p q*; and from VI till IX, the ſhadow of the edge, *e f*, will ſhew the time on the top part *a n*. The breadth of each part, *a b*, *e f*, &c. muſt be ſo great, as never to let the ſhadow fall quite without the part or arm on which the hours are marked, when the ſun is at his greateſt declination from the equator.

To determine the breadth of the ſides of the arms which contain the hours, ſo as to be in juſt proportion to their length; make an angle, ABC, (*fig.* 32.) of $23\frac{1}{2}$ degrees, which is equal to the ſun's greateſt declination; and ſuppoſe the length of each arm, from the ſide of the long middle part, and alſo the length of the top part above the arms, to be equal to B *d*. Then, as the edges of the ſhadow, from each of the arms, will be parallel to B *e*, making an angle of $23\frac{1}{2}$ degrees with the ſide B *d*, of the arm, when the ſun's declination is $23\frac{1}{2}^{\circ}$: it is plain, that if the length of the arm be B *d*, the leaſt breadth that it can have, to keep the edge B *e* of the ſhadow, B *e g d*, from going off the ſide of the arm, *d e*, before it comes to the end of it, *e d*, muſt be equal to *e d* or *d* B. But, in order to keep the ſhadow within the quarter diviſions of the hours, when

it comes near the end of the arm, the breadth of it ſhould be ſtill greater, ſo as to be almoſt doubled, on account of the diſtance between the tips of the arms.

The hours may be placed on the arms, by laying down the croſs, *abcd* (*fig.* 33.) on a ſheet of paper; and with a black lead pencil, held cloſe to it, drawing its ſhape and ſize on the paper. Then take the length *ae* in the compaſſes, and with one foot in the corner *a*, deſcribe with the other the quadrant *ef*. Divide this arc into ſix equal parts, and through the points of diviſion draw right lines *ag*, *ah*, &c. continuing three of them to the arm *ce*, which are all that can fall upon it; and they will meet the arm in thoſe points through which the lines that divide the hours from each other, as in *fig.* 31, are to be drawn right acroſs it. Divide each arm, for the three hours contained in it, in the ſame manner; and ſet the hours to their proper places, on the ſides of the arms as they are marked in *fig.* 33. Each of the hour ſpaces ſhould be divided into four equal parts, for the half hours and quarters, in the quadrant *ef*; and right lines ſhould be drawn through theſe diviſion-marks in the quadrant, to the arms of the croſs, in order to determine the places thereon, where the ſubdiviſions of the hours muſt be marked.

This is a very ſimple kind of univerſal dial; it is eaſily made, and has a pretty uncommon appearance in a garden. Ferguſon.

Dials, *Refracted*, are ſuch as ſhew the hour by means of ſome refracting tranſparent fluid.

If a pin or ſtick be ſet up, or any point be aſſigned in a concave bowl or diſh for the centre of the dial, let an horizontal dial be applied over the ſame, aſſigning the meridian line on the edges of the bowl, and marking out the reſt of the hour-lines alſo on the edges of the bowl; take away the horizontal dial, and elevate a ſtring or thread from the end of the ſaid pin over the meridian line, as much as is the latitude or elevation of the pole of the place: then, by bringing the thread to caſt a ſhadow on any hour point formerly marked out on the edges of the bowl, by a candle or the like, that ſhade in the bowl is the true hour-line; and if the bowl be full of water, &c. when this is done, it will never ſhew the true hour by the ſhadow of the top of the pin but when it is filled again with the ſame liquor.

Dial, *Ring*, is a kind of dial, uſually ſmall and portable, conſiſting of a braſs ring or rim, ſeldom exceeding two inches in diameter, and one-third of an inch in breadth. In a point of this rim there is a hole, through which the ſunbeams being received, make a lucid ſpeck on the concavity of the oppoſite ſemicircle, which gives the hour of the day in the diviſions marked therein.

Theſe diviſions are made by deſcribing a circle, (*Plate* IV. *fig.* 34.) to repreſent the ring, and drawing an horizontal chord E F; with this as radius deſcribe the quadrant F D, and graduate it; and through the ſeveral degrees which mark the ſun's altitude for every hour at the time of the equinox, draw lines from E to the oppoſite part of the circle, and there ſet the correſponding figures. Thus the XII o'clock line will paſs through 38° 38′, the co-latitude of the place; and the XI and I line through 36° 56′; the X and II through 32° 36′; the IX and III through 26° 5′; the VIII and IV through 18° 8′; and the VII and V through 9° 17′. This may be eaſily calculated by the globe.

But it only holds good about the times of the equinox. To have the dial perform throughout the whole year, the hole is made moveable, and ſigns of the zodiac, or the days of the month, are marked on the convex ſide of the ring, by taking, *e.g.* E T and E *t* (*fig.* 34) on each ſide of E equal to double the ſun's declination when he enters any particular ſign, as Taurus or Piſces; and there marking the character of the ſaid ſign, or correſponding month, and ſo for all the others; and by means of theſe the dial is rectified for the time. It is evident, from a view of the figure, that E XII ♉ is = F E XI I = the altitude of the ſun in the equinox; but T XII E is equal to the ſun's declination in Taurus, becauſe it is an angle in the circumference ſtanding upon an arc, which is double the declination; and therefore T XII ♉ is equal to the meridian altitude when the ſun enters Taurus; and a ray paſſing through the hole at T will mark the XII o'clock hour of that day; but this dial will not point out the other hours exactly: becauſe T III *d* exceeds E III *d*, the equinoctial hour by the angle of declination; and ſo of the reſt. Some have contrived to remedy this inconvenience, by making the concave ſurface of the ring wider, and deſcribing upon it ſeven circles, the middle one to repreſent the equinoctial, and the extremes the tropics; and in theſe circles they have marked the forenoon and afternoon hours from a table of altitudes.

To uſe it, put the moveable hole to the day of the month, or the degree of the zodiac the ſun is in; then ſuſpending it by the little ring, turn it towards the ſun, till his rays, as before, point out the hour among the diviſions on the inſide.

Univerſal or *aſtronomical Ring*-Dial, is a ring-dial, which ſerves to find the hour of the day in any part of the earth; whereas the former is confined to a certain latitude. Its figure ſee repreſented in *Plate* IV. *fig.* 35.

It conſiſts of two rings or flat circles, from two to ſix inches in diameter, and their breadth, &c. proportionable. The outward ring, A, repreſents the meridian of any place you are at, and contains two diviſions of 90° each, diametrically oppoſite to one another, ſerving the one from the equator to the north, the other to the ſouth pole. The inner ring repreſents the equator, and turns exactly within the outer, by means of two pivots in each ring at the hour XII.

Acroſs the two circles goes a thin reglet or bridge, with a curſor C, that ſlides along the middle of the bridge. In the curſor is a little hole for the ſun to ſhine through. The middle of this bridge is conceived as the axis of the world, and the extremities as the poles; and on the one ſide are drawn the ſigns of the zodiac, and on the other the days of the month. On the edge of the meridian ſlides a piece, to which is fitted a ring to ſuſpend the inſtrument by.

In this dial, the diviſions on the axis are the tangents of the angles of the ſun's declination, adapted to the ſemidiameter of the equator as radius, and placed on either ſide of the centre: but inſtead of laying them down from a line of tangents, a ſcale of equal parts may be made, whereof 1000 ſhould anſwer exactly to the length of the ſemi-axis, from the centre to the inſide of the equinoctial ring; and then 434 of theſe parts may be laid down toward each end from the centre, which would limit all diviſions on the axis, becauſe 434 is the natural tangent of 23° 29′. And thus, by a nonius fixed to the ſliding-piece, and taking the ſun's declination from an ephemeris, and the tangent of that declination from the table of natural tangents, the ſlider might be always ſet true within two minutes of a degree. And this ſcale of 434 equal parts might be placed right againſt the $23\frac{1}{2}°$ of the ſun's declination, on the axis, inſtead of the ſun's place, which is there of little uſe. For then the ſlider might be ſet in the uſual way, to the day of the month, for common uſe; but to the natural tangent of the declination, when great accuracy is required.

Uſe of the Univerſal Ring-Dial.—Place the line *a* (on

ſideration, the court are of opinion that the matter ſuggeſted is not a good and ſufficient ground to ſtop the proceedings below. Thus careful has the law been, in compelling the inferior courts to do ample and ſpeedy juſtice; in preventing them from tranſgreſſing their due bounds; and in allowing them the undiſturbed cognizance of ſuch cauſes as by right, founded on the uſage of the kingdom or act of parliament, do properly belong to their juriſdiction. Blackſt. Com. vol. iii.

CONSUMMATE ESTATE. See TENANT *by curteſy*.

CONSUMMATION, the end, period, or completion, of any work.—Thus, we ſay, the conſummation of all things: meaning the end of the world. By the incarnation, all the prophecies are to be conſummated.

Conſummation of marriage denotes the laſt act of marriage, which makes its accompliſhment.

CONSUMPTION, in *Medicine*, popularly named a *decline*, is a generic term, occaſionally applied to different diſeaſes, the moſt obvious ſymptoms of which are a gradual decline of the ſtrength and functions of the body, and a diminution of its bulk, in conſequence of the decreaſe or conſumption, as it were, of the fat and muſcular parts. From whatever cauſe, therefore, the nutrition of the body is impeded, conſumption will be the conſequence. The nutrition of the body may be impeded either by ſome great internal diſeaſe, which diſturbs the functions, eſpecially that of digeſtion; or by deficiency of nutriment; or by great evacuations or diſcharges of blood, or fluids ſecreted from the blood. Theſe conſiderations have led noſologiſts to treat of conſumption under three diviſions or genera, with the titles of *Phthiſis*, *Tabes*, and *Atrophia*: the two firſt being produced by internal organic diſeaſes; the laſt by the deficiency, or the abſtraction, or corruption, of nutritious matter.

1. *Phthiſis*, Φθίσις, ſignifying *conſumption* in general, is confined to that ſpecies which originates from diſeaſe of the lungs: this form of conſumption being the moſt frequent and fatal. It is defined "emaciation, with hectic fever, cough, and commonly with purulent expectoration." The emaciation is occaſioned by the diſturbance in the function of digeſtion, which the daily fever produces; by the impediment to the function of reſpiration, which the diſeaſed lungs are unable to carry on; and by the great diſcharges by expectoration, ſweating, or diarrhœa, which latter frequently alternate with each other.

2. *Tabes*, which, in the Latin language, is ſynonymous with *phthiſis* in the Greek, has been arbitrarily reſtricted by noſologiſts to that form of conſumption, which is not accompanied by cough. It is defined, "emaciation, with hectic fever." Any local diſeaſe of long continuance, ſuch as abſceſſes, ulcers, &c. which excites a hectic fever, may become the origin of a *tabes*. But the moſt frequent occurrence of tabes is obſerved in ſcrofulous habits, the ſcrofula being always ſlow in its progreſs: and one of the moſt common varieties of tabes ariſes, where ſcrofula attacks the glands of the meſentery. In this caſe emaciation is produced, not only by the diſturbance of functions, and the ſweats of the hectic fever, but by the phyſical impediment to the nutrition of the body, occaſioned by the morbid condition of the meſenteric glands, through which the chyle cannot paſs, in order to enter the thoracic duct, and thence to be poured into the blood-veſſels.

3. *Atrophia*, derived from the primitive particle α, and τρέφω, *nutrio*, implying *defect of nouriſhment*, has been adopted to denote the ſimple emaciation and loſs of ſtrength, which is not accompanied with hectic fever, nor originates from any organic diſeaſe; but depends altogether on the privation, corruption, or abſtraction, of that which would otherwiſe ſupport the ſtrength of the body. It is defined, "emaciation, without fever." Hence atrophia occurs in thoſe who have ſuffered great evacuations, as from ſalivation, hæmorrhage, ſweat, leucorrhœa, &c.; in thoſe from whom nutriment is abſtracted in undue proportion to their ſtrength and digeſtive powers, as in nurſes ſuckling ſtout children, or continuing them at the breaſt too long; and in thoſe whoſe nutriment is corrupted, as the ſalt proviſions, which excite ſcurvy.

For a view of the nature and requiſite treatment of the different kinds of conſumption, ſee the following articles: TABES *Meſenterica* (or Meſenteric Conſumption), and ATROPHY. Savage's Noſol. Method. Claſs x. ord. 1. Cullen's Synopſis Noſol. Claſs i. ord. 4. and Claſs iii. ord. 1.

CONSUMPTION, *Pulmonary*, the *phthiſis pulmonalis* of medical writers, from φθίω, or φθέω, *corrumpo*, *conſumo*, a diſtreſſing and very fatal diſeaſe, diſtinguiſhed by the occurrence of a frequent cough, with expectoration of puriform matter, hectic fever, emaciation, and debility; to which, in the latter ſtages, colliquative ſweats, often alternating with diarrhœa, ſupervene.

In this diſeaſe the number, degree, and progreſs, of the ſymptoms are extremely various, in different caſes. It uſually commences in an inſidious manner, with a ſlight and ſhort cough, which is often little remarked by thoſe affected with it, but ſoon becomes habitual; or with an occaſional cough, which is more ſevere. At the ſame time, the breathing becomes eaſily hurried by any bodily motion, the patient grows leaner, and becomes languid and indolent. In this ſtate he ſometimes continues for a year, or even for two years, without making any complaint, excepting that he is affected by cold more readily than uſual, which frequently increaſes his cough, and produces catarrh. This, however, is ſometimes relieved, is ſuppoſed to have ariſen from cold alone, and therefore gives no alarm either to the patient or to his friends, nor leads them to take any precaution. But upon ſome occaſion of catching cold, as we commonly ſpeak, the cough becomes more conſiderable; is particularly troubleſome, when the patient lies down at night, and in this ſtate continues longer than is uſual in the caſe of a ſimple catarrh. This may more particularly attract attention, if the increaſe and continuance of cough occur during the ſummer ſeaſon.

The cough, in many inſtances, continues for a long time dry, or without any expectoration; frequently, however, it is accompanied, from the firſt, with an expectoration of a blackiſh or blueiſh mucus, or of tough phlegm; the expectoration being generally moſt conſiderable in the morning, in conſequence of the accumulation of the matter during ſleep. This matter becomes by degrees more copious, more viſcid, and more opake; at length of a yellow or greeniſh colour, and of a purulent appearance, ſometimes ſtreaked with blood. As theſe changes take place, and the cough increaſes, the breathing at the ſame time becomes more difficult, and the emaciation and weakneſs go on alſo increaſing. In the female, as the diſeaſe advances, and ſometimes early in its progreſs, the menſes ceaſe to flow; and this circumſtance, although doubtleſs an effect, the ſex themſelves are generally diſpoſed to believe to be the ſole or principal cauſe of the diſeaſe. During this progreſs ſome pain is commonly felt in the thorax, at firſt under the ſternum, eſpecially, or almoſt ſolely, on the occaſion of coughing: but very often there is a pain in one ſide, ſometimes dull and oppreſſive, ſometimes ſharp and ſhooting, and ſuch as to prevent the perſon from lying eaſy upon that ſide. Even

when

DIAL, *Siderial.* See NOCTURNAL.

DIAL, *Tide.* See TIDE-*Dial.*

DIAL-*Bird*, in *Ornithology*. the *dial grekle* of Latham, and *Saularis Gracula* of Gmelin, which ſee.

DIAL-*Plate*, is the face of an inſtrument which ſhews the time or hour of the day either by means of a moving hand or index, or by the ſhadow of a gnomon that falls upon it; hence we hear of clock-dials, watch-dials, and ſun-dials.

The clock makers have alſo given the name of dials to a particular ſort of time-pieces; *viz* ſuch as are generally uſed in kitchens, ſhops, &c. They are eight day pendulum movements, which do not ſtrike, but only ſhew the hours and minutes.

The dial-plates of clocks and watches are almoſt univerſally divided into twelve hours, which are denoted by Roman numerals, and each of thoſe hours is ſubdivided into five minutes, ſo as to divide the whole circumference into ſixty equal parts or minutes. Inſtead of Roman numerals, the hours of ſome clocks and watches are often indicated by the common numerical or Arabic figures; and ſometimes they are even fancifully indicated by the letters of ſome particular word, or name. We have ſometimes, though ſeldom, ſeen the dial-plate of a clock divided into 24 hours, or twice 12; and in them the hour hand of courſe goes round once only in 24 hours. In certain particular time-pieces, the hours on the dial plate are diſpoſed in a ſpiral manner; ſo that four or ſix of them fill up the whole circumference, and the reſt are marked under thoſe, and nearer to the centre (as in Dr. Franklin's clock, and others); the hour hand then going round the whole circumference in leſs time than 12 hours. See the next article.

DIAL-*Plate* of a *Clock* or *Watch*, called alſo the *face*, is that fixed plate which contains the divided circles of hours, minutes, and ſeconds, pointed to by the reſpective hands, and which is pinned to the frame by the dial-pillars. This plate, in the ancient machines, was made of braſs, engraved into various devices, and ſilvered, ſometimes only partially; but the modern makers prefer enamel to ſilvering, and that either real or imitative, according to the price intended to be charged for the workmanſhip. The maker's name is alſo uſually put on ſome conſpicuous part of the dial-plate; and if the machine is contrived ſo as to have the repeating mechaniſm, the days of the month, the moon's age, the days of the week, or ſun's place in the ecliptic, &c. The divided circles containing theſe, or ſome of theſe, are introduced, and perforations to ſhew the diviſions of other ſmaller plates, revolving within or behind the principal plate, are frequently ſuperadded.

DIAL-*Work* of a *Clock* or *Watch*, properly ſpeaking, is that work which relates to the dial-plate, hands, dial-pillars, and ſmall revolving plates, that are ſometimes calculated to perform their revolutions in certain given periods of time; but, becauſe the reſpective periods, and relative ſituations of the moving parts depend on the motion-work, or wheel-work, contained between the dial-plate and the frame, the term dial-work may be ſaid to include alſo the motion-work, on which depend the figure, dimenſions, and circles of indication on the dial-plate, as well as the number of indicating hands. In the infancy of clock-work, there was but one hand, indicating the hours and ſubdiviſions of the hour, and inſerted on the protruding arbor of the fuſee, or barrel, made to revolve in twelve hours; but when the motion-work was introduced to ſubdivide the hour more ſenſibly into minute portions, it was found that any modified period of time might be repreſented by wheel-work, borrowing its motion from the going-part of the machine, without materially altering its rate of going, particularly when the motions produced are ſlow. Hence aroſe the practice of repreſenting planetary phenomena, and of introducing various devices, either for uſe or ornament, which enhance the value, or rather the price of many clocks and watches, of which a great portion of the mechaniſm is ſuperfluous, and frequently renders the rate of their going unſteady. It might be conſidered as unneceſſary now, that clocks and watches are in every perſon's poſſeſſion, to give a minute detail of the circles and hands on an ordinary dial-plate; but as many of our readers may wiſh to know the connection between the hour and minute hands, in regard to the mechaniſm behind the dial, we beg leave to refer to *Plate* XII. of *Horology*, and to the deſcriptions of an eight-days' portable clock with repeating mechaniſm, under the head CLOCK, where the requiſite information has been already given. The ſame deſcription is equally applicable to the dial-work of an ordinary watch: and when the ſeconds are ſhewn by a long hand moving from the centre of the face, the calliper is ſo laid down, that a cannon wheel revolves in a minute, (over a bridge that has got a tube ſurrounding the interior cannon wheel of the hours) in conſequence of its connection with a ſimilar wheel on the arbor of the wheel that uſually carries the ſeconds' hand out of the centre. The dials ſhewn in *Plate* XXIII. already deſcribed, as contrived by Dr. Franklin and Mr. Ferguſon, have no motion-work, but ſimply the hands, or revolving plates attached to the arbors of the going part of the clock, which we mention here with a reference to the word CLOCK, leſt the reader ſhould conſult our preſent article for them in vain. We have alſo deſcribed the dial-work of Enderlin's equation clock, as ſeen in *Plate* XXIV., in *fig.* 2, of which is ſeen a dial with the hours, minutes, and ſeconds out of the centre, together with other appendages, with the account of which the curious reader will be intereſted in the article already referred to. We have, however, reſerved for our preſent article three or four different ſpecimens of dial-work, that have not been before deſcribed, and that, we truſt, will therefore be acceptable to the public.

Plate XXXI. of *Horology* preſents two figures, the firſt of which exhibits the motion-work under the dial of a clock, that indicates the days of the week and month, together with that of the moon's age, and at the ſame time repreſents the moon's phaſes; and *fig.* 2, is the repreſentation of the correſponding dial, with the parts ſeen through the perforated parts. In *fig.* 1, the letter *a* is placed on the wheel of 72 teeth that revolves, as in common, in twelve hours, by means of its connection with the cannon pinion of ſix leaves; to this wheel is attached another ſmaller one, *b*, of 30 teeth, or any other convenient number, which actuates a third of ſixty, *i. e.* double its number, in 24 hours exactly, but in a contrary direction, which is ſeen denoted by *c*. This wheel of 60 teeth has two pins projecting from its plane, ſeen near the ſmall letter *c*, one of which only we will regard at preſent. The pin nearer to the extremity of the wheel comes in contact with a tooth *d*, projecting from the edge of the vertical bar *de*, once in every 24 hours, and lifts this bar, which is kept in a true vertical poſition by a little bridge, *e*, below, and a pin within the ſlit at the ſuperior end, which pin is held by a ſmall cock, over the plane of the twelve-hours' wheel: the conſequence of this diurnal lifting is, that a jointed tooth, *f*, attached to the ſaid vertical bar, takes one of the ſeven points of the ſtar *g*, and turns the ſtar till the heel of the ſautoir, *h*, paſſes the point of the ſtar at preſent reſting againſt its leg, and puſhes it one-ſeventh part round by the action of the ſmall ſpring, *i*; the vertical bar then deſcends by its weight, its tooth being clear of the pin in wheel *c*, till its jointed tooth, *f*, falls on the next ſucceeding point of the ſtar, on which

which it would reſt if it had no joint; but the weight of the bar is ſufficient to make this tooth, *f*, turn on its pivot or joint, till it has paſſed the ſaid point of the ſtar, after which the little ſpring underneath the back part of the tooth reſtores its horizontal poſition, below the point of the ſtar that is to be caught the ſucceeding day; and in this way, the ſtar is made to revolve in ſeven days, by as many ſudden daily leaps, and it preſents an attached plate with ſeven days of the week on it, as they occur, to an aperture at one of the inferior corners of the dial where the word *Monday* is now ſeen exhibited in *fig.* 2.

Again, the inner pin, projecting from the plane of the 24 hour wheel *c*, meeting with the curved triangular part of K*l*, which is a piece of metal moveable on a ſtud at the point *l*, ſlides along it, and at the ſame time raiſes it upwards, while the jointed tooth, attached to its oppoſite end, is depreſſed, ſo as to urge a tooth of the ſerrated rim, kept in its place by the three rollers, *m*, *n*, and *a*; preſently, however, the pin of *c* comes in contact with the extreme corner of K, that points downwards, and paſſing it, allows it to return from its elevated poſition, till its tail-piece meets with a pin in the ſmall cock below *l*; but its weight is ſufficient to make it fall with velocity enough to bend the joint of the tooth that impels the rim; therefore, a ſpring is attached to the ſmall cock, and acts on the back portion of the tail-piece, to give the requiſite force in the fall. The tooth here has alſo a re-acting ſpring, like the jointed tooth *f*, and finds its horizontal poſition by means of its action on the back part of the tooth ſeen reſting on a pin, that prevents its falling beyond the horizontal line. Now, as the rim in queſtion has 31 teeth on its interior edge, one of which is moved thus every day, it is evident, that if its plane be divided into 31 equal ſpaces, they will be ſo many day ſpaces, to indicate the day of the month, as ſeen through ſome convenient opening in the dial, which, for the ſake of uniformity, may be juſt above the point VI of the dial, as we have given it in *fig.* 2. This rim, it will be obſerved, will require a monthly adjuſtment by hand, that No. 1. may begin with the firſt day of each month. We have, indeed, ſeen a contrivance, different from Enderlin's already deſcribed, for making the month-plate adjuſt itſelf at the end of each month, in a clock made by a Scotchman of the name of Smith, of Pittenween, in Fifeſhire, and exhibited in 1808, for public inſpection, at No. 27, Leiceſter ſquare; but as ſome part of the value of the ſuperb machine conſiſted of this contrivance, which was ſhewn us in confidence, we feel not at liberty to make it public, without the proprietor's previous conſent. On the rim we have been deſcribing is a pin, which takes hold of one of the 12 points of the ſtar *p*, the action of which is preciſely the ſame as that of ſtar *g*, already deſcribed; on a plate connected with this ſtar, and revolving with it in 12 months, are the months deſignated and ſhewn through another opening at the inferior corner of the dial, in *fig.* 2. oppoſite to that of the days. The two engraved plates of the days and months are deſignated in *fig.* 1. by dotted circles only. The wheel *a*, which we have ſaid revolves in the ſpace of 12 hours, has alſo its pin for the moon's wheel, independently of its pin for making the clock ſtrike, which pin takes the interior end of the lever *q*, that carries a third jointed tooth, in every reſpect like thoſe deſcribed, ſo far as relates to the action; and whenever the interior end of the ſaid lever is depreſſed by its pin of wheel 72, which happens once in each 12 hours, the jointed tooth puſhes a tooth of the moon's wheel, which conſiſt of 118; hence two of theſe are actuated in the ſpace of each 24 hours, and the ſautoir *r* keeps this wheel ſteadily to its place after each puſh; thus the moon's wheel, denoted by *s*, revolves once in 59 days, or in a period ſomewhat more than two lunations. On the plane of the moon's wheel, which is ſolid plate, are painted two moons diametrically oppoſite each other, which appear to put on all the natural aſpects ſucceſſively, by the help of a triangular aperture in the dial-plate, two ſides of which figure are ſemi-circles to the radius of the moon's curvature, as repreſented in *fig.* 2, which is the ſituation for Monday, July 4th 1808, when the moon's age is 12. The edge of the moon's plate, beyond the painted part, is figured twice over into 29½ ſpaces, which are the ſpaces of the moon's age ſeen through the curved opening over the moon herſelf, at any given time. The hour and minute hands, and alſo the circles of the dial, being of the ordinary kind, require no explanation. The practical objections to the dial-work here deſcribed, are, that the regularity of the maintaining power is greatly interrupted by the hourly, daily, and monthly oppoſing forces to be overcome by only ſhort intervals of action, particularly when the weights and ſprings that conſtitute the oppoſing forces are conſiderable, which they muſt be to anſwer their purpoſe; ſecondly, the means uſed, though they profeſs to be ſimple, in as much as they avoid ſolar and lunar calculations for appropriate wheel-work, yet are actually more complex and expenſive than proper trains would be, without re-acting ſprings, and other mechanical appendages; and, laſtly, manual adjuſtment of the monthly plate is requiſite many times within the year, as well as occaſionally a rectification of the moon's age neceſſary, when the deficiency of 44 minutes 3 ſeconds amounts to an entire day. We might here proceed to ſhew how Ferguſon, Jenkins, and others, have obviated the objections we have ſtated, by introducing the reſpective calculations of trains into their aſtronomical, or rather planetary, clocks; but as the accounts of them have been publiſhed by the authors themſelves, in Ferguſon's Mechanical Exerciſes, and in a deſcription of ſeveral aſtronomical and geographical clocks, by Henry Jenkins, London, 1778, we will give the dial-work of a ſmall portable clock, contrived by the writer of the preſent article in the year 1800, which indicates all the periods of the preceding clock, with the addition of the moon's place in the ecliptic, and of her nodes, latitude, and apogee, in a ſimple and unobjectionable manner, and which is the only clock that has been made of the kind.

Fig. 1. of *Plate* XXXII. of *Horology*, ſhews the motion-work of the little clock alluded to, and *fig.* 2. its dial, forming together what may be called its dial-wheel. Partly on account of the ſimplicity of the wheel-work, which ſtands in place of the ordinary motion-work, and partly for the ſake of novelty, in the mode of reading the time indicated, the hours and minutes are both pointed to, at all times, by the ſame hand; the minutes are indicated in the outer large circle of Arabic figures, and the hours in the inner one, or circle of Roman numerals, which, at firſt ſight, will appear a paradox, but when the reader is told that the inner circle moves as well as the common hand, the wonder will ceaſe; their reſpective velocities are 60 : 55; ſo that ſuppoſing the point XII and the hand to ſtart together from the point 60, in the fixed circle, when the hand has gone round, which it does in an hour, and indicates minutes on the fixed circle, the hour-plate has its point XII at 55, and its point I at 60, under the end of the hand; and at every ſucceſſive revolution of the hand, the hour-plate falls back the twelfth part of a circle, and in the ſame proportion for any ſmaller quantity, by which means both the hour and minute, at any period of the day, are both immediately under their common hand. At preſent the indication is half paſt one o'clock, as ſeen in *fig.* 2; and puzzling as this mode may ſeem at firſt, it is actually more ſimple for a child to learn, than the ordinary mode by two hands, where one may be miſtaken for the other; the only

objection

objection is, that the hour cannot ſo well be known at a diſtance. The moveable plate being ſmall, and equally poiſed, by being circular, conſtitutes no obſtacle to free motion. The relative velocities are thus effected: the hand is carried by the arbor of the hour-wheel in the uſual way, and a tubed or cannon pinion, *a*, of 22 leaves, is put on tight, in the common manner, which gives its velocity to a pinion, *b*, of a ſimilar number, and this pinion being made long and conical, turns on a ſtud in the front of the frame, and actuates a third pinion of 24, concentric with the firſt and covering it, round the tube of the little bridge that takes off the friction as uſual, ſo that, as the velocities of the firſt and third pinions are to each other inverſely as their reſpective numbers of leaves, the revolving hand and hour-plate move with the velocities 24 and 22, that is, 60 and 55, as before ſtated. In this mode of indicating time, three pinions without wheels are all that are neceſſary for the motion-work, whereas three wheels and one pinion, or two wheels and two pinions, are uſually wanted to make the velocities of two hands 12 : 1.

But this ſimple mode of indicating time has no connection with the other motions in the upper part of the dial-work, and the indication might be effected in the ordinary way without interfering with what follows, provided the ſtriking work ſhould be introduced and require it. It may be proper to obſerve here, that the long ſide pinion will act better when made not quite conical, but like two pinions, varying a little in diameter, placed cloſe in contact. The ſmall wheel *c* in *fig.* 1, revolves in ſeven days by means of its interior connection with the fuſee-arbor, from which the moving power is taken, and is always detached, by puſhing in the key, during the act of winding, which is performed on the poſterior part; it is not neceſſary to ſtate more particularly how the multiplication from 12 hours to ſeven days ariſes, as the operation is of the ſimpleſt nature; being only as 1 to 14; the arbor of this wheel *c*, which has 32 teeth, carries the ſmall hand that points out the ſeven days of the week in one of the two correſponding ſmall divided circles in *fig.* 2; by this wheel of 32 teeth is a large one of 135 driven, which is concentric with the lunar plate, that is carried round by its arbor in $\frac{135}{32}$ of 7 days, or in $29^d\ 12^h\ 45^m$. The arbor of this large wheel, as well as that of wheel 32, paſſes through both plates of the clock frame, and is therefore ſteady. On the plane of the moon's plate is painted a black ſpiral on a white ground, tapering both ways from the middle in ſuch a way, that the greateſt breadth will juſt cover the round hole made at the top of the dial, through which the moon's preſent aſpect may always be ſeen, as it correſponds to her age. The arbor of the lunar wheel projects and receives three hands; that with a lune on it points out the moon's age in the outermoſt circle of $29\frac{1}{2}$ ſpaces of Arabic characters, and alſo the time of ſouthing in the ſecond circle of Roman numerals; the ſtraight hand indicates the time of high water at each tide in the ſaid ſecond circle, when ſet for any particular place at new moon; and the third hand, that has a croſs near its extremity, ſhews the day of the month in the outermoſt circle, but requires adjuſtment at the end of the month. To the lunar arbor is attached a pinion of 24 leaves, not ſeen, driving a wheel *d*, of 107 teeth round a ſtud in the front plate, and another pinion of 31 leaves, faſt to it, actuates a ſecond wheel of 86 teeth round, in $\frac{107}{24}$ of $\frac{86}{31}$ of $29^d\ 12^h\ 45^m$, which period reduced is $365^d\ 6^h\ 1^m\ 5^s$, and a hand, inſerted on its arbor, points out the month and ſun's place in the ſmall ecliptic, correſponding in ſize to the week circle, in which the days are indicated.

Upon the annual arbor of wheel 86 is alſo put a ſmall circular plate divided into $29\frac{1}{2}$ ſpaces, which fits into a round hole cut in the dial, the arbor being pivoted acroſs the frame, like the lunar and weekly arbors; the uſe of this ſmall plate is to ſhew the moon's place in the contiguous ſmall ecliptic; for whatever be the moon's age indicated in its proper circle, the ſame age looked to, in this little revolving circle of $29\frac{1}{2}$, will be oppoſite the moon's mean place in the ecliptic at that time. Juſt behind the ſmall lunar plate which revolves in a year, and in the ſame plane with the principal dial-plate, are fixed faſt to the annual arbor two other wheels, one of 98 teeth, and the other of 55; the former cloſe behind the dial, and the other contiguous to that; theſe drive each a correſponding wheel round the lunar arbor, conſidered as a common ſtem; the 98 drives a fellow of 93 teeth, and the 55 a fellow of 62; the former pair of wheels regulate the plate of the moon's nodes and latitude, marked on the plane of the wheel itſelf, which is not croſſed, and the other pair carries a double hand, having A at one end, and P at the other, to ſhew when the moon's hand comes in conjunction with the mean apogeal or perigeal point of her variable orbit. At the time the contriver of this clock adopted the numbers for the retrograde motion of the nodes, and progreſſive motion of the apogee and perigee, he was not aware that they had been uſed in orreries, but he has ſince found that the ratios he calculated for theſe purpoſes have been choſen for the like uſes in ſome other inſtruments of illuſtration. According to theſe numbers, the periods produced by the wheel-work are reſpectively $18\frac{3}{5}$, and $8\frac{6}{7}$ civil years: and wherever the lunar hand is ſeen at any time, the latitude is indicated thereby on the innermoſt circle, and the moon's poſition, with reſpect to the apogee or perigee, may be ſeen, and conſequently her apparent diameter and horizontal parallax, depending on her diſtance from the earth, may be judged of at the time of inſpection, and might even be indicated if another ſtill ſmaller plate were marked therewith, and ſubſtituted for the double hand. The poſitions of the reſpective hands, and ſmall plates, are for Monday July 4th, of the year 1808, when the moon's age is 12, her ſituation at perigee, and alſo a little to the north ſide of the aſcending node, the ſun's place, a little ſhort of the middle of Cancer, and the moon's, a few degrees ſhort of the end of Scorpio. In our article CHRONOMETER, we mentioned that the late Margetts contrived the dial-work of his chronometers ſo ingeniouſly, that both ſolar and ſidereal time, in the three different denominations of hours, minutes, and ſeconds, are conſtantly indicated at the ſame time, and conſequently, the ſun's mean right aſcenſion alſo, which is the difference between mean ſolar and ſidereal time, at any given inſtant; and as we promiſed to deſcribe the contrivance under the preſent head, we propoſe to introduce it next.

Fig. 1. of *Plate* XXXIII. is a plan of the wheels and pinions employed in the motion-work, and *fig.* 2. is the repreſentation of the dials, of which there are four, one large and three ſmall, and of the three hands; both figures being of the real ſize. We will explain, *fig.* 1. firſt; after premiſing that we have inſerted the letters of reference *a*, *b*, *c*, *d*, and *e*, on the margin of the face to avoid confuſion, and have referred by dotted ſtraight lines to the centres to which they reſpectively belong, and where the reader is deſired to conceive them placed: at the centre *a*, the hour-wheel or centre-wheel arbor projects, as uſual, from the frame of the chronometer, and takes the minutes-hand round the large circle, beyond the ſmall face to the right in *fig.* 2, in a ſolar hour on a tube of ſteel that fits tight by friction on the ſaid arbor, which tube is ſquared as uſual to receive its hand; to the lower extremity of this tube, or cannon, as the workmen call it, are attached two cannon pinions, the inferior one of 80 leaves,

leaves, and the ſuperior one of 15, both which conſequently revolve together, in the ſame period of one hour; the under pinion of 80, being of ſmall diameter, has its teeth ſo diminutive, that the naked eye can ſcarcely perceive that there are any, and drives the large wheel of 487 teeth round the centre *c*, where a tube ſurrounds the ſolar ſeconds' hand, and forms a ſtud for this wheel, in order that the arbor of the ſeconds' hand, projecting as uſual from the frame, may have no friction from contact, which it would have if the ſaid fixed tube were not interpoſed; the period of this large wheel is $\frac{487}{80}$ of a ſolar hour, or $6^h\ 5^m\ 15^s$, and it carries round with it the loweſt ſmall face in *fig.* 2, in a direction contrary to that of the motion of the ſeconds' hand, which points to its diviſions, and alſo to the fixed diviſions of the circle ſurrounding this ſmall face on the large dial itſelf. Again, the upper cannon pinion, of 15 leaves, actuates one of the two wheels of 75 teeth that revolve on the fuſee's arbor, as on a ſtud, at the point *d*, both of which wheels, being of the ſame diameter and conſtruction, and lying over one another, appear to an eye placed over them in the plan as one wheel; the wheel, however, in queſtion, is the under one, to which a pinion of 15, not ſeen, is attached, that drives the under one of two ſimilar wheels of 72 teeth each, round a ſtud at the point *b*, in the period $\frac{75}{15} \times \frac{72}{15}$ of a ſolar hour, that is, in 24 hours of ſolar time; and upon a tube on this under wheel of 72 is the ſolar hour hand placed, that revolves in an exact ſolar day, and indicates the 24 hours of mean ſolar time on the large circle of Roman characters, that ſurrounds the left-hand ſmall face. Thus, the three hands indicate the ſolar hours, minutes, and ſeconds on the three fixed circles of the large plate or dial. We have already ſeen, that the great wheel of 487 teeth revolves, by its connection with the cannon pinion, of 80, in $\frac{487}{80}$ of an hour, or in $6^h\ 5^m\ 15^s$, which period is exactly $365\frac{1}{4}$ minutes of ſolar time; to this wheel a pinion of 12 leaves is faſt, that impels a wheel of 72 teeth round a ſtud, or pin, on the cock *f*, that lies over a part of wheel 487, at the point *e*; this wheel has again a pinion faſt to it of 8 leaves, that impels the wheel of 80 teeth round the cannon at *a*, in $\frac{72}{12} \times \frac{80}{8} = \frac{60}{1}$ of $365\frac{1}{4}$ minutes, which period is $15^d\ 5^h\ 15^m$, or $365\frac{1}{4}$ hours; and to the tube of this wheel of 80 the retrograde right-hand ſmall plate, or dial, is attached by friction, and, conſequently, revolves with it, as the ſmall dial on the inferior part of the face does with the large wheel of 487, to which it is alſo attached by the friction of their tubes; and, laſtly, a train of $\frac{75}{15} \times \frac{72}{15}$, in every reſpect ſimilar to the one of this denomination, already deſcribed, converts the $365\frac{1}{4}$ hours into $365\frac{1}{4}$ days, for the period of the third, or left-hand ſmall dial's retrograde revolution; that is, the pinion of 15, faſt to the wheel of 80 teeth, drives the upper 75 round the point *d*, and its pinion of 15 again drives the upper 72 in the manner before deſcribed, the train being, in both caſes, equal to $\frac{24}{1}$. Now, the manner in which ſidereal time is indicated is, by means of the ſolar hands pointing to the three ſmall dials that revolve in a retrograde direction, as they regard theſe hands, in $365\frac{1}{4}$ days, $365\frac{1}{4}$ hours, and $365\frac{1}{4}$ minutes reſpectively; the ſidereal hours, minutes, and ſeconds being ſhorter in duration than ſolar ones, by ſuch a minute quantity, as amounts, in the aggregate, to an entire ſidereal day in a year, conſtitute that ſpecies of time which is uſed as the meaſure of the right aſcenſion of any of the heavenly bodies, and which is itſelf meaſured by the earth's abſolute rotations on its axis, as they have a reference to a ſtar, or any fixed point in the heavens; whereas, ſolar, or common time, is meaſured by the ſaid rotations, as they reſpect the ſun, in apparent motion; which apparent motion is the conſequence of the earth's annual progreſs in the ecliptic. The difference between a ſolar and ſidereal day, in ſolar time, is ſomewhat leſs than four minutes, or $3^m\ 56^s.55$, ſo that a difference, or acceleration of ſidereal, on ſolar time of one ſecond, takes place in about ſix minutes of ſolar time, namely, in $\frac{365^m.25638}{60} = 6^m.0876$; hence, ſuppoſing the figures of the ſmall dials to be put, at any time, to coincide with the ſame figures on the circles ſurrounding them on the fixed face, after about ſix minutes, or entire revolutions of the ſolar ſeconds'-hand, the revolving ſeconds'-face or ſmall dial, ought to fall back *one ſecond ſpace*, but the other two ſmall dials will appear unaltered, by reaſon of the ſlowneſs of their motion; in the next ſix minutes *two ſeconds* of difference will be indicated by the ſeconds'-hand, *i. e.* the ſolar ſeconds will be pointed to on the fixed face, and ſidereal ſeconds on the moveable dial, which, therefore, we call the ſidereal ſeconds'-dial, and the difference of the two indications will be two ſeconds; in like manner, after ſixty ſuch periods of ſix minutes nearly, that is, after upwards of ſix hours, one minute-ſpace of difference will be indicated by the minutes'-hand, when the time, ſhewn on the moveable dial, is compared with the time on the fixed circle of minutes, and the ſeconds'-hand will now, as at firſt, indicate both ſolar and ſidereal ſeconds alike, by reaſon of the firſt minute of difference being completed; and thus, in the courſe of the whole 24 ſolar hours, there will be a difference of nearly four minute ſpaces ſhewn by the minute hand; but as yet there is ſcarcely any alteration perceptible in the hour-circles, nor will there be a difference of one hour's ſpace till upwards of 15 days have tranſpired. Strictly ſpeaking, the period in which the acceleration will amount to a ſecond, by the wheel-work, will be $\frac{487}{80}$ of a minute, or 6.0875 minutes, and as the annual period of the retrograde motion of the ſidereal hour-dial is $365^d\ 6^h\ 0^m$, inſtead of $365^d\ 6^h\ 9^m\ 11^s.5$, the whole error in the indication of ſidereal time, by the ſolar hands pointing to the ſidereal, or moveable dials, will be little more than one ſecond and a half in a ſidereal year, which, it will be allowed, is hardly worth naming. The adjuſtment of the dials is performed by the ſun's mean right aſcenſion, which is determined from the apparent right aſcenſion, given for noon of each day, in the Nautical Almanac, and in White's Ephemeris, by applying the equation of time, together with the acceleration added thereto, at the rate of one ſecond in each ſix minutes of equation, to convert it into ſidereal time; but care muſt be taken to apply the equation with a contrary ſign, to what is applied when apparent ſolar time is converted into mean. When the ſun's mean right aſcenſion is thus obtained in hours, minutes, and ſeconds, at the noon of any day, the hour on the ſidereal hour-dial muſt be put to coincide with XII on the ſolar dial, the minutes on the ſidereal minute-dial muſt be put to coincide with 60 on the ſolar minute-dial, and the ſeconds ſo determined muſt be put as counted on the ſidereal ſeconds'-dial to 60 on the ſolar ſeconds'-plate, in which ſituation of things, the chronometer will indicate not only ſolar and ſidereal time, but alſo the ſun's mean right aſcenſion at mean noon, from which the ap-

parent right aſcenſion may be obtained, by the application of the equation of time, increaſed by the acceleration, with the ſign ſet down in the almanac. In *fig.* 2, the rectification of the dials and hands is for the 3d of Sept. 1808, when the ſolar time is noon or 24^h, the ſidereal is $10^h\ 49^m\ 46^s$, the ſun's mean right aſcenſion alſo $10^h\ 49^m\ 46^s$, and the equation — 50″, which makes the apparent right aſcenſion $10^h\ 48^m\ 56^s$, agreeably to the almanac.

From this view of the dial-work of Margett's chronometers, it is eaſy to ſee, that when the ſolar time is accurately indicated, the ſidereal time correſponding muſt neceſſarily be indicated, accurately too, within a ſecond in the firſt eight months after rectification, and within two ſeconds for the next eight months, and ſo on for any length of time; and when the time of rectification has been noted, the error may be applied, as a rate, if neceſſary, at any ſubſequent period, which conſideration annihilates the objection to a want of complete accuracy. The motions produced by the wheels and pinions in this complex motion-work, being all very ſlow, deduct very little from the maintaining power, ſo little, indeed, as to be abſolutely imperceptible in practice, particularly when a good detached eſcapement is uſed. The uſe of ſuch dial-work in a chronometer, that is regulated by a tranſit inſtrument, muſt be evident to every perſon ſkilled in aſtronomy, navigation, or that branch of ſurveying which has to do with long lines, the bearings of which are aſcertained by the greateſt elongations of the pole ſtar. The ſmall dials will tell, at all periods of day or night, throughout the year, what heavenly bodies, the right aſcenſions of which are previouſly known, are on or near the meridian of the place for which the chronometer has its time adjuſted.

We might enlarge this article by the addition of various other contrivances, introduced by ingenious workmen into the dial-work of clocks and watches, but we will ſatisfy ourſelves with a deſcription of a curious method of indicating time that has hardly yet gained a name, but which ranks among the other modes of pointing out time, though it has not yet been made public. A German mechaniſt happened to be at Copenhagen, ſelling a valuable clock which he had contrived and made, when the Engliſh cauſed that city to capitulate, and the artizan was brought over to England, where he remains in effect a priſoner; being thus ſeparated from his family, and having no means of ſubſiſtence but his ſkill in mechanics, he invented the contrivance we are going to give a brief ſketch of, and the plan of which is given in *fig.* 3, of *Plate* XXXIII. A B is a circle of braſs divided into twelve hours, and ſub-divided into five minute ſpaces, which circle is ſupported, as ſeen in the figure, in a vertical poſition on a wooden baſe; C and D are two weights, apparently balanced on the oppoſite ends of a bar, that turns on an axis, placed horizontally at right-angles, and ſupported by a bearer in the ſhape of a fiſh reſting on its head, the counterpoiſe C is ornamented with a ſtar for the ſake of a deception, that the mind may not be induced to ſuppoſe that any mechaniſm is included. The curioſity, as well as utility of the contrivance, conſiſt in this apparently ſelf-acting principle; move the bar, that now reſts at $7^h\ 55^m$, forcibly round, ſo as to give it conſiderable velocity, and it will continue to ſpin round for ſome time, but whenever it comes to reſt, it will come to a ſtate of quieſcence, at any hour and minute of the day or night, with its index at the very point of the large divided circle that the preſent hour and minute require, though a ſuperficial view of the thing will not diſcover any cauſe for ſuch tendency to reſt always at the preſent hour and minute, any more than the polarity of a magnetic needle can be diſcovered by ocular examination. The fact, however, is, that a watch is contained in the box C, which makes a wheel revolve in twelve hours, that is loaded with a weight heavy enough to alter the common centre of gravity of the loads C and D, as the ſaid wheel revolves, thereby throwing the centre of gravity to the right and left of the axis of motion alternately, and cauſing the ends of the bar, with its loads, to preponderate alternately, and, conſequently, to revolve gradually from XII round to XII again, as the watch governs the rate. It will be ſeen, however, that the velocity of the bar will not be uniform in every part of its revolution, becauſe the coſines of the angles, denoted by equal times, do not vary by equal quantities, and the ingenious remedy for the natural inequalities of motion among the equally divided ſpaces of the circle, conſtitutes the ſecret on which the accuracy of the thing, as a meaſure of time, depends, when the watch is good, and which, therefore, we feel not at liberty to diſcloſe under the preſent circumſtances of the manufacturer. We underſtand, that their royal highneſſes the dukes of York and Kent have purchaſed each one of theſe horoſcopes, as they may be not improperly called, as has alſo general Campbell; and Meſſrs. Rundell and Co. of Ludgate-hill, have kindly undertaken to vend this ingenious article for the benefit of the inventor, who puts no higher price on it than about ſeven guineas.

DIALECT, Διαλεκτος, from Διαλεγεσθαι, *to diſcourſe*, the peculiar language of ſome province, or part, of a nation, formed by corruption of the general, or national language.

Homer could ſpeak five different languages in one verſe, *i. e.* five dialects; *viz.* the Attic, Ionic, Æolic, the Doric, and the common dialect of the Greeks.

The Attic dialect is that which was uſed in Athens and the adjacent country; and it was more particularly uſed by Xenophon, Thucydides, Ariſtophanes, Plato, Iſocrates, and Demoſthenes. The Ionic was almoſt the ſame with the ancient Attic; but after it had paſſed into ſeveral towns of Aſia Minor, and into the adjacent iſlands, which were colonies of the Athenians, and of the people of Achaia, it received a ſort of new tincture, and did not attain to that perfect delicacy which the Athenians afterwards acquired. It was uſed by Herodotus and Hippocrates. The Doric was firſt in uſe among the Spartans, and the people of Argos; it paſſed afterwards into Epirus, Libya, Sicily, Rhodes, and Crete. Archimedes and Theocritus, both of them Syracuſans, and Pindar, adopted this dialect. The Æolic dialect was at firſt uſed by the Bœotians and their neighbours, and then in Æolis, a country of Aſia Minor, between Ionia and Myſia, which contained 10 or 12 cities that were Grecian colonies. Sappho and Alcæus wrote in this dialect. We find alſo a mixture of it in the writings of Theocritus, Pindar, Homer, and many others.

The Bologneſe, Bergamaſque, Tuſcan, &c. are the dialects of the Italian; the Gaſcon, and Picard, are dialects of the French.

In Great Britain, almoſt every county has a dialect of its own, all differing conſiderably in pronunciation, accent, and tone, though the language be the ſame.

The method which the Gileadites took to prove the Ephraimites, by the pronunciation of *ſhibboleth*, with *ſchin*, or *ſamech*, is well known. Judges, xii. 6.

DIALECTICA, Dialectics, Διαλεκτικη, the art of reaſoning and diſputing juſtly.

The word comes from the Greek διαλεγομαι, *I diſcourſe*, formed of δια, and λεγω, *dico*, *I ſay*.

Zeno Eleates is ſaid to have been the firſt who diſcovered the natural ſeries of principles and concluſions obſerved in reaſoning, and formed an art thereof, in form of a dialogue;

which, for this reaſon, was called dialectica. Brucker (Hiſt. Philoſ. by Enfield, vol. i. p. 421.) ſays, that the invention of the dialectic art has been improperly aſcribed to Zeno; though there can be no doubt that this philoſopher, and other metaphyſical diſputants of the Eleatic ſect, employed much ingenuity and ſubtlety in exhibiting examples of moſt of the logical arts, which were afterwards reduced to rule by Ariſtotle and others.

The dialectica of the ancients is uſually divided into ſeveral kinds: the firſt was the Eleatica, that of Zeno Eleates, which was threefold: *viz.* conſecutionum, colloquationum, and contentionum. The firſt conſiſting of rules for deducing, or drawing concluſions; the ſecond, the art of dialogue; which became of ſuch univerſal uſe in philoſophy, that all reaſoning was called interrogation; then ſyllogiſm being laid aſide, the philoſophers did all by a dialogue; it lying on the reſpondent to conclude and argue from the ſeveral conceſſions made. The laſt part of Zeno's dialectics, ερισικη, was contentious; or the art of diſputing, and contradicting: though ſome, particularly Laertius, aſcribe this part to Protagoras, a diſciple of Zeno.

The ſecond is the Dialectica Megarica, whoſe author is Euclid, not the mathematician, but another, of Megara. He gave much into the method of Zeno, and Protagoras; though there are two things appropriated to him: the firſt, that he impugned the demonſtrations of others, not by aſſumptions, but concluſions; continually making illations, and proceeding from conſequence to conſequence; the ſecond, that he ſet aſide all arguments drawn from compariſons, of ſimilitude, as invalid.

He was ſucceeded by Eubulides, from whom the ſophiſtic way of reaſoning is ſaid to be derived. In his time the art is deſcribed as manifold: mentiens, fallens, electra, obvelata, arcevalis, cornuta, and calva. See SOPHISM.

The third is the dialectics of Plato, which he propoſes as a kind of analyſis, to direct the human mind by dividing, defining, and bringing things to the firſt truth; where being arrived, and ſtopping there a little, it applies itſelf to explain ſenſible things; but with a view to return to the firſt truth, where alone it can reſt.

The ſum of his doctrine on dialectics, as collected from his dialogues, is this: Truth is diſcerned, not by the ſenſes, but by the underſtanding; the human intellect is employed, either upon things which it comprehends by itſelf, and which are in their nature ſimple and invariable, or upon things which are ſubject to the ſenſes, and which are perpetually liable to fluctuation and change. The contemplation of the former creates ſcience; attention to the latter produces opinion. Senſe is the paſſive perception of the ſoul through the medium of the body. When the forms of things are, by means of the corporeal organs, ſo deeply impreſſed upon the mind, as not to be eaſily effaced by time, this permanent impreſſion is called Memory. From the union of ſenſe and memory, or from the compariſon of a preſent with a recollected perception, ariſes Opinion: when theſe agree, the opinion is true; when they differ, it is falſe. The ſeat of perception and memory is like a waxen tablet, or picture, which the mind contemplates, and thence frames opinions. In meditation, the ſoul converſes with itſelf: thought flows through the lips by means of the vocal organs. Intellection is the operation of the underſtanding, contemplating intelligible forms, or ideas. It is twofold; the firſt, that of the ſoul contemplating ideas before it deſcends into the body: the other, that which it exerciſes after it is immerſed in the body, which may be alſo termed natural knowledge. This kind of knowledge conſiſts in the recollection of thoſe things which the mind had known in its pre-exiſtent ſtate, and differs from memory in the object; memory being employed upon ſenſible things, reminiſcence upon things purely intelligible. The intelligible objects of contemplation are either primary or ſecondary: the primary are ideas; the ſecondary are the forms inſeparable from material objects. The mind, in exerciſing its judgment, conſiders theoretically what is true or falſe, and practically what may, or may not be done. Dialectics conſider the eſſence and the accidents of things; concerning the former, as we have already obſerved, it makes uſe of diviſion, definition, and analyſis. Diviſion ſeparates the genus into its ſpecies, the whole into its parts, and the like. Definition expreſſes the genus, or the thing to be defined, and diſtinguiſhes it from all others by adding its ſpecific difference. Analyſis riſes from objects of ſenſe to intelligibles; from demonſtrable propoſitions to axioms, or from hypotheſis to experience. Induction riſes from individuals to univerſals. Syllogiſm produces a concluſion by means of ſome intermediate propoſition. Theſe topics are curſorily touched upon by Plato; and it is rather by examples, than by precepts, that he teaches the true art of reaſoning, or expoſes the fallacies of ſophiſtry.

The fourth is Ariſtotle's dialectics, containing the doctrine of ſimple words, delivered in his book of "Predicaments:" the doctrine of propoſitions, in his book "De Interpretatione;" and that of the ſeveral kinds of ſyllogiſm, in his books of "Analytics," "Topics," and "Elenchuſes." See ARISTOTLE and LOGIC.

The fifth is the dialectics of the Stoics, which they call a part of philoſophy, and divide into rhetoric, and dialectic; to which ſome add the definitive, whereby things are juſtly defined, comprehending, likewiſe, the canons, or criterions, of truth. See LOGIC.

The Stoics, before they come to treat of ſyllogiſms, have two principal places; the one about the ſignification of words; the other, about the thing ſignified. On occaſion of the firſt, they conſider abundance of things belonging to the grammarian's province: what, and how many letters; what is a word, diction, ſpeech, &c. On occaſion of the latter, they conſider things themſelves, not as without the mind, but as in it, received in it by means of the ſenſes. Accordingly, they firſt teach, that "nil ſit intellectu, quod non prius fuerit in ſenſu;" whatever is in the mind, came thither by the ſenſes; and that, "aut incurſione ſui," as Plato, who meets the ſight; "aut ſimilitudine," as Cæſar by his effigy; "aut proportione," either by enlarging, as a giant, or by diminiſhing, as a pigmy; "aut tranſlatione," as a Cyclops; "aut compoſitione," as a Centaur; "aut contrario," as death; "aut privatione," as a blind man.

Concerning the whole buſineſs of dialectics, as it appears to have been conducted by the Stoics, we may exclaim with Seneca: "O pueriles ineptias! in hoc, ſupercilia ſubduximus? in hoc, barbara demiſſimus? hoc eſt, quod triſtes docemus, et pallidi?"

The ſixth is Epicurus's dialectics. For though he ſeems to have deſpiſed dialectic, he cultivated it with vigour: he was only averſe to that of the Stoics, who he thought attributed too much to it; as pronouncing him alone wiſe, who was well verſed in dialectics. For this reaſon, Epicurus ſeeming to ſet aſide the common dialectics, as only productive of thorny diſputes, idle quibbles, and fruitleſs cavilling, had recourſe to another way; *viz.* to certain canons, which he ſubſtituted in their ſtead, the collection whereof he called canonica; and as all queſtions in philoſophy are either *de re*, or *de voce*, he gave ſeparate rules for each. See EPICUREANS.

The dialectic philoſophy, loaded with metaphyſical ſubtleties, which had been ſtudied and profeſſed by ſeveral of the clergy towards the cloſe of the 11th century, began, at the opening

opening of the 12th, to be publicly taught in the ſchools, and to take the lead of every other kind of learning.

Abelard devoted himſelf to this kind of ſtudy at the commencement of his literary career, and in the review of this part of his courſe, he obſerves, that philoſophy was thus waſting its ſtrength upon trifles, and that, at this time, it was, perhaps, more than ever, the employment of the philoſophical world to diſpute *de lana caprina*. Dialectic philoſophy was now in high eſteem, from a notion, that it was the key of theology, without which it would be impoſſible to unlock the myſteries of ſacred wiſdom. It was on account of this ſuppoſed alliance between logic and theology, that the former was made the principal object of ſtudy in all the ſchools, and that thoſe who excelled in the dialectic art were regarded with the higheſt admiration, and attended by crowds of pupils. Beſides, the logical and metaphyſical writings of Ariſtotle were ſtudied in the Saracen ſchools in Spain, and induſtriouſly diſperſed through France, Germany, and Italy. It was alſo about this time that many Greek copies of the works of Ariſtotle were brought from Conſtantinople into the weſt. By degrees the fondneſs for the ſubtleties of Ariſtotelian logic and metaphyſics became ſo general, that the orthodox clergy complained, that ſcholars ſpent their whole time in diſputation. Their complaints and their prohibitions were, however, ineffectual; and at length it was found neceſſary, under certain reſtrictions, to favour the ſtudy of Ariſtotle. In proceſs of time, and by no very ſlow gradation, the Ariſtotelian dialectics became intimately connected with theology, and on this account obtained the zealous patronage of thoſe who preſided in the church; ſo that almoſt the whole Chriſtian church became ſcholaſtics. (See SCHOLASTICS.)

At length, about the time of the reformation, many learned men, particularly Valla, Agricola, and Vives, ſpoke with great freedom of the defects of the Ariſtotelian logic; but no one attempted to introduce a better in the room of it, till Peter Ramus undertook the taſk, and executed it with a degree of courage and ſucceſs, which has juſtly given his name conſiderable celebrity. (See RAMUS.) The fame of Ramus, however, vaniſhed before that of Des Cartes; and the ultimate demolition of the Ariſtotelian philoſophy, as it reſpects the ſubject of this article, was principally owing to the labours of the celebrated Mr. Locke, and to the eſſay on the Human Underſtanding. See LOGIC.

DIALECTICAL ARGUMENTS, in *Logic*, are ſuch as are only probable, and do not convince, or determine, the mind abſolutely to either ſide of the queſtion.

DIALIA, in *Antiquity*, ſacrifices performed by the flamen dialis, or prieſt of Jupiter.

It was not, however, of ſuch abſolute neceſſity, that the Dialia ſhould be performed by the flamen dialis; but that others might officiate. We find in Tacitus, Annal. lib. ii. cap. 58. that if he were ſick, or detained by any other public employ, the pontifices took his place.

DIALIS, a Latin term, ſignifying ſomewhat that belongs to Jupiter.

The word is formed from Διος, the genitive of Ζευς, *Jupiter*.

DIALIS, *Flamen*. See FLAMEN.

DIALISIS. See DIALYSIS.

DIALITHA, from δια, and λιθος, *gem*, in the *Writings of the Ancients*, a word uſed to expreſs the elegant ornaments of the Greeks and Romans, compoſed of gold and gems. They alſo called theſe lithocolla, cemented ſtones or gems, the gold being in this caſe, as a cement, to hold the ſtones together. They wore bracelets, and other ornamental things about their habits, thus made; and their cups and table-furniture for magnificent treats were of this kind. The green ſtones were found to ſucceed beſt of all in theſe things; and the emerald and greeniſh topaz, or, as we call it, chryſolite, are moſt in eſteem for this purpoſe. This uſe of the ſtone explains what Pliny very often ſays of them in his deſcription: "Nihil jucundius aurum decet: nothing becomes gold better." This he ſays of the green topaz or chryſolite; and this, and many other like paſſages, have greatly perplexed the critics who did not hit upon this explication. The Latins called theſe dialitha, lithocolla, and aurum gemmatum; and thus Martial, where he ſays "miratur Scythicas virentis auri flammas Jupiter," alludes to cups of gold, ornamented with Scythian gems, that is, emeralds.

DIALIUM, in *Botany*, Linn. Mant. 3. Schreb. 14. Willd. Sp. Pl. v. 1. 49. Vahl. Enum. v. 1. 303. Juſſ. 424. Afzel. Gen. Pl. Guin. p. 1. 13. (Aruna; Schreb. 26. Willd. Sp. Pl. v. 1. 156. Arouna; Aubl. Guian. v. 1. 16. Juſſ. 366.) Claſs and order, *Diandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminoſæ*, Juſſ. The origin of the name we have not been able to diſcover.

Gen. Ch. reformed. *Cal.* Perianth irregular; in five deep ſegments, equal in length, ovate, obtuſe, concave. *Cor.* none. *Stam.* Filaments two, awl-ſhaped, ſituated at the upper ſide of the receptacle; anthers not extending beyond the calyx-leaves, oblong, obtuſe, heart-ſhaped at the baſe, of two lobes and two cells. *Piſt.* Germen ſuperior, nearly ſeſſile, ovate, oblique, downy; ſtyle awl-ſhaped, the length of the ſtamens, ſmooth at the ſummit, and ſomewhat recurved; ſtigma ſimple, obtuſe. *Peric.* Legume, internally pulpy, with one or two compreſſed ſeeds.

Eſſ. Ch. Calyx in five deep ſegments. Corolla none. Stamens at the upper ſide of the flower. Legume nearly ſeſſile, pulpy within.

1. D. *indum*. Linn. Mant. 24. Willd. Sp. Pl. v. 1. 49. Vahl. Enum. v. 1. 303. (D. javanicum; Burm. Ind. 12.) Leaflets ſmooth on both ſides, elliptic-oblong. Anthers thrice as long as the filaments.——A native of Java, where it is called, in the Malay language, *Coerandie*. It is a tree, with alternate pinnated leaves; leaflets ſeven, alternate, on ſhort thick round ſmooth partial ſtalks, elliptic-oblong, inclining to ovate, pointed, entire, veiny, ſmooth on both ſides, except a bliſtery appearance underneath. Panicles cluſtered, axillary and terminal; their branches downy, alternate, compound and racemoſe, ſome of the lower ones rather corymboſe. Flowers drooping, reddiſh, the ſize of *Clethra alnifolia*, externally downy. Segments of the calyx elliptical, obtuſe, concave, three of them external. Filaments very ſhort and thick. Anthers large, full thrice as long, with a deep furrow on each ſide between their lobes, and a ſlighter one along their edges. Germen ſeſſile, ovate, pointed, oblique, ſilky, with a gland at its baſe. Style awl-ſhaped, recurved and ſmooth at the ſummit. Ripe fruit unknown.

Concerning this plant there has been much uncertainty. Our deſcription is taken from the original ſpecimen in the Linnæan Herbarium, which Dr. Afzelius alſo inveſtigated. See his Diſſertation above quoted. His object was to diſtinguiſh it generically from his *Codarium*, preſumed to be the *Dialium guineenſe* of Willdenow. (See CODARIUM.) In doing this, Dr. Afzelius juſtly terms calyx what Linnæus calls corolla. It is ſingular that Vahl ſhould not have made his own elaborate deſcriptions of theſe two genera accord in this particular. The fruit of the *Codarium acutifolium* of Afzelius, (*C. nitidum* of Vahl.) is called at Sierra Leone the Velvet Tamarind, its pulp being agreeably acid and nutritious. Another ſpecies, found in the country vulgarly called Cape Coaſt, is termed by Afzelius *C. obtuſifolium*; "Leaflets equal in ſize, rounded at their points."

2. D. *divaricatum*. Vahl. Enum. v. 1. 303. (Arouna guianenſis; Aubl. Guian. v. 1. 16. t. 5. Aruna divaricata; Willd. Sp. Pl. v. 1. 156.) Leaflets downy beneath, ovate,

oblique at the baſe. Anthers roundiſh, ſcarcely ſo long as the filaments.—Gathered by Aublet, (one of whoſe own ſpecimens is now before us) in the great foreſts of Guiana, towards the river Sinemari. This is a tree 30 or 40 feet high, flowering in November, and bearing fruit in March. Branches round, tuberculated, leafy. Leaves alternate, three or four inches long, pinnate; leaflets uſually five or ſeven, alternate, on ſhort thick round downy partial ſtalks, ovate, pointed, entire, veiny, oblique or ſloped off at their baſe; ſmooth or nearly ſo above, finely downy and ferruginous beneath, eſpecially their ribs and veins. The partial ſtipulas, deſcribed and figured by Aublet, are declared by Vahl not to exiſt, nor do we find them in our ſpecimen. Panicles much ſmaller than in the firſt ſpecies, and rather more divaricated, clothed with ruſty down, their branches corymboſe. Unexpanded flowers the ſize of muſtard ſeed, ovate, ſhort and thick, ruſty. Calyx at length reflexed, apparently permanent. Stamens ſomewhat diſtant. Anthers ſhort, heart-ſhaped. Germen ſilky, nearly ſeſſile in the diſk of an annular receptacle, without any peculiar gland. Style twiſted. Fruit, according to Aublet, an oval, ſlightly compreſſed, capſule, or rather pod, containing one or two ſeeds lodged in reddiſh acid pulp. One of the ſeeds is often abortive.

We venture to follow Vahl in uniting theſe two plants under one genus, notwithſtanding the fruit of the former being unknown, and ſome ſlight diſcrepancy in the poſition or ſituation of their ſtamens. In habit they are ſufficiently akin. Can the apparent gland, hitherto unnoticed, which we have found in *D. indum* be the rudiment of a petal? If ſo, it brings this ſpecies very near to *Codarium*. S.

DIALLACTERII, among the Athenians. See DIÆTETÆ.

DIALLELOS, Διαλληλος, in *Rhetoric*, a figure, wherein the words and meaning of a ſentence are inverted, as doctis diſertior, diſertis doctior. Voſſ. Rhet. lib. v. p. 405.

DIALLING, the art of drawing ſun, moon, and ſtar-dials, on any given plane, or on the ſurface of any given body. See DIAL.

The Greeks and Latins call this art gnomonica, and ſciatherica, becauſe it diſtinguiſhes the hours by the ſhadow of a gnomon. Some call it photo-ſciatherica, becauſe the hours are ſometimes ſhewn by the light of the ſun. Laſtly, others call it horologiography.

Dialling is wholly founded on the firſt motion of the heavenly bodies, and chiefly the ſun; or rather on the diurnal rotation of the earth; ſo that the elements of ſpherics, and the ſpherical aſtronomy, ſhould be maſtered, before a perſon advances to the doctrine of dialling: the doctrine, or theory, we ſay, for as to the practice, or the operations themſelves diſtinct from the demonſtrations, nothing is more eaſy and obvious.

The principles of dialling may be eaſily deduced from the method, already illuſtrated, of conſtructing dials by the globe. Or, they may be farther explained, by ſuppoſing the whole earth P *c p* (*Plate* IV. *fig.* 36.) to be tranſparent and hollow, like a ſphere of glaſs, and its equator to be divided into twenty-four equal parts by ſo many meridian ſemicircles *a*, *b*, *c*, *d*, *e*, *f*, *g*, &c. one of which is the geographical meridian of any given place, as London, which is ſuppoſed to be at the point *a*; and if the hour of XII were marked at the equator, both upon that meridian and the oppoſite one, and all the reſt of the hours in order on the other meridians, thoſe meridians would be the hour-circles of London: becauſe, as the ſun appears to move round the earth, which is in the centre of the viſible heavens, in twenty-four hours, he will paſs from one meridian to another in an hour. Then, if the ſphere had an opake axis, as P E *p*, terminating in the poles P and *p*, the ſhadow of the axis, which is in the ſame plane with the ſun, and with each meridian, would fall upon every particular meridian and hour, when the ſun came to the plane of the oppoſite meridian, and would conſequently ſhew the time at London, and at all other places on the ſame meridian. If this ſphere was cut through the middle by a ſolid plane A B C D in the rational horizon of London, one half of the axis E P would be above the plane, and the other half below it; and if ſtraight lines were drawn from the centre of the plane to thoſe points where its circumference is cut by the hour-circles of the ſphere, theſe lines would be the hour-lines of the horizontal dial for London; for the ſhadow of the axis would fall on each particular hour-line of the dial, when it fell upon the like hour-circle of the ſphere. If the plane which cuts the ſphere be upright as A F C G (*fig.* 37.) touching the given place, *e. g.* London, at F, and directly facing the meridian of London, it will then become the plane of an erect direct ſouth dial; and if right lines be drawn from its centre E, to thoſe points of its circumference where the hour-circles of the ſphere cut it, theſe will be the hour-lines of a vertical or direct ſouth dial for London, to which the hours are to be ſet in the figure, contrary to thoſe on a horizontal dial; and the lower half E *p* of the axis will caſt a ſhadow on the hour of the day in this dial, at the ſame time that it would fall upon the like hour-circle of the ſphere, if the dial plane was not in the way. If the plane, ſtill facing the meridian, be made to incline, or recline, any given number of degrees, the hour-circles of the ſphere will ſtill cut the edges of the plane in thoſe points to which the hour-lines muſt be drawn ſtraight from the centre; and the axis of the ſphere will caſt a ſhadow on theſe lines at the reſpective hours. The like will ſtill hold, if the plane be made to decline by any given number of degrees from the meridian towards the eaſt or weſt; provided the declination be leſs than 90 degrees, or the reclination be leſs than the co-latitude of the place; and the axis of the ſphere will be the gnomon; otherwiſe, the axis will have no elevation above the plane or the dial, and cannot be a gnomon.

Thus it appears, that the plane of every dial repreſents the plane of ſome great circle on the earth, and the gnomon the earth's axis; the vertex of a right gnomon the centre of the earth or viſible heavens; and the plane of the dial is juſt as far from this centre as from the vertex of this ſtyle. The earth itſelf, compared with its diſtance from the ſun, is conſidered as a point; and therefore, if a ſmall ſphere of glaſs be placed upon any part of the earth's ſurface, ſo that its axis be parallel to the axis of the earth, and the ſphere hath ſuch lines upon it, and ſuch planes within it, as above deſcribed, it will ſhew the hours of the day as truly as if it were placed at the earth's centre, and the ſhell of the earth were as tranſparent as glaſs. Ferguſon, ubi ſupra. See GNOMONIC *Projection*.

The principal writers on dialling are, Vitruvius, Sebaſtian Munſter, John Dryander, Conrade Geſner, Andrew Schoner, Fred. Commandine, Joan. Bapt. Benedictus, J. G. Schomberg, Solomon de Caus, J. B. Trolta, Deſargues, Kircher, Hallum, J. Mark, and Clavius, who demonſtrates all, both the theory and the operations, after the rigid manner of the ancient mathematicians; but ſo intricately, that probably few ever read them: Dechales, Ozanam, and Schottus, give much eaſier in their Courſes, and Wolfius in his Elements.

M. Picard has given a new method of making large dials by calculating the hour-lines; and M. de la Hire, in his Dialling, printed in 1683, a geometrical method of drawing hour-lines from certain points, determined by obſervation. Eberhardus Walperus, in 1625, publiſhed his Dialling, wherein

wherein he lays down a method of drawing the primary dials on a very eaſy foundation. The ſame foundation is deſcribed at length by Sebaſtian Munſter, in his Rudimenta Mathematica, publiſhed in 1651. Sturmius, in 1672, publiſhed a new edition of Walperus's Dialling, with the addition of a whole ſecond part, about inclining and declining dials, &c. In 1708, the ſame work, with Sturmius's additions, was republiſhed with the addition of a fourth part, containing Picard's and De la Hire's methods of drawing large dials, which makes much the beſt, and fulleſt book on the ſubject. Peterſon, Michael, and Muller, have each written on dialling, in the German tongue; Coetſius, in his Horologiographia Plana, printed in 1689; Gauppenius, in his Gnomonica Mechanica; Leybourn, in his Dialling, fol.; Bion, in his Uſe of Mathematical Inſtruments; and Wells, in his Art of Shadows. We have a treatiſe by M. Deparcieux, in 1740. Mr. Ferguſon has alſo written on this ſubject in his Lectures on Mechanics: Mr. Emerſon, in the 9th volume of his works; and Mr. W. Jones, in his Inſtrumental Dialling.

Dialling *Cylinder, Univerſal*, is repreſented by *fig.* 38. A B C D is a glaſs cylindrical tube, cloſed at both ends with braſs plates, in the centres of which a wire or axis E F G is fixed. The tube is either fixed to an horizontal board H, ſo that its axis may make an angle with the board equal to that which the earth's axis makes with the horizon of any given place, and be parallel to the axis of the world; or it may be made to move on a joint, and elevated for any particular latitude. The twenty-four hour-lines are drawn with a diamond on the outſide of the glaſs, equidiſtant from each other, and parallel to the axis. The XII next B ſtands for midnight, and the XII next the board H for noon. When the axis of this inſtrument is elevated according to the latitude, and the board ſet level with the line H N in the plane of the meridian, and the end N towards the north, the axis E F G will ſerve as a gnomon or ſtyle, and caſt a ſhadow on the hour of the day among the parallel hour-lines, when the ſun ſhines on the inſtrument. As the plate A D at the top is parallel to the equator, and the axis E F G perpendicular to it, right lines drawn from the centre to the extremes of the parallels will be the hour-lines of an equinoctial dial, and the axis will be the ſtyle. An horizontal plate *e f* put down into the tube, with lines drawn from the centre to the ſeveral parallels cutting its edge, will be an horizontal dial for the given latitude; and a vertical plate *g c*, fronting the meridian and touching the tube with its edge, with lines drawn from its centre to the parallels, will be a vertical ſouth dial: the axis of the inſtrument ſerving in both caſes for the ſtyle of the dial; and if a plate be placed within the tube, ſo as to decline, incline, or recline, by any given number of degrees, and lines being drawn, as above, a declining, inclining, or reclining dial will be formed for the given latitude. If the axis with the ſeveral plates fixed to it be drawn out of the tube, and ſet up in ſunſhine in the ſame poſition they were in the tube, A D will be an equinoctial dial, *e f* an horizontal dial, and *g c* a vertical ſouth dial, and the time of the day will be ſhewn by the axis E F G. If the cylinder were wood, inſtead of glaſs, and the parallel lines drawn upon it in the ſame manner, it would ſerve to facilitate the operation of making theſe ſeveral dials. The upper plate with lines drawn to the ſeveral interſections of the parallels, which appears obliquely in *fig.* 38, would be an equinoctial dial, as in *fig.* 39, and the axis perpendicular to it be its ſtyle. An horizontal dial for the latitude of the elevation of the axis might be made, by drawing out the axis and cutting the cylinder, as at *e f g h*, parallel to the horizontal board H; the ſection would be elliptic, as in *fig.* 40. A circle might be deſcribed on the centre, and lines drawn to the diviſions of the ellipſe would be the hour lines; and the wire put in its place again, as E, would be the ſtyle. If this cylinder were cut by a plane perpendicular to the horizontal board H, or to the line S H N, beginning at *g*, the plane of the ſection would be elliptic, as in *fig.* 41, and lines drawn to the points of interſection of the parallels on its edge would be the hour-lines of a vertical direct ſouth dial, which might be made of any ſhape, either circular or ſquare; and F the axis of the cylinder would be its ſtyle. Thus alſo inclining, declining, or reclining dials might be eaſily conſtructed, for any given latitude. Ferguſon, ubi ſupra.

Dialling *Globe*, is an inſtrument made of braſs, or wood, with a plane fitted to the horizon, and an index; particularly contrived to draw all ſorts of dials, and to give a clear exhibition of the principles of that art.

Dialling *Lines*, or *Scales*, are graduated lines, placed on rules, or the edges of quadrants, and other inſtruments, to expedite the conſtruction of dials.

The principal of theſe lines are, 1. A ſcale of ſix hours, which is only a double tangent, or two lines of tangents, each of 45 degrees, joined together in the middle, and equal to the whole line of ſines, with the declination ſet againſt the meridian altitudes in the latitude of London, ſuppoſe, or any place for which it is made: the radius of which line of ſines is equal to the dialling ſcale of ſix hours. 2. A line of latitudes, which is fitted to the hour-ſcale, and is made by this canon: as the radius is to the chord of 90 degrees; ſo are the tangents of each reſpective degree of the line of latitudes to the tangents of other arches: and then the natural ſines of thoſe arches are the numbers, which, taken from a diagonal ſcale of equal parts, will graduate the diviſions of the line of latitude to any radius. The line of hours and latitudes is generally for pricking down all dials with centres. For the method of conſtructing theſe ſcales, ſee Scale. There are ſeveral other lines put upon ſcales for dialling, adapted to particular latitudes. Such are, 1. A line of chords: 2. A line of the ſubſtyle's diſtance from the meridian: 3. A line for the height of the ſtyle above the place: 4. A line of the angle of the hours of 12 and 6: 5. A line of the plane's difference of longitude, or inclination of meridians. All theſe are calculated for every degree of declination, for ſome particular latitude, *e. g.* that of London, by the following problem. Let the latitude of the place and the declination of the plane be given; and let it be propoſed to find the height of the pole above the dial-plane, the diſtance of the ſubſtyle from 12 o'clock, and the plane's difference of longitude. Let N E S W (*fig.* 42.) be the horizon, C its centre, N S the meridian, P the pole, and Z the zenith; H A the declining vertical plane; P 1, P 2, P 3, &c. meridians or ſemi circles, interſecting the circle H A in *t, v*, &c. Let the meridian P *v* 2 be perpendicular to H A, then the plane of the meridian P *v* 2 will be perpendicular to the plane of the dial; and therefore the angle Z P *v* is the plane's difference of longitude, or the angle on the ſphere contained between the meridian of the place and the meridian of the plane, called alſo the "inclination of meridians," and the arc P *v* is the height of the pole above the plane; and the arc Z *v* is the diſtance of the ſubſtyle from the meridian. Therefore in the right-angled ſpherical triangle P Z *v* all the three requiſites will be found. For we have P Z the complement of the latitude, and the angle P Z A the complement of the declination A E; whence will be found P *v*, Z *v*, and the angle Z P *v*. Thus 1. As radius is to the ſine of declination, ſo is the cotangent of latitude to the tangent of the ſubſtyle's diſtance from 12 o'clock; for by a caſe of right-angled ſpherical triangles, rad. : cof. P Z *v* :: tang. P Z : tang. Z *v*. 2. Radius is to the coſine of declination as the coſine of latitude is

to

to the ſine of the ſtyle's height; for by right-angled ſpherical triangles, rad. : S. PZ :: S. PZ v : S. P v. 3. Sine of latitude is to radius as the tangent of declination is to the tangent of the plane's difference of longitude; for, rad. : cof. PZ :: tang. PZ v : cotang. ZP v :: tang. ZP v. cotang. PZ v. 4. For the hour angles, it will be, as radius is to the ſine of the pole's height, ſo is the tangent of the hour-arc from the meridian of the plane to the tangent of the hour angle from the ſubſtyle. For let P t 1 be any hour-circle; and in the triangle P t v, we have the pole's height P v, and the hour-arc, equal to the angle t P v; and therefore to find t v, ſay, rad. : S. P v :: tang. t P v : tang. t v = the angle at the centre, or hour-angle. That theſe ſeveral concluſions are rightly deduced will appear thus. The planes of the two meridians PZ, P v, interſect one another on the ſphere in an angle ZP v, equal to the plane's difference of longitude. And the ſame meridians interſect the plane of the dial in an angle equal to ZV, as it ſhould be. For they interſect one another in the centre of the ſphere, which is the centre of the dial. And they interſect the dial-plane HA in Z and v, and Z v meaſures that angle at the centre. For the ſame reaſon, t v meaſures the hour-angle from the ſubſtyle. Again, P v meaſures the angle of the ſtyle above the ſubſtyle. For P v is perpendicular to HA, and the arc P v meaſures the angle formed at the centre of the ſphere, which is the centre of the dial; one ſide being the axis drawn from P, the other the ſubſtyle drawn from V. Moreover, ZP v has been ſhewn to be the plane's difference of longitude. It appears farther, that the plane's differencce of longitude on the ſphere is converted into the ſubſtyle's diſtance from 12, by the interſection of the two meridians (of the place and of the plane) with the dial-plane: For the angle ZP v expreſſes the one, and the arc Z v the other. Again, every hour-angle on the ſphere is converted into the hour-angle in the dial, by the interſection of the ſame two hour-circles, with the plane of the dial; for the angle t P v expreſſes the hour-angle on the ſphere, and t p the angle at the centre. Similar reſults may be obtained from other data by different proportions. Thus, 1. For finding the ſubſtyle's diſtance: cof. of pole's height above the plane P v: S. lat. or cof. PZ :: radius : cof. of the diſtance of the ſubſtyle from 12. Or, radius: S. declination or cof. PZ v :: tang. of the pole's height above the plane P v : S. of the ſubſtyle's diſtance Z v. 2. For finding the ſtyle's height: cof. of ſubſtyle's diſtance, Z v : S. lat. or cof. PZ :: radius : cof. ſtyle's height P v : or, rad. : S. ſubſtyle's diſtance, Z v :: cotang. declination, or tang. PZ v : tang. of ſtyle's height, P v. 3. For the plane's difference of longitude; cof. lat. or S. PZ : rad. :: S. ſubſtyle's diſtance, Z v : S. plane's difference of longitude, ZP v. Or, rad. : tang. lat. or cotang. PZ :: tang. ſtyle's height, P v : cof. of plane's difference of longitude, ZP v. Or, rad. : cof. declination, S. PZ v :: cof. ſubſtyle's diſtance Z v: cof. of plane's difference of longitude, ZP v. Or, cof. ſtyle's height. P v : S. declination, or cof. PZ v :: rad. : S. of plane's diff. of longitude, ZP v. Or, S. of ſtyle's height P v : rad. :: tang. of ſubſtyle's diſtance, Z v : tang. of plane's diff. of longitude, ZP v. On a ſcale the ſeveral requiſites for any declining dial are had by inſpection. In uſing it count the plane's declination on the line of chords, and a line drawn directly acroſs, will interſect all the other lines in their proper points; which the numbers of graduation will indicate, and theſe give all the requiſites without calculation.

When a ſcale of this ſort is not to be had, the requiſites may be found by Gunter's ſcale, extending upon the ſeveral lines, according to the rules and proportions laid down for that purpoſe.

DIALLING *Sphere*, is an inſtrument made of braſs, with ſeveral ſemi-circles ſliding over one another, on a moving horizon, to demonſtrate the nature of the doctrine of ſpherical triangles, and to give a true idea of the drawing of dials on all manner of planes.

DIALLING, in a *Mine*, called alſo *Plumbing*, is the uſing of a compaſs (which they call dial), and a long line, to know which way the load, or vein of ore inclines, or where to ſhift an air-ſhaft, or bring an adit to a deſired place. See MINING, *art of*, and PLUMBING.

In the ancient books of the Derbyſhire mining laws, directions are given for the practice of dialling, wherein a dial is deſcribed, whoſe circle is divided into 32 points each $= 11\frac{1^\circ}{4}$, and each of theſe into 4 pricks, each $= 2\frac{13^\circ}{16}$. Cary, in the Strand, manufactures dials, or ſquare compaſs boxes, with a ſmall reflector in the lid that turns on an hinge; by means of which, and a pin ſtanding up on the oppoſite ſide of the box, obſervations can be made either to a candle under-ground, or to an object above-ground, and its azimuth conveniently and accurately aſcertained.

DIALOGISM, Διαλογισμος, in *Rhetoric*, is uſed for the ſoliloquy of perſons deliberating with themſelves. We have an inſtance of it in Virgil, where Dido ſays,

> "En quid agam? rurſuſne procos irriſa priores
> Experiar? &c."

In which ſenſe, it is diſtinguiſhed from dialogue. Voſſ. Rhet. lib. v. p. 355. See DIALOGUE.

DIALOGISM is alſo taken in a more extenſive ſenſe for diſcourſe in general, whether held by a perſon alone or in company.

DIALOGUE, a converſation of two or more perſons, real or feigned, either by word or mouth, or in writing. The word is formed from the Latin *dialogus*, of the Greek διαλογος, which ſignifies the ſame.

Dialogue is greatly recommended by many authors, and is the moſt ancient form of writing, and that wherein the firſt authors wrote moſt of their pieces. The archbiſhop of Cambray gives a fine account of the advantages of dialogue, at the head of his paſtoral inſtruction. The ſacred writers, and the fathers, Athanaſius, Baſil, Chryſoſtom, &c. have uſed this mode of inſtruction.

Antiquity made uſe of dialogue, not only on humorous and comical ſubjects, as Lucian did, but alſo on the moſt ſerious and abſtract: ſuch are the dialogues of Plato, and thoſe of Cicero, which turn altogether on ſubjects of philoſophy or politics.

Plato is eminently diſtinguiſhed for the beauty of his dialogues. The ſcenery, and the circumſtances of many of them, are admirably painted. The characters of the ſophiſts, with whom Socrates diſputed, are well drawn: a variety of perſonages is exhibited: we are introduced into a real converſation, often ſupported with much life and ſpirit, after the Socratic manner. For richneſs and beauty of imagination, no philoſophical writer, ancient or modern, is comparable to Plato; the only fault of his imagination is ſuch an exceſs of fertility as allows it ſometimes to obſcure his judgment. It frequently carries him into allegory, fiction, enthuſiaſm, and the airy regions of myſtical theology. The philoſopher is, occaſionally, loſt in the poet. He affords, however, much edification; but whether we be edified with the matter or not, we are always entertained with the manner, and left under a ſtrong impreſſion of the ſublimity of the author's genius.

Cicero's dialogues, or thoſe recitals of converſation which he has introduced into ſeveral of his philoſophical and critical works, are not ſo ſpirited, nor ſo characteriſtical as thoſe of

Plato.

Plato. Yet ſome, as that "De Oratore" eſpecially, are agreeable and well ſupported. They ſhew us converſation carried on among ſome of the principal perſons of ancient Rome, with freedom, good breeding, and dignity. The author of the elegant dialogue "De cauſis corruptæ Eloquentiæ," which is ſometimes annexed to the works of Quintilian, and ſometimes to thoſe of Tacitus, has happily imitated, or perhaps excelled Cicero, in this manner of writing.

Lucian has given us a model of the light and humorous dialogue, which he has carried to great perfection. A character of levity, and at the ſame time of wit and penetration, diſtinguiſhes all his writings. His great object was to expoſe the follies of ſuperſtition, and the pedantry of philoſophy, which prevailed in his age; and he could not have taken any more ſucceſsful method for this purpoſe, than that which he has employed in his dialogues, eſpecially in thoſe of the gods and of the dead, which abound with pleaſantry and ſatire. In this invention of dialogues of the dead, he has been followed by ſeveral modern authors.

Among the moderns, the principal dialogiſts are M. de Fenelon, archbiſhop of Cambray; M. Paſchal, in his Provincial Letters; F. Bouhours, in his Entretiens d'Ariſte, & d'Eugene; M. Fontenelle, in his Dialogues of the Dead, and Plurality of Worlds; Addiſon, Hurd, lord Lyttelton, &c.

Fontenelle's dialogues are ſprightly and agreeable; but his characters are all French, whoever are his perſonages: ſo difficult is it to exhibit characters properly diſtinguiſhed. Hence few authors are eminent for characteriſtical dialogue on grave ſubjects. One of the moſt remarkable in the Engliſh language is

Dr. Henry More, in his Divine Dialogues, relating to the foundations of natural religion. Although his ſtyle be now in ſome meaſure obſolete, and his ſpeakers bemarked with the academic ſtiffneſs of the times in which he lived, yet the dialogue is animated by a variety of character, and a ſprightlineſs of converſation, beyond what are commonly met with in writings of this kind.

Biſhop Berkeley's dialogues, concerning the exiſtence of matter, do not attempt any diſplay of characters; but they furniſh an inſtance of a very abſtract ſubject, rendered clear and intelligible by means of converſation properly managed.

Dialogue writing may be executed, either as direct converſation, where none but the ſpeakers appear, which is the method uſed by Plato; or as the recital of a converſation, where the author himſelf appears, and gives an account of what paſſed in diſcourſe, which is the method generally followed by Cicero. In theſe two methods the form may admit of ſome variation, but the nature of the compoſition is the ſame in both, and ſubject to the ſame laws. A dialogue, in one or other of theſe forms, on ſome philoſophical, moral, or critical ſubject, when it is well conſtructed, ranks high among the works of taſte; but it is more difficult of execution, than writers have generally imagined: for it requires more than merely the introduction of different perſons ſpeaking in ſucceſſion. It ought to be a natural and ſpirited repreſentation of real converſation; exhibiting the character and manners of the ſeveral ſpeakers, and ſuiting to the character of each that peculiarity of thought and expreſſion which diſtinguiſhes him from another. A dialogue, thus conducted, affords the reader a very agreeable entertainment; as by means of the progreſs of the debate among ſeveral perſonages, he receives a fair and full view of both ſides of the argument; and is, at the ſame time, amuſed with polite converſation, and with a diſplay of conſiſtent and well-ſupported characters. An author, poſſeſſing genius for ſuch a kind of compoſition, has it in his power both to inſtruct and to pleaſe. But a compoſition of this ſort is very different from that of many modern writers of dialogues; in which, if we except the outward forms of converſation, and that one ſpeaks and another anſwers, it is altogether the ſame as if the author ſpoke in perſon throughout the whole. Such a mode of writing is frigid and inſipid; it is the form, without the ſpirit of converſation.

A dialogue conſiſts of two parts, an introduction and the body of the diſcourſe. The introduction acquaints us with the place, time, perſons, and occaſion of the converſation. However the introduction ought not to be too long and tedious. Mr. Addiſon complains of this fault: for though, as he ſays, ſome of the fineſt treatiſes of the moſt polite Latin and Greek writers are in dialogue, as many very valuable pieces of French, Italian, and Engliſh appear in the ſame dreſs; yet in ſome of them there is ſo much time taken up in ceremony, that before they enter on their ſubject, the dialogue is half over. (Dial. II. of Med. ap. init.) As to the body of the diſcourſe care ſhould be taken, to keep up a juſtneſs of character in the perſons that are introduced through the whole of the dialogue: and the characters ſhould be ſo diſcriminated, that it may be known from the words themſelves who is the ſpeaker. The principal ſpeaker ſhould appear to be a perſon of great ſenſe and wiſdom, and intimate acquaintance with the ſubject; and he ſhould be capable of fairly anſwering every queſtion that may be aſked, and every objection that may be ſtarted. In the whole diſcourſe, all wrangling, peeviſhneſs, and obſtinacy ſhould be avoided; and nothing appear but good humour and good breeding, with a readineſs to ſubmit to conviction, as evidence preſents itſelf. Cicero has given us two characters of this kind in Craſſus and Antony; from whom Mr. Addiſon ſeems to have taken his Philander and Cynthio, in his "Dialogues upon the Uſefulneſs of Ancient Medals." If younger perſons are introduced, they ſhould rather inquire than diſpute; and neither be too long nor too frequent in the queſtions they propoſe. Sulpitius and Cotta are made to ſuſtain this character by Cicero, and Eugenius by Mr. Addiſon. A perſon of humour may be alſo introduced to enliven the diſcourſe, as Cæſar by Cicero, and Cynthio by Mr. Addiſon. With regard to the ſubject of a dialogue, all the arguments ſhould at leaſt appear probable, and nothing be advanced, which may ſeem weak or trivial. Short and pleaſant digreſſions are allowed, but they ſhould not interrupt the thread of the diſcourſe, and break the union of the parts and conſtant reference to the main end, which are eſſential to a dialogue. The time allowed for a dialogue has been various: Cicero allows two days for his three dialogues concerning an orator; but Mr. Addiſon extends his to three days, allowing a day for each. The method of compoſing dialogues has likewiſe been various: ſometimes a writer relates a diſcourſe by way of narrative, which paſſed between other perſons; ſuch are the dialogues of Cicero and of Mr. Addiſon laſt mentioned: at other times the ſpeakers are introduced in perſon; Cicero's dialogues of "Old Age, of Friendſhip, and of the Parts of Oratory," are written in this manner. Plato and Lucian generally chuſe this method. As for the ſtyle of a dialogue, the low ſtyle is the proper character in which they ſhould generally be written. Ward's Orat. vol. ii. p. 221, &c. Blair's Lectures, vol. iii. p. 61, &c.

Dialogue, in *Muſic*, is a compoſition for at leaſt two voices, or two inſtruments, which anſwer each other; and which frequently uniting at the cloſe, make a trio with the thorough-baſs.

Such are many of the ſcenes in the Italian and French operas.

DIALTHÆA, in *Pharmacy*, is an ointment made (as its name imports) with the althæa or marſh-mallow root. It is now diſuſed.

DIALYSIS, or DIALISIS, in *Grammar*, a character conſiſting of two points ¨ placed over two vowels of a word, which would otherwiſe make a diphthong, but are hereby parted into two ſyllables: as in *Moſaïc*. See DIÆRESIS.

DIAM, in *Geography*, a town of Perſia, in the province of Choraſan; 80 miles N. of Herat.

DIAMANT, LA, a town of the iſland of Martinico, on the ſouth coaſt. N. lat. 14° 26′. W. long. 60° 56′.

DIAMARGARITON, in *Pharmacy*, is an ancient electuary, compoſed of pearls and various aromatics. It is diſuſed or ſuperſeded by the preſent aromatic confection.

DIAMARTYRIA, διαμαρτυρια, in *Antiquity*, a proteſtation that the deceaſed perſon had left an heir, made to hinder the relations from entering upon the eſtate. Potter, Archæol. Græc. tom i. lib. i. cap. 24. p. 128.

DIAMASTIGOSIS. It was a cuſtom among the Lacedæmonians, at the ſolemnization of a feſtival bearing this name, for the children of the moſt diſtinguiſhed families to flaſh and tear each others bodies with rods before the altars of the gods; the fathers and mothers who were preſent at the ſpectacle, animating and exciting them all the while, not to give the leaſt ſign of pain, or concern; though ſome of them were ſo ſeverely laſhed as to die upon the ſpot. Such as were victims to this barbarity were crowned before they were buried, and had ſtatues erected to their honour. They afterwards contented themſelves with whipping their youths till the blood came. During the ceremony the prieſt held in his hand a ſtatue of Diana Orthia. This practice they called diamaſtigoſis, a Greek term derived from διαμαστιγοω, *I whip, ſcourge*. The deſign hereof, apparently, was no other than to harden their youth, and inure them betimes to blows, wounds, &c. that they might deſpiſe them when they came to war.

The cuſtom above deſcribed is ſaid to have had its riſe in conſequence of an oracle, which ordered that the altar of the goddeſs at Sparta ſhould be ſprinkled with blood. Accordingly they offered every year in ſacrifice a man choſen for that purpoſe. This was changed by Lycurgus into the whipping of boys at her altar. But when the boys were whipped to death, it was the moſt cruel method of ſacrificing them; of which Plutarch, in his life of Lycurgus, declares he had ſeen ſeveral inſtances. Dacier, in his notes on Plutarch's life of Themiſtocles, obſerves, that in one of the towns of Arcadia, they uſed to whip the women, as they did the young men or boys round Diana's altar at Sparta; and Potter, in his Greek antiquities, ſays, that Bacchus had an altar in Arcadia, upon which a great many young damſels were beaten to death with rods.

DIAMBRA, in *Pharmacy*, is an electuary of the older pharmacopœias, into which ambergris entered as an ingredient, and is now diſuſed.

DIAMETER, from δια and μετρειν, *to meaſure*, in *Geometry*, a right line paſſing through the centre of a circle and terminated on each ſide by its circumference.

Or, the diameter may be defined a chord paſſing through the centre of a circle. Such is the line AE (*Plate* IV. *Geometry*, *fig.* 78.) paſſing through the centre C. Hence the diameter is the greateſt of all chords, and therefore a line greater than the diameter, drawn from any point within the circle, will cut the circumference. Hence it appears that a line, equal to a given line, leſs than the diameter of the circle, may be applied, or inſcribed in a given circle. Hence alſo it appears, that if, to the circumference of a circle AFEB, (*fig.* 79.) from any point D, which is not the centre, right lines DA, DF, DE be drawn, the greateſt of all, DA, will be that which paſſes through the centre C; and of the reſt, that DF, whoſe other extreme, F, is placed neareſt in the circumference to the extreme, A, of the greateſt, will exceed any other, DE, whoſe extreme, E, is at a greater diſtance. For, from the centre C, draw CE and CF. 1. AD = DC + CF ⌐ DF. 2. Since DC is common, CF = CE, and DCF ⌐ DCE. Therefore DF is ⌐ DE. Whence it follows, that as no two lines, DE, DF, drawn from D, on the ſame ſide of the diameter, AB, can be equal to each other, three equal right lines cannot poſſibly be drawn from the periphery to any point, beſides the centre of the circle; and, therefore, if from a point in any circle, three equal right lines can be drawn to the periphery, that point is the centre of the circle. Moreover, no circle can be deſcribed to cut another in more points than two; for if it were poſſible to cut it in three points, G, E, F, then right lines drawn from the centre, Q, to thoſe points would be all equal, which is impoſſible, unleſs when the centre Q coincides with C: and then the circles themſelves will neither cut, nor touch, but coincide, and become one circle.

Half a diameter, as CD, (*fig.* 78.) drawn from the centre C, to the circumference, is called the ſemidiameter, or radius.

The diameter divides the circumference into equal parts. And hence we have a method of deſcribing a ſemicircle upon any line; aſſuming a point therein for the centre.

To find the ratio of the DIAMETER *to the circumference.*—This has been greatly ſought for by the mathematicians; and no wonder; inaſmuch as if this were juſtly given, the quadrature of the circle were atchieved.

Archimedes firſt propoſed a method of finding it, by regular polygons inſcribed in a circle, till arriving at a ſide ſubtending an exceeding ſmall arc, and then ſeeking a ſide of a ſimilar polygon circumſcribed; each of theſe being multiplied by the number of ſides of the polygon, give the perimeter of the polygon both inſcribed and circumſcribed. In which caſe the ratio of the diameter to the circumference of the circle is greater than that of the ſame diameter to the perimeter of the circumſcribed polygon, but leſs than that of the diameter to the perimeter of the polygon inſcribed. The difference between both gives the ratio of the diameter to the circumference in numbers nearly true. See CIRCLE, art. 23.

That celebrated author, as already obſerved, by polygons of 96 ſides, found the ratio of the diameter to the circumference to be as 7 to 22; *viz.* ſuppoſing the diameter 1, the perimeter of the inſcribed polygon is found $3\frac{10}{71}$, and that of the circumſcribed $3\frac{1}{7}$.

After this example, later authors have found out ratios yet nearer truth; Wolfius finds it as 1000000000000000 to 3141592653589793 2; but none ſpent ſo much time on it as Van Ceulen, who, after immenſe pains, found that ſuppoſing the diameter, 1, the circumferenee is leſs than 3.14159265358979323846264338387950, and yet greater than the ſame number with only the laſt figure 0 changed into 1. Mr. A. Sharp doubled Van Ceulen's numbers; and this is ſo near the truth, that the diameter of the earth being given, we might from thence compute the number of ſands equal to the ſolid contents of the earth ſo near as not to differ one grain of ſand from the truth. Mr. Machin carried them to one hundred places; thus the circumference of a circle whoſe diameter is 1, will be 3.14159265358979 32384626433838795028841971693993751058209749445 92307816405286208998628034825342117067 9.

But as ſuch prolix numbers are too unwieldy for practice, many of our preſent practical geometricians aſſume the diameter to be to the circumference as 100 to 314; or in

greater circles as 10000 to 31415; in which proportion Ptolemy, Vieta, and Huygens, agree with Van Ceulen. Ad. Metius gives us the ratio 113 to 355, which is the moſt accurate of all thoſe expreſſed in ſmall numbers; as not erring 3 in 10000000. Thoſe in common uſe are Archimedes's, Metius's, or the proportion of 1 to 3.14159.

The DIAMETER *of a circle being given, to find the circumference and area; and the circumference being given, to find the diameter.*—The ratio of the diameter to the circumference being had, as in the laſt article, that of the circumference to the diameter is had likewiſe. Then the circumference being multiplied into the fourth part of the diameter, gives the area of the circle. Thus, if the diameter be 100, the circumference will be 314, and the area of the circle 7850. But the ſquare of the diameter is 10000: therefore, this is to the area of the circle as 10000 to 7850, that is, as 1000 to 785 nearly.

The area of the circle being given, to find the DIAMETER.—To 785, 1000, and the given area of the circle 246176, find a fourth proportional, *viz.* 3113600, which is the ſquare of the diameter. Out of this extract the ſquare root, and it is the diameter itſelf.

DIAMETER *of a conic ſection*, is a right line biſecting all the ordinates, &c. See CONIC *Sections*.

This, when it cuts the ſaid lines at right angles, is more particularly called the *axis of the curve*, or *ſection*.

DIAMETER, *Tranſverſe*, is a right line, which being continued each way between two curves, biſects parallel right lines between the ſame.

DIAMETER, *Conjugate*, is a right line, biſecting lines drawn parallel to the tranſverſe diameter. See CONJUGATE.

DIAMETER *of any Curve*, is a right line which divides two other parallel right lines, ſo that in each of them, all the ſegments or ordinates on one ſide, between the diameter and different points of the curve, are equal to each other. This is Newton's ſenſe of a diameter. But, according to ſome, a diameter is that line, whether right or curved, which biſects all the parallels drawn from one point to another of a curve. In this way every curve will have a diameter; and hence the curves of the *ſecond* order, have, all of them, either a right-lined diameter, or elſe the curves of ſome one of the conic ſections for diameters. And many geometrical curves of the higher orders may alſo have for diameters, curves of theſe inferior orders.

DIAMETER *of a ſphere*, is the diameter of the ſemicircle by whoſe rotation the ſphere is generated; called alſo the axis of the ſphere.

DIAMETER *of gravity*, is a right line paſſing through the centre of gravity.

DIAMETER, in *Aſtronomy*, is either apparent or real. The apparent diameter of a heavenly body, is the angle which it ſubtends at the place of the obſerver, and it varies inverſely as the diſtance, becauſe ſmall angles are proportional to their tangents.

It is by obſervations of the apparent diameters of the planets, that we are enabled to aſcertain their true diameters, or real magnitudes, having previouſly found their diſtance. See DISTANCE.

In the triangle T A B, (*Plate* IX. *Aſtronomy. fig.* 64) in which the angle B is a right angle, we have this proportion:

R : ſin. A T B :: T A : A B;

thus the true diameter A B is found by multiplying the diſtance T A by the ſine of the angle A T B, which is the apparent diameter of the planet.

The apparent diameter of the ſun is continually changing, and the law of its variation affords a ſtrong proof of the elliptic nature of the earth's orbit, and that the motion of the earth is really ſlower, as its diſtance from the ſun is greater. For the diameter of the ſun is about 31′ 31″ in ſummer, and 32′ 36″ in winter; from which it is evident, that its diſtance in ſummer is to its diſtance in winter, as 32′ 36″ to 31′ 31″. The hourly motion of the ſun in winter is 2′ 33″; and 32′ 36″ : 31′ 31″ : : 2′ 33″ : 2′ 28″. Therefore, the hourly motion in ſummer would be 2′ 28″, if it was really uniform, and its apparent variation occaſioned only by our greater or leſs diſtance from the ſun. But by obſervation, the hourly motion in ſummer is only found to be 2′ 23″: ſo that beſides the diminution of 5″, cauſed by the increaſe of diſtance, there is a farther dimunition of 5″, which can only be attributed to a decreaſe of velocity in the motion of the earth.

It is only ſince the application of teleſcopes to aſtronomical inſtruments that the diameters of the ſun and planets have been accurately determined.

There are ſeveral methods of determining the diameter of the ſun: By micrometers; by obſerving the time of its paſſage over the meridian wire of a tranſit inſtrument; by the difference of altitude between its upper and lower limb, as obſerved by a mural quadrant or good circular inſtrument, or by a repeating circle.

The meaſurements which uſually have been conſidered as the beſt, and which have been adopted in our ſolar tables, have been made with object-glaſs micrometers. De la Lande, in the year 1760, determined the diameter (apogee) 31′ 30½″. Dr. Maſkelyne 31′ 29″.2. Short, with an object-glaſs micrometer, applied to a two foot teleſcope, 31′ 28″. There is neceſſarily ſome ſmall uncertainty in the meaſure by a micrometer from the difficulty of obtaining the accurate value of its ſcale of diviſions. Some ſmall difference will likewiſe ariſe from the nature of the teleſcope employed.

A good aſtronomical circle, moving eaſily in azimuth, would be well adapted for this determination; as ſeveral obſervations might be made before and after the meridian paſſage, and the correction for change of altitude, applied by the table calculated for that purpoſe, and which we have given under DECLINATION.

Perhaps the repeating circle of Borda would be ſtill preferable. Of the extreme accuracy that may be obtained by repeating the angle, even with a ſmall inſtrument, we may form ſome idea from a ſeries of obſervations, made by M. Quenot, and inſerted in the Connaiſſance des Temps for the year 1803. He repeated the meaſure of the diameter of the ſun a thouſand times, and the obſervations divided into ten parts of one hundred each, were as follows:

52° 32′ 30″	Diameter (apogee) deduced	31′ 31″.5
52 30	———————	31 30
52 33	———————	31 31 8
33	———————	31 31 8
31	———————	31 30.6
33	———————	31 31 8
29	———————	31 29.4
30 30	———————	31 30.3
34 30	———————	31 32.7
30	———————	31 30

Mean 31′ 31″.

The inſtrument uſed was a reflecting circle of Borda of 5 inches radius.

This quantity is the ſame as is adopted by Delambre in his ſolar tables lately publiſhed. Annexed to this article is a table of the ſun's ſemidiameter to every degree of mean anomaly. The variation in the apparent ſemidiameter of the ſun correſponds with the variation of the ſun's horizontal parallax, which is, in fact, the apparent ſemidiameter of the earth, as ſeen from the ſun; they of courſe increaſe and decreaſe together, and inverſely as the diſtance of the two

bodies from each other, as appears from the ſame table, in which the parallax is likewiſe given.

If we examine the meaſures that have been given by different aſtronomers, of the diameter of the ſun, it will be found that they have a tendency to diminiſh as they approach the preſent time; a ſuſpicion has hence ariſen that the ſun may poſſibly be decreaſing in magnitude. But this is ſo highly improbable, that we are inclined to attribute the circumſtance partly to accident and partly to the improvement of teleſcopes, which render the apparent image of the ſun ſomewhat ſmaller.

The difference between the greateſt and leaſt diameters of the ſun is 64.″6.

The ſemidiameter of the ſun, divided by the correſponding parallax, (table I.) gives a conſtant quantity, which expreſſes the ratio of the diameters of the ſun and the earth.

Thus, $\frac{16' 1''.1}{8.'8} = 109.2$.

According to De la Lande, who aſſumes the ſun's horizontal parallax, 8″.6; the ſun's diameter is to that of the earth as 111 : 1.

From which it appears, that if the centre of the ſun be ſuppoſed placed in the ſame point as the centre of the earth, the globe of the ſun would then extend to a diſtance nearly twice as great as the orbit of the moon.

In calculations of eclipſes, it is uſual to diminiſh the diameter of the ſun 5″ or 6″, to allow for the irradiation, which makes the apparent diſk of the ſun appear greater than it otherwiſe would do.

The apparent diameter of the moon varies from 29′ 22″ to 33′ 34″: its mean diameter being nearly equal to the leaſt apparent diameter of the ſun.

The variations in the diameter of the moon are much greater than in the diameter of the ſun, as it is in ſome meaſure affected by almoſt all the lunar irregularities.

Theſe variations indicate a correſponding change in her diſtance. Horrox, as long ſince as the year 1638, obſerved, that the moon being apogee, was not always at the ſame diſtance from the earth, that the diameter was leaſt in the conjunctions apogee, and greateſt in the ſyzigies perigee.

When the argument of the evection is O ſigns, the diameter is diminiſhed 18″ or 20″; but when the argument of evection is VI ſigns, it is, on the contrary, augmented by the ſame quantity, though its diſtance from the apogee ſhould, in both caſes, be the ſame. In the ſame manner with reſpect to the argument of the variation, when that is O or VI ſigns, the diameter of the moon increaſes 14″ or 15″; and when the argument is III or IX ſigns; it decreaſes by the ſame quantity, though at the ſame diſtance from the apogee. See EVECTION and VARIATION.

The expreſſion for the diameter of the moon for any given time is nearly this:

31.′ 7.″3 − 1.42.″3 cof. anomal + 5.″4 cof. 2 anomal. + 13.″7 cof. 2 diſt. ☽ ⊙ − 20.″2 cof. (2 diſt. ☾ ⊙ − anomal ☽) the other equations are ſcarcely ſenſible; but they may be included by taking the equatorial parallax as an argument for the ſemidiameter, as in the new lunar tables, by Burg, publiſhed by the Bureau des Longitudes, at Paris.

As the moon approaches the zenith, her diſtance becomes leſs, and the apparent diameter is increaſed. Let T (*fig.* 65.) be the centre of the earth, O the place of an obſerver on the ſurface, Z the moon ſuppoſed to be in the zenith. The diſtance Z O is about $\frac{1}{60}$ part leſs than the diſtance Z T; its diameter, therefore, ſeen from O, will be greater than if ſeen from T in the ſame proportion.

If the moon be at L, its zenith diſtance being the angle L O Z, the diſtance L O will be evidently leſs than the diſtance L T. When the moon is at the horizon at H, the augmentation will be nearly inſenſible, for which reaſon we conſider the horizontal ſemi-diameter as equal to that which would be ſeen from the centre of the earth; but this is not quite correct, for the moon muſt be below the horizon, by a quantity equal to half her parallax, for the augmentation to be really equal O; that is when the triangle L O T is iſoſceles.

When the horizontal diameter of the moon is known, it is eaſy to compute the augmented diameter, ſince they are to each other as L O to L T.

In the triangle L O T, the angle O is the ſupplement to the apparent zenith diſtance; the angle L T O is the true zenith diſtance, as ſeen from the centre of the earth: and L O : L T :: ſine O T L : ſin. L O T or L O Z. Therefore, the horizontal diameter is to the apparent diameter, as the ſine of the true zenith diſtance of the moon, as ſeen from the centre of the earth, is to the apparent diſtance, as ſeen from the point O. The augmented diameter of the moon may be found, therefore, by this proportion.

As cof. of true altitude is to cof. of apparent altitude, ſo is the horizontal diameter to the augmented diameter. The difference between the two is called the augmentation of the moon's diameter; a table of which has been given under DECLINATION.

In the above computation, if the moon is very near the zenith, her diſtance from the centre and ſurface of the earth ſhould be employed inſtead of the zenith diſtances.

The diameter of the moon may be meaſured in the ſame manner as that of the ſun, or it may be inferred with great accuracy, from the time which elapſes between the immerſion and emerſion of a fixed ſtar. M. Burg, who computed it by this latter method for his lunar tables, found no difference from the reſult, by an object glaſs micrometer of Dollond.

The apparent diameters of the planets, at leaſt of thoſe near to us, vary much more than the diameters of the ſun and moon.

The diameter of a planet, when its diſtance is equal to the mean diſtance of the ſun, being divided by the diſtance of the planet from the earth, gives its actual or apparent diameter as ſeen from the earth; and the diſtance is found by this proportion: As the ſine of the elongation, is to the ſine of the commutation, ſo is the diſtance of the planet from the ſun reduced to the ecliptic, to the diſtance from the earth in the plane of the ecliptic. This diſtance divided by the geocentric latitude, is the diſtance of the planet from the earth.

The moſt favourable opportunity of obſerving the diameter of Mercury is when he paſſes over the diſc of the ſun. It may either be meaſured directly by a micrometer, or computed by the time it takes to paſs over the edge of the ſun.

De la Lande meaſured the diameter of Mercury on the ſun's diſc, in 1753, with an object glaſs micrometer adapted to a teleſcope of 18 feet, and found it 11.″8. At that time the diſtance of Mercury to the earth, was to the mean diſtance of the ſun to the earth, as 55674 to 101007.

Therefore, 1010 : 557 :: 11.″8 :: 6.″5.

Hence, 6.″5 is the diameter of Mercury, at a diſtance equal to the mean diſtance of the ſun.

Dr. Bradley, by a ſimilar method, with a teleſcope of 120 feet, in 1723, found the diameter on the ſun's diſc 10″.7, which gives 7.″3 for the mean diſtance. By computing it from the time it took to quit the diſc, De la Lande found 5.″9.

The diameter of Venus is found in the ſame manner, and with extreme accuracy, for every ſecond of the diameter of Venus employs 19″ to quit the diſc of ſun. And as it is not eaſy to miſtake 5″ in the length of time the planet takes

to

to quit the disc, the diameter of Venus may be known to a quarter of a second.

When the second limb of the planet touches the exterior limb of the sun in E, (*fig.* 66.) Venus is at the point F in her orbit, and the distance C E of the centres of the planet and the sun, is equal to the sum of their semi-diameters; on the contrary, in the interior contact, Venus is at D, and the distance of their centres is equal to the difference of their semi-diameter.

The shortest distance C B is supposed known; therefore, by resolving separately the two triangles, C B D, C B F, we obtain the two portions of the planet's orbit B D, B F: their difference D F gives the length of time the planet should employ to quit the disc, as observed from the centre of the earth. Proper allowance being made for parallax, the transit in 1761 gave 57."9, and that of 1769, 57."2. according to De la Lande. See TRANSIT *of Venus* and PARALLAX.

Picard measured the diameter of Mars on the 8th Sept. 1762, and it appeared to him to be 30". This observation reduced to the mean distance of the sun from the earth, is equal 11."4; according to Monnier, 9."9; by Rochon, with a prismatic micrometer, 8."9.

The diameter of Mars was very acurately determined by Dr. Herschel, in 1783 (Philos. Trans. 1784). He estimates the diameter 8."94, and the difference of $\frac{1}{16}$ between the equatorial and polar diameter. This supposes the planet's distance equal to the mean distance from the sun.

The diameter of Jupiter was observed in the year 1719, by Pound, with a micrometer applied to a telescope of 123 feet. He found it always between 38" and 40"; generally 39". By the length of time which the first and third satellite employed to pass over the disc, observed with the same telescope, Newton computed its diameter $27\frac{1}{4}$" at its mean distance: this would give 3' $13\frac{3}{4}$", at the distance of the sun from the earth.

But astronomers prefer a direct measure by a micrometer.

The equatorial diameter of Jupiter is found to exceed the polar diameter, in the proportion of 1.073 : 1.

The diameter of Saturn, observed by Pound, was 18", and the diameter of the ring 42".

Dr. Herschel, from a mean of a great many measures of the larger ring, makes it 46".67, at the mean distance of Saturn.

The dimensions of the two rings are in the following proportions:

	Parts.
1. Inside diameter of the smaller ring	5900
2. Outside diameter	7510
3. Inside diameter of the larger ring	7740
4. Outside diameter	8300
5. Breadth of the inner ring	805
6. Breadth of the outer ring	280
7. Breadth of the space between the rings	115

which may be thus expressed in English miles:

1.	146,345
2.	184,393
3.	190,248
4.	204,883
5.	20,000
6.	7,200
7.	2,839

The diameter of the planet, at its mean distance, is 1.8"

A great difference of opinion exists, relative to the apparent diameters of the new planets, Ceres, Pallas, Juno, and Vesta.—According to Dr. Herschel, none of their diameters subtend an angle of half a second, at the distance of the earth from the sun, but Mr. Schroeter estimates Ceres at 3" 5, and Pallas 4".5.

The diameters of Jupiter's satellites have been estimated by the time they employ to enter the shadow of the planet.

According to Bailly, they subtend the following angles, as seen from Jupiter.

I.	60' 26"
II.	29 42
III.	22 28
IV.	9 39

Mr. Schroeter, who has made a great number of observations on the satellites of Jupiter, with a view of ascertaining their diameters, objects to the method of Bailly, and prefers employing the time which the satellites take to disappear behind the body of the planet, or to enter on the disc when they pass over it. This method, with a telescope of high power, seems capable of great exactness. The result of M. Schroeter's observations is as follows.

	I.	II.	III.	IV.
Time employed to enter the disk	235"	245".3	544".5	505
Diameters seen from Jupiter	33' 16"	17' 13"	18' 59"	7'.32"
True diameters in miles 15 to a degree	564	465	818	570
In miles 60 to a degree	2256	1860	3272	2280
In proportional parts of diam. of 24	$\frac{1}{34}$	$\frac{1}{42}$	$\frac{1}{24}$	$\frac{1}{34}$
Diameter viewed from the earth. 24 perigee	1.403	1.15	2.04	1.42
The same by direct measurement	1.39	1.09	2.27	1.41
By direct measure of the shadow	1.01	0 91	1.88	——
Diam. at the mean dist. of earth from ⊙, that of Jupiter being 3'13".5	5.53	4 54	8.05	5.60
Diameters. Jupiter being supposed 1	0.0288	0.0238	0.0418	0 0291

They do not appear to differ much in magnitude from each other, they are about $\frac{1}{20}$th of the diameter of Jupiter, or nearly one half of the diameter of the earth.

Diameters of the sun, moon, and planets, according to different astronomers.

DIAMETER *of a Column*, is its thickneſs juſt above the baſe. From this the module is taken, which meaſures all the other parts of the column.

DIAMETER *of the Diminution*, is that taken from the top of the ſhaft. See DIMINUTION.

DIAMETER *of the Swelling*, is that taken at the height of one-third from the baſe.

DIAMINTZ, or DUNAMUND, in *Geography*, a town of Ruſſia, in the government of Riga, on the coaſt of the Baltic; 12 miles N. W. of Riga.

DIAMIUM, in *Ancient Geography*, *Gianutti*, an iſland of Italy, in the vicinity of that of Igillium.

DIAMOND; *Diamant*, Fr.; *demant*, Germ.; adamas *of ancient authors*.

The diamond has from the remoteſt antiquity been conſidered as the moſt valuable or more properly, the moſt coſtly ſubſtance in nature. The reaſon of the high eſteem in which it was held by the ancients, was its rarity and its extreme hardneſs; for, the art of cutting and poliſhing this gem, not having been then invented, its ſuperior brilliancy and luſtre could not be duly appreciated. The ſhort account which Pliny (Hiſt. Nat. lib. 37. § 15.) gives of this ſubſtance, contains more error than truth: we ſhall, however, commence our article by a detail of theſe particulars, as they conſtitute the whole of the information handed down to us by the ancients concerning this, the moſt precious of all the productions of art or nature.

The diamond, ſays Pliny, is the moſt coſtly of human poſſeſſions:

poſſeſſions: it was found diſſeminated like gold, through metallic veins; but was of very rare occurrence, and was always accompanied by gold. The moſt ancient writers deſcribe it as found only in Ethiopia, between the iſland Meroe and the temple of Mercury; and as reſembling a cucumber ſeed both in ſhape, ſize, and colour. It has of late, continues the ſame author, been brought from India. The Indian diamond is not found in gold mines, and appears to have ſome relation to rock-cryſtal, ſince it reſembles this ſubſtance in its colourleſs tranſparency, and in its form, which is either that of a ſmooth ſix-ſided priſm, terminated in a point on one extremity, or of two pyramids united by their baſes. Its magnitude is ſometimes equal to that of a hazel nut. The Arabian diamond reſembles the above, only it is ſmaller. The diamond is diſtinguiſhed from all other ſubſtances by its hardneſs, which is ſuch as to break and ſplinter both the hammer with which it is ſtruck, and the anvil on which it lies. It is incapable alſo of being heated by the moſt violent fire: on both which accounts it is called by the Greeks *adamas*, that is, unconquerable. But though it reſiſts the action of fire and ſteel, yet if macerated in the freſh blood of a he-goat, it may, with difficulty, be ſplit by a hammer. The ſmall ſhivers thus obtained are much ſought after by engravers on gems; for when ſet in an an iron handle, they enable the artiſt readily to cut the hardeſt ſtones. A kind of antipathy ſubſiſts between the diamond and magnet, ſo that the latter cannot attract iron when in contact with the former. The diamond alſo deſtroys the effect of poiſons, and cures inſanity, on which account it is called by ſome *anachitis*. So far concerning the knowledge poſſeſſed by the ancients of this gem.

When the Arabians, during the dark ages of Europe, had eſtabliſhed themſelves in Spain, and on the ſouthern and eaſtern coaſts of the Mediterranean ſea, the wild and monſtrous fictions of theſe and other oriental nations, obtained a currency in Europe, which even at preſent has not entirely ceaſed. Among other abſurdities, the occult qualities and ſuperſtitious uſes of the gems was adopted with peculiar eagerneſs, and, no doubt, contributed greatly to the high eſtimation in which theſe ſubſtances were held. The diamond, as being the moſt valuable and beautiful of the gems, was ſuppoſed to be endowed with theſe hidden virtues in the higheſt degree: hence it was held as an infallible ſpecific in many diſeaſes, a teſt of conjugal fidelity, a reconciler of domeſtic ſtrife, and an amulet of higheſt power againſt poiſons, inſanity, witchcraft, incantations, nocturnal goblins, and evil ſpirits.

At length, after a long night of intellectual darkneſs, men began to be convinced, that the beſt way of acquiring a knowledge of the properties of natural ſubſtances, was by an inveſtigation of facts, inſtead of appealing to the fancy. Yet it was a long time before the falſe facts and idle fancies concerning the gems in general, and the diamond in particular, began to give way to experiment and common ſenſe; for Rulandus in his "Lexicon Alchemiæ," firſt publiſhed in 1607, gives an account of the diamond, even more incorrect than that which Pliny has left us. Two years after this period, however, namely, in 1609, Boetius de Boot publiſhed his valuable treatiſe "De Lapidibus et Gemmis," in which is contained a detailed account of all that was previouſly known or imagined concerning the diamond, and accompanied by his own obſervations and remarks. The whole article is too long to be tranſlated and inſerted in this place, but is well worthy of peruſal as a very curious ſpecimen of the method employed by men of real candour and underſtanding in treating of thoſe ſubjects of natural hiſtory, that were as yet not wholly emancipated from the influence of ſuperſtition. He firſt obſerves, that the diamond is diſtinguiſhed from other gems by the ſuperior luſtre which it exhibits, when fixed in a plate of black maſtich, and the force with which they adhere to each other. This he attributes to a kind of affinity between theſe two ſubſtances; from which circumſtance, and becauſe the diamond, when heated, attracts ſmall ſtraws, &c. as amber does, he concludes that this gem differs from the others, in being of an inflammable, ſulphureous, and oily nature. From this circumſtance, certain modern writers have claimed for De Boot the honour of being the firſt who has maintained the inflammability of the diamond. There is ſurely however a great difference between arriving at truth by means of falſe or true premiſes. Romé de Liſle, who made the experiment with great care, affirms, that rock cryſtal adheres to maſtich with at leaſt as much firmneſs as the diamond does; and it is a fact perfectly well aſcertained, that tourmaline, and many other mineral bodies, that are well known to contain no inflammable matter in their compoſition, will, when warmed or rubbed, attract various light bodies; ſo that the facts adduced by De Boot do not juſtify his concluſion. Newton, on the other hand, ſuſpected the inflammability of the diamond, becauſe in its power of refracting light, it differed greatly from all earthly bodies, and obviouſly ranked in this reſpect among the inflammable ones; an obſervation which all ſubſequent experience has only ſerved to confirm.

But though De Boot has fallen into the error above-mentioned, it ſhould be remarked to the credit of his account of the diamond, that he points out with conſiderable exactneſs the diamond mines of India and Malacca, and is much inclined to doubt the genuineneſs of all the diamonds ſaid to be found in Europe. He diſproves, from experiment, the aſſertions of Pliny reſpecting the impoſſibility of breaking this ſubſtance; and alſo ſhews, that it exerciſes no power over the property of attracting iron, poſſeſſed by the magnet. With regard to the ſuperſtitious and metaphyſical properties of the diamond, though he does not venture to deny them altogether, yet he maintains that they are not to be attributed to the gem itſelf, but to the angelic ſpirits, which it has pleaſed the Almighty to connect in a myſterious manner with certain natural ſubſtances.

The ſubſequent hiſtory of diſcoveries reſpecting the diamond, relates for the moſt part to its combuſtibility; and theſe the reader will find ſufficiently detailed in the article CARBON. We ſhall therefore proceed to the deſcription of this gem, according to the moſt accurate modern writers on the ſubject.

The diamond is either colourleſs, or of a light yellow, or ſmoke-grey paſſing into bluiſh, or pearl-grey, or clear wine-colour; on one hand deepening into clove-brown, and on the other into yellowiſh-green: it alſo occurs of a deep, almoſt black brown, Pruſſian blue, or roſe red. The colourleſs varieties are the moſt eſteemed, and next to theſe in value are the blue, red and black; the light coloured are the leaſt in eſtimation.

It is found cryſtallized in the regular octohedron (which is its primitive form) compoſed of two four ſided pyramids, applied baſe to baſe, or in the cuneiform octohedron. Sometimes each triangular face of the primitive octohedron is replaced by ſix ſecondary triangles, bounded by curvilinear lines; in which caſe the whole cryſtal has forty eight faces, and is of a ſpheroidal figure. Other ſpheroidal varieties of this mineral are the dodecahedron, a ſolid of twenty four faces, and a compreſſed ſpheroid reſembling a very ſhort hexahedral priſm, terminated by very ſhort curvilinear pyramids.

The ſurface of the natural cryſtals, eſpecially the ſpheroidal, is ſomewhat dull and chatoyant. This appearance which is generally repreſented as the effect of a thin cruſt, appears to be cauſed merely by the ſaliant edges of the laminæ of which the cryſtal conſiſts. When its ſurfaces are reduced to perfect ſmoothneſs by grinding and poliſhing, the diamond is of extreme brilliancy, far ſurpaſſing every other ſubſtance in luſtre, and the lively play of priſmatic colours, which dart from it in lines of light, whenever its poſition, with regard to the eye, undergoes the leaſt variation. The fracture of the diamond is ſtraight foliated; hence it may readily be cleft in the direction of its lamellæ by a dextrous artiſt. Some of the ſpheroidal varieties, however, are compoſed of curved plates; theſe are of intenſe hardneſs, and cannot be either ſplit, or very highly poliſhed; they are therefore uſed by the glaziers and engravers on gems, or are ground into a powder, and employed in the poliſhing of other diamonds.

The hardneſs of this gem is ſuperior to that of all other bodies; it yields however to corundum by long-continued friction. It is brittle and frangible without much difficulty. Its ſp. gr. varies from 3.518 to 3.550.

Diamond, even when rough, acquires by friction the vitreous or poſitive electricity. It becomes phoſphoreſcent when expoſed either to the entire rays of the ſun, or to the blue ones alone, when ſeparated by the priſm, and concentrated on the diamond by means of a lens. A ſimilar effect is alſo produced by fixing it to the end of a charged conductor, and taking a few electric ſparks from it. Many diamonds, however, are incapable of becoming phoſphoreſcent, although agreeing in colour, tranſparency, &c. with thoſe which readily become luminous. The ſmaller acquire this property by a much ſhorter expoſure to the light, than the larger ones do; ſometimes a diamond that is not phoſphoreſcent, by the mere action of the ſolar rays, may be made ſo, by previouſly immerſing it for ſome time in melted borax. See Groſſer in Journ. de Phyſique, vol. xx. p. 270.

Diamond, when heated to the temperature of melting copper, and expoſed to a current of air, is gradually, but completely combuſtible; it is ſurrounded by a luminous areola during the proceſs. It is wholly converted into carbonic acid, and therefore conſiſts of pure carbon, as we have already mentioned under that article.

The art of cutting and poliſhing diamonds was probably known to the artiſts of Hindooſtan and China at a very early period: but the only material uſed in the Eaſt for this purpoſe being corundum, and the apparatus being of extreme ſimplicity, the jewellers of theſe countries are incapable of bringing out the peculiar beauty of the diamond in a degree at all comparable to what is readily effected by European artiſts. The extreme hardneſs of this gem had baffled the attempts of the jewellers of Europe till the year 1456, when a young man, named Louis Berghen, a native of Bruges, endeavoured to poliſh two diamonds, by rubbing them againſt each other: he found that by this means a facet was produced on the ſurface of the diamonds, and in conſequence of this hint, conſtructed a poliſhing wheel, on which, by means of diamond powder, he was enabled to cut and poliſh this ſubſtance, in the ſame way as other gems are wrought by emery. Previouſly to this diſcovery, diamonds were ſet in jewellery, preciſely in the ſtate in which they arrived from India, and hence the octohedrons were much more eſteemed than the reſt, both on account of the regularity of their figure and the ſuperiority of their poliſh.

On the ſubject of the manufacture of diamonds, we ſhall ſtate the following particulars, on the authority of Jeffries's treatiſe of Diamonds.

Diamonds are cut and manufactured by jewellers into brilliants and roſe diamonds; the former being for the moſt part made out of the octohedral cryſtals, and the latter from the ſpheroidal varieties. To faſhion a rough diamond into a brilliant, the firſt ſtep is to modify the faces of the original octohedron, ſo that the plane formed by the junction of the two pyramids ſhall be an exact ſquare, and the axis of the cryſtal preciſely twice the length of one of the ſides of the ſquare. The octohedron being thus rectified, a ſection is to be made, parallel to the common baſe, or *girdle*, ſo as to cut off $\frac{5}{18}$ths of the whole height from the upper pyramid, and $\frac{1}{18}$th from the lower one. The ſuperior and larger plane, thus produced, is called the *table*, and the inferior and ſmaller one is named the *collet*: in this ſtate it is called a *compleat ſquare table diamond*. To convert it into a brilliant, two triangular facets are placed on each ſide of the table, thus changing it from a ſquare to an octagon; a lozenge-ſhaped facet is alſo placed at each of the four corners of the table, and another lozenge extending lengthways along the whole of each ſide of the original ſquare of the table, which, with two triangular facets ſet on the baſe of each lozenge, compleats the whole number of facets on the table-ſide of the diamond: *viz.* eight lozenges and twenty-four triangles. On the collet-ſide are formed four irregular pentagons, alternating with as many irregular lozenges radiating from the collet as a centre, and bordered by ſixteen triangular facets adjoining the girdle. The brilliant, being thus compleated, is ſet with the table-ſide upwards, and the collet-ſide implanted in the cavity made to receive the diamond.

The regular roſe diamond is formed by inſcribing a regular octagon in the centre of the table-ſide of the ſtone, and bordering it by eight right-angled triangles, the baſes of which correſpond with the ſides of the octagon; beyond theſe is a chain of eight trapeziums, and another of ſixteen triangles. The collet-ſide alſo conſiſts of a minute central octagon, from every angle of which proceeds a ray to the edge of the girdle, forming the whole ſurface into eight trapeziums, each of which is again ſub-divided by a ſaliant angle (the apex of which touches the girdle,) into one irregular pentagon, and two triangles.

In the formation of either a brilliant or roſe-diamond of regular proportions, ſo much is cut away, that the weight of the poliſhed gem is no more than half that of the rough cryſtal out of which it was formed; whence the value of a cut diamond is eſteemed equal to that of a ſimilar rough diamond of twice the weight, excluſive of the coſt of the workmanſhip. The weight, and conſequently the value, of diamonds, is eſtimated in carats; one of which is equal to four grains, and the difference between the price of one diamond and another, *ceteris paribus*, is as the ſquares of their reſpective weights. Thus the value of three diamonds of one, two, and three carats' weight reſpectively, is as one, four, and nine. The average price of rough diamonds, that are worth working, is about 2*l.* ſterling for the firſt carat, and conſequently in wrought diamonds, excluſive of the coſt of workmanſhip, the coſt of the firſt carat is 8*l.* In other words, in order to eſtimate the value of a wrought diamond, aſcertain its weight in carats, and fractions of a carat, multiply this by two, then multiply this laſt product into itſelf, and finally multiply this latter ſum by 2*l.* Hence a wrought diamond of

1	Carat,	is	worth	£ 8
2	-	-	-	32
3	-	-	-	72
4	-	-	-	128
5	-	-	-	200
6	-	-	-	288

7	Carats are worth		£392
8	-	-	- 512
9	-	-	- 612
10	-	-	- 800
20	-	-	3,200
30	-	-	7,200
40	-	-	12,800
50	-	.	20,000
60	-	-	28,800
70	-	-	39,200
80	-	-	51,200
90	-	.	64,800
100	-	.	80,000

This rule, however, actually holds good only in the ſmaller diamonds of 20 carats, and under; the larger ones, in conſequence of the ſcarcity of purchaſers, being diſpoſed of at prices greatly inferior to their eſtimated worth. The value of ſome of the moſt perfect diamonds exceeds that given in the table; but for a ſtone that is flawed, cloudy, or of a bad colour, ſometimes three quarters of the whole tabular value muſt be deducted.

We now proceed to enumerate ſome of the moſt remarkable diamonds, and at the head of the liſt ought unqueſtionably to be placed the great diamond of Portugal, if it were not now become the general opinion, both of jewellers and mineralogiſts, that this ſuppoſed diamond is only a colourleſs topaz. It was found in the diamond mines of Brazil, and is as yet in its native rough ſtate; it weighs 1680 carats.

The largeſt, therefore, of all the undoubted diamonds, is that mentioned by Tavernier, as in the poſſeſſion of the great Mogul; its weight, according to the ſame author, (who himſelf weighed it,) is $279\frac{9}{16}$ carats: its form and ſize are equal to about half a hen's egg. It was found in the mine of Colore, to the eaſt of Golconda, about the year 1550.

The next in ſize is a Braſilian diamond, in poſſeſſion of the king of Portugal, weighing 215 carats, and of ſingular beauty.

An oriental diamond, formerly belonging to one of the Perſian ſultans, and at preſent in poſſeſſion of the emperor of Ruſſia, deſerves the next place: it is without flaws or faults of any kind, and weighs 193 carats. It was purchaſed by the late empreſs Catherine, for about 90,000*l.* ready money, and an annuity of about 4000*l.* more. Its form is that of a flattened ovoid, and it is about the ſize of a pigeon's egg.

The laſt that deſerves a place among the great diamonds of the world, is the Pitt, or regent diamond; which was brought over from India by an Engliſh gentleman of the name of Pitt, and was ſold by him to the regent duke of Orleans, by whom it was placed among the crown jewels of France, and of which it ſtill forms the great glory. It is cut in the form of a brilliant, and is abſolutely faultleſs; it weighs $136\frac{4}{16}$ carats, and was purchaſed for about 100,000*l.*

Diamonds were much more rare, and of courſe dearer, before the diſcovery of the Braſilian mines of this ſubſtance, than they have been ſince. In the year 1730, the Rio Janeiro fleet brought to Europe no leſs than 1146 ounces of diamonds, the produce of Brazil; in conſequence of which, the price of this article immediately fell three-fourths, and to prevent a ſtill further depreciation, the Portugueſe government reſtricted the number of ſlaves allowed to be employed by thoſe to whom leaſes of theſe mines had been granted.

In order to enable the reader to form ſome judgment of the quantity and value of the diamonds poſſeſſed by the ſovereigns of Europe, we ſhall preſent him with an abſtract of a curious inventory of the crown diamonds of France, preſented to the National Aſſembly by a commiſſion of jewellers, appointed for that purpoſe in the year 1791.

	Weight in Carats.	Eſtimated Value in Livres.
1. A brilliant diamond, called *Le Regent* - -	$136\frac{14}{16}$	12,000,000
2. A diamond cut in facets, called *Le Sancy*, perfect in luſtre and tranſparency -	$33\frac{12}{16}$	1,000,000
3. A diamond cut in facets -	$28\frac{6}{16}$	250,000
4. A brilliant diamond -	$26\frac{12}{16}$	150,000
5. A pear-ſhaped diamond, of a peach-bloſſom colour -	$24\frac{13}{16}$	200,000
6. Le Miroir de Portugal -	$21\frac{2}{16}$	250,000
7. A yelloviſh pear-ſhaped diamond - - -	$20\frac{14}{16}$	65,000
8. A roſe-coloured brilliant, flawed	$20\frac{12}{16}$	48,000
9. A colourleſs olive-ſhaped diamond	$18\frac{13}{16}$	85,000
10. A greeniſh brilliant, flawed	$18\frac{11}{16}$	20,000
11. A pale wine-coloured brilliant	$18\frac{9}{16}$	75,000
12. A ſteel-coloured brilliant	$17\frac{7}{16}$	18,000
13. A brilliant, cloudy -	17	50,000
14. Le dizieme Mazarin, cloudy	16	50,000
15. A peach bloſſom-coloured brilliant	$14\frac{14}{16}$	25,000
16. A colourleſs brilliant -	$14\frac{14}{16}$	150,000
17. A peach bloſſom-coloured brilliant	$14\frac{12}{16}$	30,000
18. A brilliant - -	$13\frac{10}{16}$	60,000
19. A browniſh brilliant -	$13\frac{8}{16}$	35,000
20. A yelloviſh brilliant -	$11\frac{10}{16}$	15,000
21. A browniſh brilliant - -	$11\frac{10}{16}$	10,000
22. A yelloviſh brilliant -	$11\frac{6}{16}$	15 000
23. A peach-bloſſom coloured brilliant	$11\frac{2}{16}$	10,000
24. A pale blue brilliant -	$10\frac{7}{16}$	30,000
25. A browniſh brilliant - -	$10\frac{4}{16}$	25,000
26. A colourleſs brilliant -	10	30,000
27. 15 brilliants, weight unknown, eſtimated at - - -		833,000
28. 54 brilliants, weighing from five to leſs than ten carats each		756,000
29. 227 brilliants, weighing from one to leſs than five carats each		332,700
30. 1631 ſmall diamonds, weighing in all - - -	425	77,228
31. 12 diamonds, chiefly roſe diamonds, and flawed -	84	82,700
Royal State Dreſs, *Parure blanche.*		
32. 12 brilliants, weighing from two to 20 carats each, and 163 ſmaller - - -		413,000
33. Plaque de l'ordre du Saint Eſprit, 9 brilliants from 7 to 14 carats each, and 286 ſmaller ones - - -		324,000
34. Epaulette, 12 brilliants from 3 to 19 carats each, -		306,000
35. Croix du cordon, 6 large brilliants, and 143 ſmaller -		200,000
Parure de Couleur.		
36. A rich ſky-blue brilliant -	$67\frac{2}{16}$	3,000,000
37. A pale blue brilliant -	$31\frac{12}{16}$	300,000
38. Croix du cordon, 13 larger brilliants, 362 ſmaller - -		10,000
39. Epaulette, 9 larger brilliants, 197 ſmaller - - -		47,000

	Weight in Carats.	Eſtabliſhed Value in Livres.
40. Epée de diamans, 2189 roſe diamonds - -	400	329,075
41. Diamond buttons, larger brilliants	112	294,851
——— ſmaller do.	440	
42. Sundry other diamonds of various qualities - -		315,000

The principal uſe of diamond is in ornamental jewellery: it is alſo employed by glaziers for cutting glaſs; by lapidaries for cutting and engraving upon the hardeſt gems, and in the finer kinds of clock-work.

The mineralogical ſituation of the diamond is not very well aſcertained. It occurs in India, in detached cryſtals, in a kind of indurated ochery gravel, not far from the ſurface of the ground; but whether or not this is its native bed is unknown. The diamond mines of India extend throughout the whole chain of the Ghauts, from Bengal to cape Comorin: many of theſe, however, are at preſent abandoned, the chief that are now worked being ſituated between Golconda and Maſulipatam. The earth which affords them being dug up and broken to pieces, is carefully waſhed till the water comes off colourleſs; the reſidue is then ſpread thin on mats in the ſun, and the diamonds are diſcovered by their ſuperior brilliancy. This valuable gem is alſo found in Borneo and in Brazil: the diamonds of this latter country are procured in the mountainous diſtrict called Serro do Frio, and are contained in alluvial beds of ferruginous ſand.

Diamonds have been found in the Eaſt Indies, principally in the kingdoms of Golconda, Viſapour, Bengal, and the iſland of Borneo. There are four mines, or rather, two mines and two rivers, whence diamonds have been drawn. The mines are, 1. That of Raolconda, in the province of the Carnatic, 17 gos, of four French leagues each, from Golconda, and about 13 gos from Viſapour. It has been diſcovered about 250 years. (See RAOLCONDA.) 2. That of Gani, or Colore, ſituated on the ſouthern bank of the Kiſtnah, and not far from Condavir. It was diſcovered about 170 years ago by a peaſant; who, digging in the ground, found a natural fragment of twenty-five carats. 3. That of Sumbulpour, a large town in the kingdom of Bengal, near the diamond mine; this is the moſt ancient of them all. It ſhould rather be called that of Goual, which is the name of the river, in the ſand whereof theſe ſtones are found. Laſtly, the fourth mine, or rather the ſecond river, is that of Succudan, in the iſland of Borneo. There are alſo the famous diamond mine of Bundelcund, at Panna, or Purna, 165 geographical miles from Bilſah; another at Beiragur, near the Mahanuddy river, and not far from that of Sumbulpour, which is of more modern date than the other; and another near Gandicotta, on the ſouth bank of the Pennar river.

DIAMOND-*mine of Raolconda*.—In the neighbourhood of this mine the earth is ſandy, and full of rocks and copſe: in theſe rocks are found ſeveral little veins, of half, and ſometimes a whole inch broad, out of which the miners, with a kind of hooked irons, draw the ſand, or earth, wherein the diamonds are; breaking the rocks when the vein terminates, that the track may be found again, and continued. When a ſufficient quantity of earth, or ſand, is drawn forth, they waſh it two or three times, to ſeparate the ſtones therefrom: the miners work quite naked, except for a thin linen cloth before them; and, beſides this precaution, they have likewiſe inſpectors, to prevent their concealing of ſtones: which, however, in ſpite of all their care, they frequently find means to do, by watching opportunities, when they are not obſerved, and ſwallowing them down.

DIAMOND-*mine of Gani*, or *Colore*.—In this mine are found a great number of ſtones, from ten to forty carats, and even more; and it was there that the famous diamond of Aurengzebe, the great mogul, which, before it was cut, weighed 793 carats, was found. The ſtones of this mine are not very clear; their water is uſually tinged with the quality of the ſoil; being black, where that is marſhy; red, where it partakes of red; and ſometimes green and yellow, if the ground happen to be of thoſe colours. Another defect, of ſome conſequence, is a kind of greaſineſs appearing on theſe diamonds, when cut, which takes off part of their luſtre. There are uſually no leſs than ſixty thouſand perſons, men, women, and children, at work in this mine.

When the miners have found a place where they intend to dig, they level another, ſomewhat bigger, in the neighbourhood thereof, and encloſe it with walls about two feet high, only leaving apertures, from ſpace to ſpace, to give paſſage to the water: after a few ſuperſtitious ceremonies, and a kind of feaſt, which the maſter of the mine makes for the workmen, to encourage them, every one goes to his buſineſs, the men digging the earth in the place firſt diſcovered, and the women and children carrying it off into the other, walled round. They dig twelve or fourteen feet deep, and till ſuch time as they find water; then they ceaſe digging: and the water, thus found, ſerves to waſh the earth two or three times; after which, it is let out at an aperture reſerved for that purpoſe. This earth being well waſhed, and well dried, they ſift it in a kind of open ſieve, or riddle, much as we do corn in Europe; then they thraſh it, and ſift it afreſh; and, laſtly, they ſearch it well with the hands, to find the diamonds. They work naked here, as in the mine of Raolconda, and are watched, after the like manner, by inſpectors.

DIAMOND-*mine of Sumbulpour*, or *river Goual*.—Sumbulpour is a large town built all of earth, and covered with branches of cacao-tree: the river Goual runs by the foot thereof, in its paſſing from the high mountains, towards the ſouth to the Ganges, where it loſes its name. It is from this river that are brought all our fine diamond-points, or ſparks, called natural ſparks. They never begin to ſeek for diamonds in this river till after the great rains are over, that is, after the month of December; and they uſually even wait till the water is grown clear, which is not before January: the ſeaſon at hand, eight or ten thouſand perſons, of all ages, and both ſexes, come out of Sumbulpour, and the neighbouring villages. The moſt experienced among them ſearch and examine the ſand of the river; going up it from Sumbulpour to the very mountain whence it ſprings. A great ſign that there are diamonds near, is, the finding of thoſe ſtones which we Europeans call thunder-ſtones. When all the ſand of the river, which at that time is very low, has been well examined, they proceed to take up that wherein they judge diamonds likely to be found; which is done after the following manner: they dam the place round with ſtones, earth, and faſcines: and, lading out the water, dig about two feet deep: the ſand, thus got, is carried into a place walled round on the bank of the river. The reſt is performed after the ſame manner as at Colore, and the workmen are watched with equal ſtrictneſs.

DIAMOND-*mine in the iſland of Borneo*, or *river of Succudan*. We are but little acquainted with this mine; the prince who reigns in that part of the iſland not allowing ſtrangers to have any commerce in theſe ſtones: though there are very fine ones to be bought at Batavia, brought thither by ſtealth. They were anciently imagined to be ſofter than thoſe of the other mines; but experience ſhews, they are in no reſpect inferior to them.

Diamond mines were diſcovered about the year 1728, in the Brazils belonging to the king of Portugal, who, in the year 1740, let them to a company at Rio Janeiro, for a certain ſtipulated annual rent, which is ſaid to be 130,000 cruſades,

on condition that the ſaid company employ no more than 600 ſlaves in working them; ſince which time the value of diamonds is diminiſhed.

The factitious diamonds made in France, called temple diamonds, on account of the temple at Paris, where the beſt of them are made, fall vaſtly ſhort of the genuine ones; accordingly, they are but little valued, though the conſumption thereof is pretty conſiderable for the habits of the actors on the ſtage, &c. See PASTES.

DIAMONDS, *Corniſh*, in *Natural Hiſtory*, a name given in England to all the ſpecies of cryſtals, which are compoſed of a column, terminated at each end by a pyramid. The name takes in two genera of cryſtal, of each of which there are ſeveral ſpecies. Dr. Hill has determined this to be the true figure of perfect cryſtal, and accounts all thoſe which are affixed by one end to ſome ſolid body, and terminated at the other by a pyramid, to be mutilated or imperfect cryſtals. The ſame author, according to the length or thickneſs of the intermediate column, has divided theſe bodies into two genera, the firſt the macroteloſtyla, the other the brachyteloſtyla. See MACROTELOSTYLA and BRACHYTELOSTYLA.

DIAMOND is an inſtrument of conſiderable uſe in the glaſs manufactory, for ſquaring the large plates, or pieces; and among glaziers for cutting their glaſs.

Theſe diamonds are differently fitted up. That uſed for looking-glaſſes, and other large pieces, is ſet in an iron ferril two inches long, and a quarter of an inch in diameter. The reſt of the cavity of the ferril is filled with melted lead, which keeps the diamond firm in its place. The glaziers have a handle of box, or ebony, fitted into the ferril to hold it by. In the former there is a little piece of box croſſing the ferril, in form of a little plane, covered at bottom with a thin copper-plate.

DIAMOND, in *Geography*, a ſmall iſland of the Weſt Indies, near the S.W. coaſt of the iſland of Martinico; half a league S. of cape Diamond.—Alſo, a ſmall iſland in the bay of Bengal, near the S.W. coaſt of Ava. N. lat. 15° 50′. E. long. 94° 30′.

DIAMOND *Point*, a cape on the north coaſt of the iſland of Sumatra, in the ſtrait of Malacca. N. lat 5° 20′. E. long. 97° 52′.

DIAMOND, in *Heraldry*, is uſed to expreſs the black colour in the atchievements of noblemen.

Guillim diſlikes the way of blazoning the coats of peers by precious ſtones, inſtead of metals, or colour. But the Engliſh practice allows it. See COLOUR.

DIAMOND-*cutter*. See LAPIDARY.

DIAMOND-*glaſs*. See GLASS.

DIAMOND-*powder* is of great uſe for grinding hard ſubſtances. And Mr. Boyle obſerves, that though it be much dearer than emery, yet it makes ſo great diſpatch, and the tools employed laſt ſo much longer, as greatly to overbalance the cheapneſs of the emery.

DIAMORUM, of the *Old Diſpenſatories*, is ſyrup of mulberries.

DIAMPER, or UDEAMPER, in *Geography*, a town of India, in the country of Cochin, ſaid to be inhabited by Chriſtians of St. Thomas; 15 miles W. of Cochin. N. lat. 9° 57′. E. long. 76° 21′.

DIAMUNA, in *Ancient Geography*, a name given by Ptolemy to a river of India, which ran into the Ganges.

DIAN BEL, in *Geography*, a town of the iſland of Madagaſcar; about 130 miles E. of Carembole.

DIAN *Dane*, a town of Madagaſcar, on the N. ſide of the river Yonghelahe, under the tropic of Capricorn, N. of cape St. Auguſtine.

DIAN *Katzambe*, a town of Madagaſcar; about 30 miles S. of cape St. Auguſtine.

DIAN *Mahe*, a town of Madagaſcar; 130 miles N. of Carembole.—Alſo, a town of the ſame name, on the ſouth ſide of the river Yonghelahe, near cape St. Auguſtine.

DIAN *Manarghon*, a town of Madagaſcar, on the E. ſide of the river Ronnumina; 130 miles N.E. of cape St. Auguſtine.

DIAN *Manaſſa*, a town of Madagaſcar on the N. bank of the river Yonghelahe; about 100 miles N.E. of cape St. Auguſtine.

DIAN *Maſſo*, a town of Madagaſcar, in the ſouthern diſtrict; about 100 miles N.E. of Carembole.

DIAN *Manauove*, a town of Madagaſcar; about 70 miles N.E. of Carembole.

DIAN *Miſſon*, a town of Madagaſcar; about 80 miles N.E. of Carembole.

DIAN *Raholt*, a town of Madagaſcar; 140 miles N.N.E. of Carembole.

DIAN *Raval*, a town of Madagaſcar; 160 miles N.N.E of Carembole.—Alſo, another town of the ſame name, near the ſource of the river Manhouve; about 80 miles N.N.E. of Carembole.

DIAN *Siandrin*, a town of Madagaſcar, 70 miles E. of Carembole.

DIAN *Simamande*, a town of Madagaſcar, near the W. bank of the river Menerandre; about 68 miles N.W. of Carembole.

DIAN *Soreets*, a town of Madagaſcar; 130 miles N.E. of Carembole.

DIANA, in *Ancient Geography*, *Zainah*, a town of Africa, ſituated in the mountains of Mauritania Sitifenſis, where, among other ruins, is found that of a triumphal arch, ſuſtained by two columns of the Corinthian order.

DIANA, in *Mythology*, the daughter of Jupiter and Latona, and twin ſiſter to Apollo. She is ſaid to have been born firſt, and to have aſſiſted her mother in the delivery of Apollo. The ſuffering of Latona on this occaſion, gave Diana an averſion to marriage, though not to gallantry. She is accuſed of having loved and beſtowed her favours on Endymion, Pan, and Priapus. She was the goddeſs of the woods on earth, Luna in heaven, and Hecate in hell. She was the ſame with Iſis, who is the moſt ancient Diana of all. The Greeks, deriving their theology from the Egyptians, adjuſted it to their own ideas, and attributed to the ſiſter of Apollo what they ſaid of the ſiſter of Oſiris.

The moſt known character of this goddeſs is that of her preſiding over woods, and delighting in hunting. Accordingly the Diana venatrix, or goddeſs of the chace, is frequently repreſented in ancient ſtatues; and deſcribed by the Roman poets, as running, with her veſt ſhortened and girt about her, and yet flying back with the wind: ſhe is tall of ſtature; and her face, though ſo very handſome, is ſomewhat manly: her legs are bare, well-ſhaped, and ſtrong: her feet are ſometimes bare, and ſometimes adorned with a ſort of buſkin: ſhe often has her quiver on her ſhoulder: and ſometimes holds a javelin, but more uſually her bow in her right hand. The ſtatues of Diana were frequent in the woods, where ſhe is repreſented as hunting, bathing, and reſting herſelf after fatigue. Diana has been ſometimes repreſented with three bodies, and hence called the triple, three-headed, and three bodied Diana. Hence the name of *Triformis* given her by the poets (Horace, Virgil, Martial, &c.) and the cuſtom of repreſenting her with three heads, one of which on the right was that of a horſe, one on the left that of a dog, and one in the middle that of a boar. Thus Virgil deſcribes her. (Æn. iv.):

" Ter-

"Tergiminamque Hecatem, tria virginis ora Dianæ."

Pauſanias, however, obſerves (in Corin. c. 30.) that this cuſtom was neither univerſal nor very ancient. Her diſtinguiſhing name, under this triple appearance, is Hecate or Trivia; under which character of the infernal Diana ſhe was invoked in enchantments, and repreſented as a Fury, holding inſtruments of terror in her hands, and graſping cords, ſwords, ſerpents, or flaming torches. When ſhe is repreſented as the intelligencer that preſides over the moon, ſhe appears in a car, drawn by ſtags, or by does, but more commonly by horſes of a perfectly white colour, with a lunar crown or creſcent on her forehead.

Diana's love of chaſtity induced the Greeks to give her virgins for her companions. Although ſhe is ordinarily repreſented with a quiver and dogs, drawn in a chariot by two white ſtags: ſhe is ſometimes figured with wings, as we learn from Pauſanias, having in one hand a lion and in the other a panther, her chariot being drawn either by two heifers, or by two horſes of different colours, but this author owns that he does not underſtand the meaning of theſe ſymbols.

When Diana repreſented the moon, ſhe was called *Lucina;* and alſo when ſhe was invoked by women in child-bed, ſhe bore the ſame appellation, and alſo that of *Juno Pronuba.* She had alſo ſeveral other names; ſuch as that of *Trivia*, from her triform figure, and alſo importing that ſhe was worſhipped in the croſs ways, the ſtreets, and public roads, where her ſtatues were commonly erected. She was alſo called *Orthia*, either from a place, denominated Orthione in Arcadia, where ſhe was worſhipped, or rather from the ſeverity with which ſhe puniſhed thoſe of her companions who did not maintain ſtrict chaſtity, or becauſe the youths of Lacedæmon performed the ceremony of *diamaſtigoſis*, (which ſee) before her ſtatues: The name *Orthion* being given by the Greeks to one that was obdurate and inflexible. The names of *Militta*, *Alilat*, and *Anaitis*, were given to her by the Phœnicians, Arabians, and Cappadocians. The appellation of *Deviana* had its riſe from her being fond of hunting, as thoſe who were addicted to this exerciſe were apt to loſe themſelves, or to deviate. Spon (Miſc. Erud. Ant.) is the firſt who has given a print of a monument, where Diana is named *Clatra.* This goddeſs is there repreſented with Apollo, both charged with ſymbols, Apollo with his lyre, holds in his hand Jupiter's thunder, and has his head encircled with rays, and above, the ſun. In a circle Diana has upon her head the creſcent, a turret, and a pine-apple, like Cybele, a ſerpent wreathed about her arm, as Hygeia the goddeſs of health, the Siſtrum of Iſis, a prow of a ſhip, like Iſis ſurnamed Pelagia. This is evidently Diana, becauſe ſhe repreſents the moon, that is, an Iſis, after the manner of the Greeks. The other names of this goddeſs are moſtly derived from the places where ſhe was worſhipped. Diana is eaſily known in the figures that repreſent her, either by the creſcent upon her head, or by her bow and arrows, or by her hunting habit, or by the dogs that accompany her. The Diana of Epheſus was repreſented with a great number of beaſts, and with other ſymbols that ſignified the earth and Cybele, or rather nature herſelf, whom that goddeſs repreſented. She is ſupported by a couple of deer, and bears on her head a pannier of fruit. Thus the Epheſian Diana is commonly exhibited upon Greek imperial coins. Her buſt is known by the creſcent on her brow, and ſometimes by the bow, or quiver, engraven on one ſide.

Diana had many oracles, in Egypt, in Cilicia, at Epheſus, and many others. She had alſo many temples dedicated to her, of which that at Epheſus was the moſt celebrated, and eſteemed one of the ſeven wonders of the world, on account of its ſtructure, ſize, and furniture. This magnificent edifice, built at the common charge of all the ſtates in Aſia, was ſituated at the foot of a mountain, and at the head of a marſh, which place was choſen, according to Pliny, as being the leaſt ſubject to earthquakes. But it was neceſſary, at a very great expence, to make drains for conveying the water that came down the hill into the moraſs and the Cayſter. Philo Byzantius informs us, that, in this work, ſuch a quantity of ſtone was uſed, as almoſt exhauſted all the quarries in the country; and theſe drains or vaults are what the preſent inhabitants take for a labyrinth. In order to ſecure the foundation of the conduits or ſewers, which were to bear the weight of this immenſe building, they laid beds of charcoal, ſays Pliny, well rammed, and upon them others of wool. Two ancient authors have left us ſome account of the conſtruction of this temple; Vitruvius and Pliny. The firſt tells us that it had eight columns in the fore-front and as many in the back-front; that it had a double range of columns round it; and that it was of the Ionic order; which order, he ſays, was firſt made of eight diameters high. Pliny ſays, (lib. xxxvi. cap. 14.) that 220 years elapſed during its conſtruction; that it was 425 feet in length, and 220 in breadth; that it was adorned with 100 columns, each 60 feet high; that 27 were the gifts of ſo many kings; that 36 were enriched with ſculpture, &c. The original paſſage, with a correction in the punctuation, is as follows: "Univerſo templo longitudo eſt ccccxxv pedum, latitudo ducentorum viginti, columnæ centum, viginti ſeptem a ſingulis regibus factæ, ſexaginta pedum altitudine: ex his triginta ſex cœlatæ, &c." In the paſſage, as it is in the original, there is no comma after *centum*; and accordingly it ſeems to intimate, that in the porticoes of this temple were 127 columns, the gift of ſo many kings. Mr. Wyndham (Archæologia, vol. vi. No. 6.) ſays, that this is totally repugnant to the ſymmetry and proportion obſerved by the ancients in the form of their temples; and farther, that it can hardly be ſuppoſed, that 127 Aſiatic kings ſhould have contributed each a column. He therefore propoſes the above emendation, which removes the difficulty. If we then ſuppoſe theſe columns to have been of eight diameters, the diameter muſt have been ſeven feet ſix inches. The columns, therefore, with their intercolumnar ſpaces, and the ten ſteps by which they aſcended to the level of the portico, will very completely fill up the extent of front mentioned by Pliny; and if we ſuppoſe 17 columns in the flank, it will, in like manner, fill up Pliny's length of the temple; and thus it will be eaſy to account for the 100 columns which that writer has aſſigned to this building. Of theſe columns 27 were very curiouſly carved, and the reſt poliſhed. The architect, employed on this occaſion, was Cteſiphon or Cteſifonte (ſee CTESIFONTE), called by Pliny and Strabo Cherſiphron; and the baſ-reliefs of one of the columns were executed by Scopas, the moſt famous ſculptor of antiquity. The altar was adorned with the maſterly ſculptures of Praxiteles, who had, perhaps, ſelected from the favourite legends of the place the birth of the divine children of Latona, the concealment of Apollo after the ſlaughter of the Cyclops, and the clemency of Bacchus to the vanquiſhed Amazons. Nevertheleſs, this temple, though ſuperior to the cathedral of St. Paul at London, is confeſſedly inferior to the church of St. Peter's at Rome. The length of the Epheſian temple was 425 feet, and that of St. Peter's church 840 Roman palms, each palm being very little ſhort of nine Engliſh inches: and, therefore, the length of the former was about two-thirds of the meaſure of the latter. In other dimenſions, it was ſtill more inferior to that ſublime production of modern architecture. However, ſucceſſive emperors, the Perſian, the Macedonian, and the Roman, have revered its ſanc-

tity,

tity, and enriched its ſplendour. This temple enjoyed the privilege of an aſylum, which at firſt extended to a furlong, was afterwards enlarged by Mithridates to a bow-ſhot, and doubled by Marc Antony, ſo that it took in part of the city; but Tiberius, in order to terminate the many abuſes and diſorders that attended privileges of this kind, revoked them all, and declared, that no man, guilty of any wicked or diſhoneſt action, ſhould eſcape juſtice, though he fled to the altar itſelf.

The prieſts, who officiated in this temple, were held in great eſteem, and truſted with the care of ſacred virgins or prieſteſſes, but not till they were made eunuchs. They were called Eſtiatores and Eſſenæ, had a particular diet, and were not allowed, by their conſtitutions, to go into any private houſe. They were maintained with the profits accruing from the lake Selinuſius, and another that fell into it, which muſt have been very conſiderable, ſince they erected a golden ſtatue to one Artemidorus, who, being ſent to Rome, recovered them after they had been ſeized by the farmers of the public revenues. All the Ionians reſorted yearly to Epheſus with their wives and children, where they ſolemnized the feſtival of Diana with great pomp and magnificence: making, on that occaſion, rich offerings to the goddeſs, and valuable preſents to her prieſts. The Aſiarchæ, mentioned by St. Luke, (Acts, xvi.) were, according to Beza, thoſe prieſts whoſe peculiar province it was to regulate the public ſports that were annually performed at Epheſus, in honour of Diana: they were maintained with the collections made during the ſports; for all Aſia flocked to ſee them. The "great Diana of the Epheſians," as ſhe was ſtyled by her blind adorers, was, according to Pliny, a ſmall ſtatue of ebony, made by one Canitia, though commonly believed to have been ſent down from heaven by Jupiter. This ſtatue was at firſt placed in a nich, which, as we are told, the Amazons cauſed to be made in the trunk of an elm. Such was the firſt riſe of the veneration that was paid to Diana in this place. In proceſs of time, the veneration for the goddeſs daily increaſing among the inhabitants of Aſia, a moſt ſtately and magnificent temple was built near the place where the elm ſtood, and the ſtatue of the goddeſs placed in it. This was the firſt temple, but not quite ſo ſumptuous as that which we have above deſcribed, though reckoned, as well as the ſecond, among the wonders of the world. The ſecond was remaining in Pliny's time, and in Strabo's; and is ſuppoſed to have been deſtroyed in the reign of Conſtantine, purſuant to the edict by which that emperor commanded all the temples of the heathens to be demoliſhed: the former was burnt on the day when Alexander was born, by one Eroſtratus, who owned on the rack, that the only motive which prompted him to deſtroy ſo noble a ſtructure, was the deſire of tranſmitting his name to future ages. The ſtates general of Aſia imagined they ſhould prevent the accompliſhment of his intention, by publiſhing a decree, prohibiting the mention of his name. However, their prohibition only excited a greater curioſity; for ſcarcely one of the hiſtorians of that age has omitted to mention ſo extravagant an act, and to announce the name of the criminal. Alexander the Great offered to rebuild the temple at his own expence, provided that the Epheſians would agree to inſcribe his name on the front; but they rejected this offer in a manner that prevented the reſentment of that vain and ambitious prince, telling him, that "it was not fit one god ſhould build a temple to another." The pillars, and other materials that had been ſaved out of the flames, were ſold, and alſo the jewels of the Epheſian women, who, on this occaſion, willingly parted with them; and the ſum thus raiſed ſerved for the carrying on of the work till other contributions came in, which, in a ſhort time, amounted to an immenſe treaſure. The architect who ſuperintended the conſtruction of this edifice was Dinocrates. This is the temple of which Strabo, Pliny, and other Roman writers have given an account. It ſtood between the city and the port, and was built, or rather finiſhed, as Livy tells us, (lib. i. c. 45,) in the reign of king Servius. This temple, after having riſen with increaſing ſplendour from ſeven repeated misfortunes, was finally burnt by the Goths, in their third naval invaſion, A. D. 260.

It appears, on undoubted evidence, that in England the common people, in ancient times, not only feared Diana as a witch, but that they had on many occaſions paid her reverential honours as a goddeſs. That Diana was worſhipped in Gaul, we learn from Polyænus, (lib. viii. Stratag. c. 39.); and in proof of her having been worſhipped likewiſe in Britain, Mr. Sammes (Antiq. of Britain, p. 135.) takes notice of an image which, in the year 1602, was dug out of the ground in Monmouthſhire, that, both by the form and dreſs, as likewiſe by an inſcription found not far from it, appeared to be the figure of that goddeſs. And Mr. Camden thinks it not improbable, that there was anciently a temple of Diana where St. Paul's cathedral now ſtands, from the great number of ox-heads that were found there in digging up the church-yard in the reign of king Edward I., and were then looked upon as Gentile ſacrifices: and in this opinion he is followed by his learned editor, (Gibſon) by Mr. Sammes, Mr. Howel, and others. Dr. Woodward, particularly (in his Letter to Sir Chriſtopher Wren, § 83.) acquaints us that he had in his collection tuſks of boars, horns of oxen and of ſtags, as alſo the repreſentation of deer, and even of Diana herſelf, upon the ſacrificing veſſels, dug up near St. Paul's church; and likewiſe a ſmall image of that goddeſs, found at no great diſtance. From ancient writers it appears, that not only ſtags, but oxen, and alſo ſwine, were ſacrificed to Diana. An ancient MS. in the Cotton library informs us, that in the time of Melitus, the firſt biſhop of London, Ethelbert, king of Kent, built a church to the honour of St. Paul, on the ſite where before ſtood a temple of Diana: and there were alſo certain ceremonies performed at this church, on the day of St. Paul's converſion, by the multitude, which evidently alluded to the worſhip of Diana, and manors held by the ſervice of offering a doe, or buck and doe, at the high altar of the church, on the above-mentioned day. A ceremony of this kind was continued till the days of queen Elizabeth. Jortin's Life of Eraſmus, vol. ii.

Diana, in *Zoology*. See Simia.

Diana's *Peak Mountain*, in *Geography*, one of the higheſt in the iſland of St. Helena, riſing 2692 feet above the level of the ſea.

Diana's *Tree*. See Arbor.

Dianæ *Fanum*, in *Ancient Geography*, a promontory of Aſia Minor, in Bithynia, at the entrance of the Euxine ſea, according to Ptolemy. Jupiter Urius had a temple on this promontory.—Alſo, a place of Italy, in Campania, 30 ſtadia from Capua.—Alſo, a place of Greece, in Attica.

DIANDRIA, in *Botany*, (from δις, *double*, and ανηρ, a *man*,) the ſecond claſs in the Linnæan artificial ſyſtem, containing plants with two ſtamens only, in the ſame flower with the piſtil. It conſiſts of three orders, of which the firſt, *Monogynia*, is by far the moſt numerous. It ſeparates ſuch of the natural order of labiate flowers as have only two ſtamens, from their allies in the 14th claſs, *Didynamia*, whoſe ſtamens are four, two of them longer than the others; and this is one of the unavoidable defects of all artificial ſyſtems, nor has any ſyſtem hitherto contrived, however natural in its

its pretenſions, eſcaped ſimilar or more inconvenient anomalies in ſome part or other. See DIDYNAMIA, and DIADELPHIA. S.

DIANE, in *Geography*, a lake of conſiderable extent on the eaſtern ſide of the iſland of Corſica, which, through a narrow channel, diſcharges itſelf into the Etrurian or Tuſcan ſea. It is famous for its excellent oyſters, which are taken with pikes in thoſe places where the lake is only ten feet deep. The oyſters that are pierced through are pickled; the others are placed in reſervoirs, and ſold at Baſtia, Leghorn, and the iſland of Elba.

DIANELLA, in *Botany*. See DRACÆNA.

DIANENSIS, in *Ancient Geography*, an epiſcopal ſee of Africa, in Numidia, ſituated in the town of Diana, mentioned by Antonine.

DIANES, a people of Aſia, in Galatia. Steph. Byz.

DIANENTERIUM, a maritime place, 100 ſtadia from Conſtance. According to Ortelius, it was a place in the iſland of Cyprus.

DIANIUM, DENIA, a town in Hiſpania Interior, ſituated on an eminence, ſo that it could be obſerved at a diſtance by navigators. It was one of the three towns on that coaſt, the foundation of which was aſcribed to the Marſeilleſe, who called it *Artemiſium*, from the Greek name of Diana. On a promontory of the ſame name it had a temple of Diana, which was much venerated.—Alſo, an iſland of the Mediterranean, in the vicinity of that of Corſica. It was alſo called *Artemiſia*.—Alſo, a promontory of Spain, in the Mediterranean, oppoſite to the iſles called *Pityuſæ*.

DIANO, in *Geography*, a town of Naples, in the province of Principato Citra, 13 miles N.N.W. of Policaſtro.—Alſo, a town of Genoa, about two miles from the ſea, and three from Oneglia.

DIANTHERA, in *Botany*. See JUSTICIA.

DIANTHON, in *Pharmacy*, an aromatic powder, now diſuſed.

DIANTHUS, in *Botany*, (from Διὸς, διὸς, *Jove*, and ἄνθος, a *flower*, a name given by Linnæus to the Pink and Carnation genus, the *Tunica* and *Caryophyllus* of former authors, in alluſion to the magnificence and fragrance of the flowers.) Linn. Gen. 225. Schreb. 303. Willd. Sp. Pl. v. 2. 671. Sm. Fl. Brit. 460. Juſſ. 302. Gærtn. t. 129. Claſs and order, *Decandria Digynia*. Nat. Ord. *Caryophylleæ*.

Gen. Ch. *Cal.* Perianth cylindrical, tubular, ſtriated, permanent, divided into five teeth at the orifice, and furniſhed at the baſe with two pair of ſcales, ſometimes more, croſſing each other, various in length and breadth. *Cor.* Petals five, regular and equal; claws the length of the calyx, narrow, tapering downwards, inſerted into the receptacle; borders horizontally ſpreading, wedge-ſhaped, abrupt, crenate, often bearded or glandular at the baſe. *Stam.* Filaments 10, awl-ſhaped, about the length of the calyx, but five of them commonly ſhorter than the reſt; in ſome ſpecies all united at their baſe; anthers oval-oblong, compreſſed, incumbent. *Piſt.* Germen oval, ſuperior; ſtyles two, awl-ſhaped, uſually longer than the ſtamens; ſtigmas ſimple, linear, acute, recurved, downy on the upper ſide. *Peric.* Capſule cylindrical, covered with the calyx, of one cell, opening by four teeth. *Seeds* numerous, roundiſh, compreſſed, affixed to a ſquare columella about half as long as the capſule. In ſome ſpecies the ſtamens of one flower and the ſtyles of another are occaſionally diminutive and abortive.

Eſſ. Ch. Calyx cylindrical, of one leaf, with ſcales at the baſe. Petals five, with long claws. Capſule ſuperior, cylindrical, of one cell.

The ſpecies are arranged in four ſections, characterized as follows. 1. Flowers aggregate. 2. Fl. ſolitary, ſeveral on the ſame ſtem. 3. Stem ſingle-flowered, herbaceous. 4. Stem ſhrubby. The number of ſpecies in Willdenow are 32; twelve new ones are deſcribed by Dr. Smith in the Prodromus Floræ Græcæ Sibthorpianæ. An attempt was made by the ſame writer in the ſecond volume of the Tranſactions of the Linn. Soc. to define the ſpecies better than they had previouſly been, and ſome unknown to Linnæus are there for the firſt time deſcribed; but ſeveral ſtill remain obſcure. The genus is chiefly European and African, though one or two ſpecies are found in China and Japan.

In the firſt ſection, the moſt remarkable are: D. *barbatus*. Sweet William. "Flowers aggregate, in ſeparate bundles. Scales of the calyx ovate-awl-ſhaped, as long as the tube. Leaves lanceolate." Curt. Mag. t. 207. Ger. em. 598. Native of Germany and Carniola. A hardy perennial herbaceous plant, frequent in gardens, where it varies with different hues of purple, red and white. In a wild ſtate it is ſaid to be red, either plain, or ſpotted with white. The garden varieties thrive beſt in a rather dry calcareous ſoil, but are apt to rot in moiſture, or much manure. Hence they require to be renewed perpetually by ſeed. They can, however, be encreaſed by cuttings, or, as the floriſts term them, pipings. D. *carthuſianorum*. "Flowers moſtly aggregate. Scales of the calyx ovate, awned, ſhorter than the tube. Leaves linear, with three ribs." Found on banks and about the borders of fields, in Germany, Switzerland, and Italy. The flowers are red, with hairy petals. It requires a dry chalky ſoil, or lime rubbiſh, but can ſcarcely be preſerved long in a garden. D. *Armeria*. Deptford Pink. "Flowers aggregate, bundled. Scales of the calyx lanceolate, hairy, as long as the tube."—Engl. Bot. t. 317. Found in gravelly ground in England and other parts of Europe. The petals are ſomewhat lanceolate, toothed, roſe-coloured, elegantly ſpotted with white. D. *japonicus*. Thunb. Fl. Jap. t. 23. Has much of the habit of the Sweet William, but the leaves are broad and elliptical, the calyx-ſcales fringed, and ſhorter than the tube. This has never been introduced into our gardens, and is known only by Thunberg's figure, and the few dried ſpecimens which he has diſtributed amongſt his friends. D. *prolifer*. Engl. Bot. t. 956. Found in gravelly ſoils in ſome few parts of England, is eaſily kept as a hardy annual in gardens, ſowing itſelf ſpontaneouſly. The ruſhy ſtalks are each crowned by a head of ſmall pink flowers, enveloped with numerous large broad ſcarioſe ſcales. Of this ſpecies D. *diminutus* of Linnæus, referred by him to the next ſection, is moſt aſſuredly only a variety, whoſe flowers are ſolitary from poverty of ſoil.

The ſecond ſection comprehends numerous elegant ſpecies, eſpecially D. *Caryophyllus*. Carnation. "Flowers ſolitary. Calyx-ſcales ſomewhat rhomboid, very ſhort. Petals crenate, beardleſs." Engl. Bot. t. 214. Curt. Mag. t. 39. Of this fine and fragrant flower, the varieties of colour and luxuriance are innumerable. Floriſts diſtinguiſh two principal ſubdiviſions, Carnations and Pinks. The latter are diſtinguiſhed by an eye-like ſpot, and a more humble growth, and are moſt aſſuredly a diſtinct ſpecies, though botaniſts have not ventured to define it, ſubject to almoſt as many varieties as the Carnation. Mr. Hudſon told Dr. Smith that he intended this common or pheaſant's-eye pink by his D *arenarius*, it being ſometimes found, ſeemingly wild, on old buildings. Both kinds are propagated by ſeeds, layers, or cuttings. See below. D. *deltoides*. Maiden Pink. "Flowers ſolitary. Calyx-ſcales ovato-lanceolate, acute, two or four. Leaves bluntiſh, ſomewhat downy. Petals crenate." Engl. Bot. t. 61. A native of graſſy gravelly paſtures and fields, eaſily kept in a dry garden, where it forms perennial tufts. The flowers are red, with a dark circle or eye. D. *glaucus* of Linnæus

Linnæus is a variety with white flowers and a violet-coloured eye. They are inodorous. D. *chinenſis*. China Pink. "Flowers ſolitary. Calyx-ſcales awl-ſhaped, ſpreading, leafy, as long as the tube. Petals crenate. Leaves lanceolate." Curt. Mag. t. 25. Native of China, where it is much cultivated, as well as in our gardens. It is annually raiſed from ſeed, and ſome varieties thence frequently occur. D. *ſuperbus*. Superb Pink. "Flowers ſolitary, panicled. Calyx-ſcales very ſhort, pointed. Petals in many capillary ſegments. Stem erect." Smith Spicil. t. 19. Native of Lapland, Denmark, Germany, France, and Switzerland. It requires chalk or lime rubbiſh to ſucceed in a garden, and ſeldom lives more than two or three years. It is renewed by ſeed. The flowers are elegantly feathered, and in an evening highly fragrant. D. *virgineus*. "Flowers ſolitary, few on each ſtem. Calyx-ſcales very ſhort and obtuſe, only two to each flower. Petals crenate." Jacq. Auſtr. App. t. 15. Linn. Sp. Pl. 590. (D. rupeſtris; Linn. Suppl. 240.) Found on lime-ſtone rocks in Auſtria, France, and Switzerland. Haller miſtook this for D. *caryophyllus*, it being his *Tunica*, n. 896. The flowers are inodorous, and inconſpicuous compared with moſt other ſpecies; leaves very ſlender.

Of the third ſection the chief are, D. *cæſius*. Chedder Pink. "Stems ſingle-flowered. Calyx-ſcales roundiſh, ſhort. Petals crenate, hairy. Leaves rough in the margin." Sm. Fl. Brit. 463. Engl. Bot. t. 62. (D. virgineus β; Linn. Sp. Pl. 590.) Native of lime-ſtone rocks in England and Switzerland. It has hitherto been obſerved only on Chedder rocks, Somerſetſhire, and by Mr. Davall on Roche blânche near Orbe, Switzerland. The leaves are very glaucous. Flowers pale pink, very ſweet-ſcented. Some garden pinks, recently introduced, ſeem to originate from this ſpecies. D. *alpinus*. Dwarf Alpine Pink. "Stems ſingle-flowered. Petals crenate. Outermoſt calyx-ſcales leafy, longer than the tube." Jacq. Auſtr. t. 53. A beautiful native of the Alps of Auſtria, Stiria, Siberia, and Savoy, two or three inches high, with large red ſcentleſs flowers, ſometimes more than one on each ſtem.

In the fourth ſection are, D. *arboreus*. "Stem woody. Flowers in bundles. Calyx-ſcales numerous, very obtuſe and abrupt. Leaves linear, glaucous." Sm. in Prod. Fl. Græc. 289. Linn. Sp. Pl. 590. (Betonica coronaria arborea cretica; Bauh. Hiſt. v. 3. 328.) Native of Crete, on rocks near the ſhore, where the late Dr. Sibthorp gathered it. A ſplendid figure of this moſt magnificent ſpecies is deſtined for his *Flora Græca*, that of Bauhin being the only one at preſent extant. The ſtem forms a denſe buſh, two or three feet high. The leaves are thick, narrow, obtuſe and glaucous. Flowers pale red, remarkable for the numerous imbricated ſcales of the calyx. It ſeems to have been formerly in the French gardens, but is now loſt. D. *fruticoſus*. "Stem woody. Flowers in bundles. Calyx-ſcales elliptical, pointed, numerous. Leaves obovate-lanceolate, obtuſe." Sm. in Prod. Fl. Græc. 289. Linn. Sp. Pl. 591. (Caryophyllus græcus arboreus, leucoii folio peramaro; Tourn. Cor. 23. Voyage, v. 1. 70, with a figure.) Found on rocks in the iſland of Seriphos; alſo in Crete. It has the habit of the laſt, to which Dr. Smith, from the examination of old dried ſpecimens only in Tournefort's herbarium, referred it as a variety; but the drawings and better ſpecimens brought to England by Dr. Sibthorp ſhew it to be probably a diſtinct ſpecies. The leaves are broader, green, not glaucous, and the flowers of a much deeper and finer colour. The calyx-ſcales moreover are fewer and more pointed. D. *juniperinus*. "Stem ſhrubby. Leaves awl-ſhaped. Calyx-ſcales about four, obovate with a ſharp point, ſpreading, half as long as the tube." Sm. Tranſ. of L. Soc. v. 2. 303. Native of Crete. A ſmall but very pretty ſpecies, of which no certain figure exiſts, for as Proſper Alpinus deſcribes his Caryophyllus ſylveſtris arboreus, t. 38, as two cubits high, that ſynonym muſt ſurely belong to D. *arboreus*, our preſent plant, though truly ſhrubby, appearing to be ſcarcely a foot high. The leaves are pungent; flowers the ſize of D. *deltoides*, apparently white. D. *contortus*. Georgian Pink. Stem ſhrubby. Leaves awl-ſhaped. Calyx-ſcales about ſix, elliptic-lanceolate, ſhort. Petals twiſted, deeply cut. (D. orientalis; Don. Caut. 101. Sims in Curt. Mag. t. 1069. Caryophyllus orientalis fruticoſus, tenuiſſimo folio, flore laciniato; Tourn Cor. 23 ? Sims.) Dr. Sims informs us this ſpecies is found about Tiflis, in Ruſſian Georgia, and that he received it from the garden of Mr. Loddiges at Hackney. It perhaps ſcarcely belongs to this ſection of the genus, for many in the ſecond have the baſes of their ſtems not leſs woody. The flowers are red, with a very long ſlender calyx, and are remarkable for their twiſted petals. From this laſt ſtriking peculiarity, we have given the above name, for we could not adopt one from the gardeners, which is equally applicable to twenty ſpecies beſides, highly exceptionable in itſelf, and though tolerated in old eſtabliſhed Linnæan ſpecies, never applied by claſſical writers to new ones, any more than names of countries in general.

DIANTHUS, in *Gardening*, comprehends plants of the herbaceous flowery ornamental kind, of which the ſpecies chiefly cultivated in the garden are: the ſweet William, or bearded pink (D. *barbatus*); clove pink or clove gilliflower (D. *caryophyllus*); the common, or maiden pink (D. *deltoides*); the feathered pink (D. *plumarius*); the gray-leaved, or mountain pink (D. *cæſius*); the China pink (D. *chinenſis*); and the ſuperb pink (D. *ſuperbus*.)

Of the firſt ſort, the principal varieties are: the broad-leaved, or ſweet Williams; the narrow-leaved, or ſweet Johns, with ſingle and double flowers in each. And the chief of the ſub-varieties in the firſt, or broad-leaved kind, are, with broad leaves, and tall deep red flowers, with tall fleſh-coloured flowers, with pure white flowers, with white dotted flowers, with ſtriped leaves and red flowers, large double roſe-coloured, with ſweet ſcented flowers, large double with deep purple burſten flowers, and with double variegated flowers.

But in the ſecond, or narrow-leaved variety, they are with narrow leaves and deep red flowers, with pale red flowers, with pale red and fleſh-coloured flowers, with purpliſh white-eyed flowers, with ſnow white flowers, with white and fleſh-coloured flowers, with white and purple flowers, with white ſpotted flowers, and with red flowers and white borders, or painted-lady ſweet-Williams. And it is obſerved by Martyn, that the broad-leaved ſort, with very double flowers of a deep purple, inclining to blue, burſting the calyx, is not ſo much eſteemed; but that the double roſe ſweet-William, with flowers of a fine deep roſe-colour, and ſmelling ſweet, is much valued, as it does not burſt. The mule, or Fairchild's ſweet-William, which is one of the narrow-leaved double ſorts, ſuppoſed to have been produced from ſeeds of a carnation impregnated by a ſweet-William; the flowers are of a brighter red than in either of the former; their branches not quite ſo large, but the flowers have an agreeable ſmell. The narrow-leaved kind are in general the moſt productive of double flowers.

Of the ſecond ſpecies, there are both ſingle and double varieties, with reddiſh flowers, with variegated red and white flowers, with variegated red, white, and purple flowers, with variegated red, ſcarlet, purple, and white flowers, and with variegated red or purple above, and white underneath.

And the carnations are diſtinguiſhed by modern floriſts,

from the difference of variegation into four claſſes: as flakes having two colours only, and their ſtripes large, going quite through the leaves. Bizarres, with flowers ſtriped or variegated with three or four different colours, in irregular ſpots and ſtripes. Piquettes, having a white ground, ſpotted or pounced with ſcarlet, red, purple, or other colours. Painted ladies, with the petals of a red or purple colour on the upper ſide, and entirely white underneath. And each of theſe claſſes have numerous ſub-varieties, eſpecially the third, which was formerly in moſt eſteem with floriſts; but of late years the flakes have been in greater requeſt. It is uſeleſs, however, to enumerate their ſub-varieties, as they are not by any means permanent.

In the Univerſal Dictionary of Gardening, it is mentioned, that the properties of a good carnation are thus ſtated by floriſts: The item of the flower ſhould be ſtraight, ſtrong, and able to ſupport the weight of the flower without hanging down: the flower at leaſt not leſs than from thirty to forty-five inches high: the petals well formed, long, broad, ſtiff, and pretty eaſy to expand; or, as the floriſts term it, make free flowers, being neither too cloſe, nor too thin; the middle of the flower not advanced too high above the other parts; the colours bright, and equally marked all over the flower: the flower very full of petals, ſo as to render it, when blown, very thick in the middle, with the outſide perfectly round. And Martyn adds, "that the lower or outer circle of petals, commonly called the guard leaves, ſhould be particularly ſubſtantial; ſhould riſe perpendicularly about half an inch above the calyx, and then turn off gracefully in a horizontal direction, ſupporting the interior petals, which ſhould decreaſe gradually in ſize as they approach the centre, and this ſhould be well filled with them. All the petals ſhould be regularly diſpoſed, and lie over each other in ſuch a manner, as that their reſpective and united beauties may meet the eye altogether; they ſhould be nearly flat, or at moſt have a ſmall degree of inflection at the broad end; their edges perfectly entire, without notch, fringe, or indenture. The calyx ſhould be at leaſt an inch in length, ſufficiently ſtrong at top to keep the baſes of the petals in a cloſe and circular body; the colours diſtinct, and the ſtripes regular, narrowing gradually to the claw of the petal, and there ending in a fine point. Almoſt one-half of each petal ſhould be of a clear white, free from ſpots." Theſe properties are, however, chiefly expected in the fine potted varieties, which, on coming into blow, are uſually placed together upon a ſtand or ſtage conſiderably raiſed and covered, in order to produce the fulleſt effect, and by protecting them to continue longer in beauty.

The double varieties, as being more large and beautiful in their colours, ſhould be principally cultivated. Some of them, eſpecially the burſters, are extremely large, as three or four inches in diameter over the crown, or top part.

However, whole blowers and burſters are common to moſt of the varieties, eſpecially the flakes and bizarres; the former are thoſe in which the calyx or outer cup is long, and of equal growth, opening regularly each way only at top, to admit a free and equal expanſion of the petals all round: the flowers in theſe, though ſomewhat ſmaller, are more equally expanded, and require leſs trouble in the management of their bloom than in the burſters. The latter are thoſe in which the cup is large, and, as it were, ſwollen, being liable to burſt on one ſide, and permit the petal to break out and produce irregular flowers, if care be not taken to prevent it by tying, and opening the calyx a little on the oppoſite ſide. The whole blowers are on this account the more convenient for culture, where much time cannot be ſpared in attending to the flowers, eſpecially at the time of their blowing.

Of the third ſpecies, there is a cultivated variety in gardens, with white flowers, with a beautiful purple ring, and leaves rather more glaucous than in the common ſort.

Of the ſixth ſpecies Martyn obſerves, the roots often laſt two years in a dry ſoil; but they are generally raiſed from ſeeds annually. In the nurſery grounds, it is generally known by the name of Indian pink. Dr. J. Edward Smith mentions having had a plant from Mr. Sikes's, which ſeemed to be a mule between this and the firſt ſpecies.

And there are varieties, with red flowers, with purple flowers, with white flowers, with variegated flowers, each ſingle and double, and imperial large-flowered.

Of the ſeventh ſpecies, the varieties principally cultivated in the garden are as below, and which flower in the following order: the damaſk pink, which is the firſt of the double ſorts in flower; it has but a ſhort ſtalk; the flower is not very large, nor ſo double as in many others; the colour is of a pale purple, inclining to red. It is very ſweet in its ſmell. The white ſhock, which is thus denominated from the whiteneſs of its flowers, and the borders of the petals being much jagged and fringed: the flower-ſtalks are eight or ten inches in height. Its ſcent is not ſo agreeable as in ſome other ſorts. The pheaſant's eye, of which there are different varieties, and frequently new ones introduced, ſome of which have very large double flowers; thoſe which burſt their pods are the leaſt eſteemed. They have firm flower ſtems, eight or ten inches high: the flowers large, whitiſh, or bluſh-coloured, with dark purple ſpots in the middle. That ſort of pheaſant's eye, called bat's pink, often flowers again in autumn. The cob pink, the ſtalks of which are much taller than in thoſe of the former ſorts; twelve or fifteen inches high; the flowers very double, and of a bright red colour; it has the moſt agreeable odour of all the ſorts; flowering from the latter end of May to the middle of July. The old-man's-head pink, and the painted lady, flower in July, at the ſame time with the carnation, to which they are more nearly allied than to the pink. The firſt, when in its proper colours, is purple, and white, ſtriped, and ſpotted; but it is frequently of one plain colour, as purple: it continues flowering till the froſt in autumn puts a ſtop to it; and the flower having an agreeable ſcent, renders it valuable. The latter is chiefly admired for the livelineſs of its colour; as it is not ſo ſweet, or of ſo long continuance as the other. The clove pink has a large deep red flower, affording a ſtrong ſcent of the clove. And it is ſuppoſed by Martyn, that it is probable, that the red pinks take their riſe from the carnation, whilſt the pheaſant's-eye pinks derive their origin from the fourth ſort. Some, however, give them all as variations of the third; which is not, he conceives, likely.

There are ſingle and double flowers of each of theſe ſorts

Method of Culture.—Though the culture in theſe flowering ornamental plants is effected without much difficulty, conſiderable attention is neceſſary in the management of ſome of the ſorts, to have them flower in the utmoſt perfection and beauty.

Mode of Culture in the Sweet-William kind.—The ſingle ſorts of theſe plants are readily increaſed by ſowing ſeed which has been carefully collected in a bed of light earth, that has not been much enriched by manure, in the latter end of March, or beginning of the following month, either over the ſurface or in ſlight drills, covering it in well: when the plants have attained a proper growth, as about the latter end of June, they ſhould be removed and ſet out on other ſmall beds, prepared for them, planting them out ſix or eight inches diſtant each way, watering them, and keeping them perfectly free from weeds, till the following autumn, or ſpring, when they muſt be taken up, with good balls of earth about their roots, and ſet out where they are to flower. It is by this method that new varieties are produced. Although

though theſe plants are perennial, they ſhould be raiſed every year from ſeed, to have them blow ſtrong, and in the utmoſt perfection.

Theſe, and the double ſorts, may be continued by ſlips or layers. In the former mode the ſlips ſhould be planted out either in the early autumn or ſpring months, where they are to remain, giving them a little water at the time, when the weather is dry. When the ſlips are taken from the young plants, they ſhould be made quite down to the roots, ſo as to have fibres to them. In this way the plants are often good, and flower well. Cuttings, or pipings, managed in the ſame way, alſo ſucceed well in many caſes.

In the latter method, the more tender branches ſhould be laid down in the ſummer months, water being frequently given, when the weather is hot and dry. After they have taken root perfectly, they ſhould be ſeparated or taken off, and be planted out where they are to remain, or in beds of light earth, to be afterwards removed, a little water being given at the time. A few of the beſt ſhould be potted in the beginning of autumn, in order to be more conveniently removed under ſhelter during the ſeverity of winter.

In their general management, theſe plants ſhould be kept neither too moiſt, nor too dry, as in both ſituations they are liable to ſuſtain much injury by the canker.

The ſeed for the culture of theſe plants ſhould be collected, when perfectly ripened, from the beſt and moſt perfect flowers, which have grown at a diſtance from any bad or inferior plants, and be kept in a dry ſituation, till it may be wanted for uſe.

Mode of Culture in the Gilliflower, or Carnation kind.—Theſe plants may be raiſed with facility in the beds or borders of pleaſure-grounds, or gardens, where the ſoil is moderately light and dry; but in order to have them in the greateſt ſuperiority and perfection, it is the practice of floriſts to employ a compoſt prepared by mixing the ſurface vegetable mould of old paſtures with well rotted ſtable-dung, from old hot-beds, or neat's dung in the ſame ſtate, and ſea-ſand, in the proportion of a third of the former, and a fourth of the latter. Theſe materials ſhould be well blended, and lie for a conſiderable length of time, being frequently turned, before they are made uſe of. This mould may be employed, both for filling the pots with, and for forming the beds; and in preparing it for theſe purpoſes, it ſhould not be ſifted fine, but merely well broken down and reduced by the ſpade.

Theſe flowers may be increaſed, and new ones produced by ſeeds, which ſhould be ſown on beds formed of the above compoſt, or on the common borders of light fine mould, from about the middle of March to the ſame period in the following month, raking it in evenly, to the depth of a quarter of an inch, giving ſlight waterings when neceſſary, to promote their vegetation. The fine ſorts are likewiſe often ſown in pots or boxes, in order that they may be readily placed, ſo as to have only the morning ſun when the ſeaſon is hot and dry.

After the plants are come up, they ſhould be kept clear from weeds, and be watered occaſionally, and about July, when the weather is moiſt, be taken up, and pricked out in nurſery-rows, on beds three feet in width, ſetting them ſix inches diſtant, and watering them well at the time, and afterwards, till they have taken freſh root.

At the beginning of autumn, as about September, they will have attained a large growth, and require to be removed into other beds, or ſituations for flowering, in which they ſhould be ſet out in rows eight or nine inches diſtant each way. Some place them in the quincunx manner, as producing a better effect. In this ſituation they ſhould be protected in ſevere weather during the winter, by the application of mats upon hoops placed over the beds. The culture they require in theſe beds is merely that of keeping them free from weeds, occaſionally ſtirring the earth between them by a hoe, and as their flower-ſtalks advance giving them the ſupport of handſome ſticks. They ſhould remain in theſe ſituations till they flower, after which, the ſingles ſhould be taken out, and made uſe of as there may be occaſion, in order to afford full room for the double ſorts, the fineſt and moſt perfect of which being made ſtage or principal flowers, and the others ſet out in the borders; the whole being increaſed as there may be neceſſity, by layering both the firſt and ſucceeding years.

The layer method is that which is principally employed in increaſing and continuing particular varieties, as being the moſt certain. For this purpoſe, the radical leafy ſhoots, proceeding from the crowns of the plants, when of ſix or eight inches growth, are the moſt proper. Theſe ſhould be laid down into the earth, about the latter end of June, or beginning of the following month. The work is performed by ſtripping off the leaves from the lower part of the ſhoot, cutting off a little of the top, and then fixing upon a ſtrong joint, about the middle, to ſlit it with a ſharp knife, nearly half way through, in a ſlanting manner, ſo as nearly to reach the joint above, forming a ſort of tongue on the under ſide of the ſhoot, removing the bark from the enlarged part or joint, to promote the ſtriking root. The mould about the root of the plant ſhould then be ſtirred, and freſh added, where it is wanting, forming a ſlight drill or opening for the branch to be gently laid down into, in a horizontal manner, with the cut part in the earth, the top being left out, and raiſed a little, to keep the ſlit open, pegging the main part of the branch down, by ſhort hooked ſticks, drawing the earth over the cut part. When this method has been practiſed on all the branches, a good watering ſhould be given, to ſettle the mould about them, and frequently repeated when the ſeaſon is dry, in order that they may ſtrike root more perfectly. When the layers thus formed have ſtricken good roots, which is moſtly the caſe in ſix or eight weeks, they ſhould be taken off with the root fibres as entire as poſſible, and after having the ſticky parts about the bottom and the top leaves trimmed off, be planted out either in pots or beds; in the latter method at ſix or eight inches diſtance, with a dibble, a good watering being immediately given, and repeated every two days for ten days or a fortnight, till the plants become well rooted. They ſhould be removed from theſe beds, with balls of earth about their roots, in the beginning of the autumn, into ſmall pots, to have ſhelter during the winter, and in the early ſpring be placed in large ones for flowering; but when there is room, it is a better practice to plant them at once in the pots, as frequent tranſplanting injures their growth. Some floriſts, however, think it beneficial by checking their too vigorous growth.

The leſs fine ſorts may at the above ſeaſon be planted out in the clumps, borders, or other parts, to be left in the beds for flowering.

And theſe flowers may likewiſe be increaſed by cuttings, or pipings, in the manner directed in raiſing pinks, as given below.

And in the winter management of the plants, the fine potted ſorts ſhould about November be removed under the protection of a deep frame covered with glaſs, and plunged cloſely together in a ſlight bed of old tan, dry ſand, or earth. In this ſituation they ſhould have a free admiſſion of air, when the weather is mild, but be covered in froſt, and care ſhould be taken that there be no ſtagnation of moiſture, by the holes in the bottoms of the pots being obſtructed,

as

as by that means they would be much injured, if not deſtroyed.

The flowers which are in the beds ſhould be covered by mats, or other contrivances, when the weather is ſevere at the ſame ſeaſon, care being taken to remove them when the weather is fine in the day time.

And in the ſpring ſeaſon their culture ſhould be continued, by removing thoſe fine varieties which were planted out in ſmall pots in the preceding autumn into large ones for flowering, and ſuch as have remained in the nurſery-beds into the borders or large pots, nine or ten inches over at top, to afford flowers, in each of which the buſineſs ſhould be done by preſerving balls of earth about their roots, about the begining of March, or the following month. The work is performed by cloſing the holes in the bottoms of the pots with pieces of oyſter ſhells or tiles, then filling them half way up with the earth prepared as above, placing the plants with their balls of earth in them, and filling up the vacancies on the ſides with more freſh mould, cloſing it well up about the bodies of the plants, ſo as they may ſtand nearly as high as the tops of the pots, giving a good watering at the time.

When the plants have been thus potted, they ſhould be placed in a ſheltered ſunny ſituation in the open air, being frequently refreſhed with water in hot dry weather.

It is the practice with ſome floriſts to plant two flowers in a large pot: but it is better, as well as more convenient for layering, only to have one; the plants flowering ſtronger, and making more free and finer ſhoots.

And in the ſummer treatment of the flowers, the care of frequent watering ſhould be continued when the weather is hot and droughty, and the ſurface mould be occaſionally ſtirred to promote the growth, and preſerve neatneſs; and when the flower-ſtalks are a little advanced, handſome painted ſticks ſhould be placed for their ſupport both in the pots, and other ſituations; to which they ſhould be neatly tied as they proceed in their growth. When they approach the period of flowering, thoſe which are curious ſhould be removed to a ſtage conſtructed for the purpoſe, and provided with an awning to protect them from being injured by the ſcorching heat of the ſun in the middle of the day, and the effects of too much wet, by which they are continued much longer in blow and beauty.

In regard to ſtages of this nature, they are formed in different methods, according to the fancy of the perſons who make uſe of them. That deſcribed below is a neat mode of conſtructing ſuch apparatus: a platform is erected at the height of eighteen inches or two feet from the ground, conſtituted of two ranges of planks, in order to contain two rows of pots, ſuſtained by poſts in one or two rows underneath, with an open-work roof five or ſix feet in height, covered by means of painted canvas, or ſome other ſuitable material; the whole being ſupported by upright poſts, according to the taſte of the proprietor or perſon who has the management of it.

And the body of the ſtage ſhould be neatly painted for the purpoſe of effect, as well as the preſervation of the wood of which it is conſtructed.

Inſtead of theſe kinds of ſtages, ſome make uſe of a ſort of caps or umbrellas formed of tin, or other ſimilar materials, ſupported on ſtems or ſticks, one for each plant; but theſe are neither ſo convenient, nor afford ſo good an effect as the former, in diſplaying the beauties of the flowers, while in blow.

But whatever may be the nature of the contrivances which are made uſe of for the protection and diſplay of theſe curious flowers, the tying of the plants to the ſupport-ſticks ſhould be continued as the ſtems advance; and ſome curious floriſts contrive to keep them erect at the tops by the uſe of fine wire or other ſimilar means. And in order to procure the flowers as large and fine as poſſible, they trim off all the ſide-ſhoots from the ſtems, leaving only one or two of the top flower buds to expand. When the flowers begin to open, care ſhould be taken to prevent their burſting and expanding in an irregular manner, eſpecially in the burſters, by making a little opening or two in the indentings at the top, and at equal diſtances in other places, by means of fine ſmall pointed ſciſſars. The regular expanſion of the flowers may likewiſe be much aſſiſted, eſpecially where one ſide is more expanded than the other, and they are in pots, by turning the pots, that the contrary ſides may have the full influence of the ſun and light.

And ſome floriſts likewiſe, to blow the curious ſorts as broad and fine as poſſible, make uſe of a kind of ſpreading ſtiff white paper collar, cut open on one ſide, and placed round the bottoms of the flowers to expand the petals upon to the utmoſt extent; but the practice is not in general adviſable, or much had recourſe to at preſent by thoſe who are curious in flowers.

As theſe ſorts of plants flower leſs perfectly as they increaſe in age, it is proper to provide freſh ſupplies of new varieties of them annually by ſowing ſeed obtained from the beſt ſorts in the ſpring ſeaſon, as directed above, and likewiſe to continue the moſt valuable double varieties by means of layering in the ſummer months every year, or the planting of cuttings or pipings, but the firſt is by much the beſt mode of accompliſhing the buſineſs.

And in order to have good ſeed, ſome plants of the beſt and moſt curious ſorts ſhould be preſerved diſtinct, and ſuffered to flower and ripen their ſeed in a perfect manner, which ſhould then be taken off in the pods when the weather is dry, and, after being hardened a little, rubbed out and put up in a bag to be placed in a dry ſituation till wanted for ſowing.

Mode of Culture in the Pink kind.—All the ſpecies and varieties of theſe plants may be increaſed from ſeeds, and the perennial ſorts likewiſe by layers, ſlips, cuttings, and pipings, being managed as directed below.

Where the beſt ſorts only are grown, great care ſhould be taken in providing the ſeed, that it be always had from the beſt and moſt perfect kinds in a full ſtate of maturity.

It ſhould be ſown in the manner directed for carnations, in the beginning of March or the following month, and the plants be managed in a ſimilar manner, only, as being more hardy in their nature, with leſs tenderneſs, and care.

But the ſixth ſpecies is beſt increaſed by ſowing the ſeed on a very gentle hot-bed the beginning of April, as the vegetation is thereby much forwarded. When the plants appear air ſhould be admitted freely, to prevent their drawing up weak; and when of a little growth they may be pricked out with good roots, if the weather be ſuitable, on a bed of light earth, at about three inches diſtance, proper ſhade and water being given. When they are of conſiderable growth, as about the latter end of May, they ſhould be removed with good balls of earth about their roots, and planted where they are to remain for flowering.

The layers ſhould be laid down in the latter end of July or beginning of the following month, in exactly the ſame manner as has been directed for carnations, giving them the ſame culture in every reſpect, till they flower.

In caſes where there are large plants that ſpread conſiderably in a lateral manner, their ſhoots may be covered in the ſpring to the depth of an inch or two; they will thus often take root, form good plants, and be in a ſtate to be planted out in the beginning of the autumn following.

And the ſlips of the young ſhoots, either made from the ſides of the principal ones, or from the roots, ſo as to have fibres to them, and planted out in February, or the two following months, in beds of good mould to a good depth, readily take root, and become good plants before the end of the ſummer, at which time, or in the following ſpring, they may be removed with good balls of earth about their roots, to the places where they are to flower and grow.

Likewiſe cuttings made from the firm ſhoots of the ſame year at the joints, to the length of three or four inches, when planted pretty deeply in a bed of very fine mould, or in large pots at the diſtance of an inch or two, and well watered at the time, readily grow and become plants after being tranſplanted into ſeparate pots, or the borders where they are to flower.

Alſo pipings made by drawing out or breaking off the top parts of the young ſhoots at the joints and trimming them, by which a ſort of pipe is formed, on being planted and managed in the ſame manner, take root and afford good plants.

And in both theſe laſt methods the rooting of the ſhoots is generally promoted by their being cloſely covered by bell, hand, or other ſorts of glaſſes, and having frequent ſlight waterings given round the ſides of them.

In reſpect to the ſeed of the different beſt ſorts, it ſhould be collected in the pods in Auguſt or the following month, when perfectly ripened, chooſing a dry ſeaſon for the purpoſe, ſpreading them out to harden and become dry on paper, or in ſome other manner, after which it ſhould be rubbed out and kept in ſome dry ſituation till it is wanted.

All the different ſpecies and varieties of theſe plants are highly ornamental, and many of them curious, affording an extremely fragrant ſmell during the ſummer months.

The firſt ſort in all the varieties may be made uſe of in the borders, clumps, and other places, where they produce a fine effect by the variety of their flowers in aſſemblage with others of ſimilar growth and ſize.

A few of the double more curious kinds may alſo be cultivated in pots for adorning the more conſpicuous places about the houſe and walk contiguous to it.

The ſecond ſpecies, and all the different varieties of the carnation kind, are proper ornamental plants for the fronts of clumps, borders, and other principal parts of gardens or ornamented grounds, where they have a very agreeable effect from the beauty and elegance of their flowers, as well as the fragrance which they afford during the ſummer ſeaſon.

But the curious double ſorts are moſtly cultivated in pots for the convenience of protection, and being exhibited on ſtages, or in particular ſituations during the time of their blowing, as well as for the eaſe and facility of removal, when neceſſary, to different ſituations.

Likewiſe the third ſort, and the different varieties of the common pink, are all well adapted for producing ornament in the fore parts of beds, borders, and other compartments of pleaſure grounds and gardens, both from the multiplicity of their flowers and their beauty, as well as fragrant ſmell. Theſe are ſometimes uſed for edgings, but from their ſpreading growth they require frequent cutting, when thus employed.

The fourth and fifth ſorts may likewiſe be employed for the purpoſe of affording a greater variety in theſe different ſituations.

The ſixth ſpecies is extremely ornamental from the fineneſs of the colour of the flowers, and the great length of time during which they continue in bloom.

It is obſerved by Martyn, that the ſeventh ſpecies, from the elegance and delicious fragrance of its flowers, is deſerving of being employed in all curious gardens.

In the buſineſs of planting out the various ſorts, the annual kinds are moſtly diſpoſed in patches of three or four plants in each; but the perennial kinds ſingly, as being more buſhy and ſpreading in their habit of growth.

All the different ſpecies and varieties of theſe flowery plants may be brought to blow much more early by being cultivated in frames or the hot-houſe, where there is convenience for it.

DIANUCON, in *Pharmacy*, a kind of rob made with the juice of green walnuts and ſugar: it is now diſuſed.

DIAPALMA, a plaſter much reſembling the diachylon. See EMPLASTRUM.

DIAPASMA, a common name for all powders ſprinkled on the body, whether as perfumes or otherwiſe.

The word comes from the Greek διαπασσειν, *inſpergere, to ſprinkle.*

DIAPASON, in the *Ancient Muſic*, implied the interval or concord of an octave, ſo called, becauſe it contains all the diverſities of ſound. It is $\frac{1}{2} = 612\ \Sigma + 12\ f + 53\ m$. Inſtrument-makers, by diapaſon, underſtand the ſtate of the meaſures, and the proportions of the ſeveral parts of their inſtruments. See ORGAN.

Guido, in his Chap. de Diapaſon & Tinctor; in his Diffinitorium, or Primitive Muſical Dictionary, gives ſeven definitions of the term *diapaſon*.

1. Diapaſon has three diſtinct ſignifications: as a concord, an interval, and a proportion.

2. Diapaſon ariſes from the mixture of two perfect concords, a 4th and a 5th, or from two diſcords, a falſe 5th and a tritonus.

3. Diapaſon is the conjunction and interval of a perfect 4th and 5th.

4. Diapaſon is expreſſed in numbers by $\frac{1}{2}$ or $\frac{2}{4}$. It has, like other intervals, three qualities: it is perfect, imperfect, and ſuperfluous.

5. Diapaſon perfect, conſiſts of five tones and two ſemitones, of which five are concords, and two diſcords.

6. Diapaſon imperfect, is that which conſiſts of four tones, and three ſemi-tones.

7. Is only a diapaſon in appearance: as from b *mi*, to the b *fa* above. Theſe are what we now term falſe octaves, and the moſt offenſive of all diſcords.

DIAPASON *Stop* in an organ, is the foundation upon which the chorus, or full organ is conſtructed; and by the length of the longeſt pipe in that ſtop, the magnitude of the whole inſtrument is known: as an 8 feet, a 16 feet, a 32 feet, or a 64 feet organ, to which ſeveral organs in Holland and Germany amount. The proper compaſs of a voice, or inſtrument, is called its diapaſon. The word is derived from δια, *through*, and παων, *the whole;* becauſe the octave includes the whole compaſs of the whole ſyſtem.

DIAPASON *diateſſaron*. The Pythagoreans did not admit this interval as a conſonance or concord; for this reaſon, that its ratio 8 : 3 was neither multiple nor ſuper-particular. But Ptolemy contends for its being a good concord, for this reaſon, that the diapaſon added to any concord produces a concord. Ariſtoxenus herein agrees with him. Vide Wallis's Append. ad Ptolem. Harm. p. 155.

DIAPASON, among *Muſical Inſtrument-Makers*, is a kind of rule, or ſcale, whereby they adjuſt the pipes of their organs, and cut the holes of their flutes, hautboys, &c. in due proportion, for performing the tones, ſemi-tones, and concords, juſtly.

A ſquare being divided into eight equal parallelograms; the points wherein a diagonal interſects all theſe parallelograms,

grams, expreſs all the uſual intervals in muſic; and on this principle it is that the diapaſon is founded.

There is a particular kind of diapaſon for trumpets, ſerving as a ſtandard, or meaſure, for the different magnitudes they muſt have to perform the four parts of muſic. There is another for ſackbuts, and ſerpents, ſhewing how far they are to be lengthened, or ſhortened, to riſe or fall from one tone or interval to another.

The bell-founders have likewiſe a diapaſon, or ſcale, ſerving to regulate the ſize, thickneſs, weight, &c. of their bells.

DIAPASON-*diaex*, a kind of compound concord; whereof there are two ſorts: the *greater*, or the interval of a major thirteenth, whoſe ratio is $\frac{3}{10}$ths, or VIII + VI = 1063 Σ + 21 *f* + 92 *m*; and the *leſs*, or the interval of a minor thirteenth, whoſe ratio is $\frac{5}{16}$ths, or VIII + 6th = 1027 Σ + 20 *f* + 89 *m*. See CONCORD.

DIAPASON-*diapente*, a compound conſonance, in a triple ratio of 9 to 3.

The diapaſon-diapente is a ſymphony made when the voice proceeds from the firſt to the twelfth tone. The word is properly a term in the Greek muſic: we ſhould now call it a twelfth. It is the interval of a major twelfth, $\frac{1}{3}$, or VIII + V = 970 Σ + 19 *f* + 84 *m*. (See CONCORD.) Martianus Capella thought this interval to be equal to 9 major tones and a minor ſemi-tone, but which exceed it by 2 ſchiſmas (2 Σ).

DIAPASON-*diateſſaron*, a compound concord.

The diapaſon-diateſſaron is a ſymphony wherein the voice proceeds from the firſt tone to the eleventh. This the moderns would rather call an eleventh. It is the interval of a minor eleventh, $\frac{3}{8}$ths, or VIII + 4th = 866 Σ + 17 *f* + 75 *m*. (See CONCORD) M. Capella ſtates this interval to be equal to 8 major tones and a minor ſemi-tone, but which exceeds it by 2 Σ.

DIAPASON-*ditone*, expreſſes the interval of a major tenth, $\frac{2}{5}$ths, or VIII + III = 809 Σ + 16 *f* + 70 *m*. See CONCORD.

DIAPASON-*ſemi-ditone*, is the interval of a minor tenth, $\frac{5}{12}$ths, or VIII + 3d = 773 Σ + 15 *f* + 67 *m*. See CONCORD.

DIAPEDESIS, διαπηδησις, in *Medicine*, a term employed by Galen and his followers, to denote a fourth mode, by which hæmoptyſis may be produced, (in addition to thoſe mentioned under the term DIABROSIS,) namely, when the contained fluids tranſude, as it were, through the unbroken membranes of the veſſels: and, he ſays, that this may happen when the coats of the veſſels become thinner, and the blood is more diſſolved, ſo as to paſs through the pores of the veſſels, as through a ſieve. Quickſilver, ſays Van Swieten, gives no unapt inſtance of this diapedeſis, when it is ſqueezed through leather to purify it; for it tranſudes in minute drops, the leather remaining entire. But, he juſtly adds, although this may ſeem not altogether impoſſible, yet it is hard to conceive that the red blood, which is the moſt denſe of the human fluids, ſhould ſooner force its way through the pores of the membranes of the veſſels, than paſs from the arteries into the veins. See Galen Meth. Med. lib. v. cap. 2. Van Swieten Comment. § 1199.

DIAPENSIA, in *Botany*, (according to profeſſor Martyn, from διαπηδεω, *to mourn*, or *grieve deeply*, probably from its dreary place of growth. But Ambroſinus derives it from δια and πεντε, as if compoſed of five, and in this ſenſe it certainly was applied by the botaniſts of his time to the *Sanicula*, whoſe leaves are compoſed of five lobes. Linnæus, finding the name, as he tells us, in the Flora Lapponica, unoccupied, adopted it for his new Lapland genus, in alluſion, as it ſhould ſeem, to its five-cleft flower and five ſtamens.) Linn. Gen. 79. Schreb. 104. Willd. Sp. Pl. v. 1. 795. Juſſ. 135. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Preciæ*, Linn. *Convolvulis affine*, Juſſ. *Ericæ*, Saliſb.

Gen. Ch. *Cal.* Perianth of eight leaves; the five innermoſt ranged in a circle; the reſt imbricated upon them; all equal, ovate, obtuſe, erect, permanent. *Cor.* of one petal, ſalver-ſhaped; tube cylindrical, pervious, the length of the calyx; limb in five obtuſe horizontal ſegments. *Stam.* Filaments five, linear, flattened, erect, ſhort, inſerted into the top of the tube, between the ſegments of the limb; anthers ſimple, according to Linnæus, but more juſtly repreſented in the *Paradiſus Londinenſis*, as of two diſtinct, ſeſſile, elliptic lobes. *Piſt.* Germen ſuperior, roundiſh; ſtyle cylindrical, erect, its top on a level with the anthers; ſtigma blunt, with three ſlight notches. *Peric.* Capſule ovate, with three cells and three valves, the partitions contrary to the valves. *Seeds* numerous, roundiſh.

Eſſ. Ch. Corolla ſalver-ſhaped, five-cleft. Calyx of five leaves, encompaſſed by three others. Stamens crowning the tube of the corolla. Capſule of three cells. 1. D. *lapponica*. Leaves tongue-ſhaped, recurved, ſmooth. Anthers without ſpurs. Linn. Fl. Lapp. ed. 2. 57. t. 1. f. 1. Sp. Pl. 202. Oed. Fl. Dan. t. 47. Saliſb. Parad. t. 104. Sims in Curt. Mag. t. 1108. Found by Linnæus very abundantly on the Alps of Lapland. We have it alſo from the coaſt of Labradore. Oeder had it from Norway. It bloſſomed in the garden of the right honourable C. Greville, at Paddington, in February, 1808, for the firſt time we believe in England. The branching ſtems form little denſe tufts, clothed with crowded leaves, which ſpread in every direction, and are tongue-ſhaped, recurved, entire, ſmooth, keeled beneath, channelled above; the lower ones permanent, though faded and almoſt black. Flowers ſolitary, on ſimple terminal ſtalks. Corolla of a brilliant white, with yellow anthers. 2. D. *barbulata*. "Leaves ſomewhat wedge-ſhaped, downy beneath. Anthers ſpurred at the baſe." Saliſb. Parad. (Pyxidanthera barbulata; Michaux Fl. Boreal. Amer. v. 1. 152. t. 17.) A native of the mountains of North Carolina. Dr. Sims and Mr. Saliſbury have both indicated the generic affinity of this plant to the former. We have ſeen no ſpecimens of it. S.

DIAPENTE, in *Muſic*, the name given by the Greeks to the interval which we call the 5th, or 2d concord, in point of perfection. (See FIFTH.) The word is formed of δια, *through*, and πεντε, *five*, as, in forming this interval diatonically, it conſiſts of five degrees.

DIAPENTE is alſo uſed, in *Pharmacy*, for a compound of five ſeveral drugs, or ingredients.

DIAPENTE, among *Farriers*, a drink made for horſes of gentian, round birthworth, barberries, myrrh, and ivory-ſhavings, of each a like quantity, which are to be pounded ſeparately, and finally ſearced: this powder, to the quantity of two or three ſpoonfuls, is mixed with a pint and a half of muſcadine, or ſack, or, for want of either, with ſtrong ale or beer, and given in fevers, the cough, glanders, ſurfeits, inflammations, yellows, &c. It is ſaid to purify the blood from all foulneſſes, as well as to reſtrain the overflowing of the gall, working of the ſpleen, &c.

DIAPER is a name given to a particular ſpecies of cloth, uſed chiefly for table linen. It is known by the French by the name of *toile fourré*, and is ornamented with the moſt extenſive figures of any kind of tweeled cloth, excepting damaſk. The mounting of a loom for working diaper is, in principle, much the ſame as a draw-loom, but the figures being leſs extenſive, the mounting is more ſimple,

and is wrought entirely by the weaver, without the aid of any other perſon. As tweeled cloths, of any number of leaves, are only intervowen at thoſe intervals when one of the leaves is raiſed, the woof above, and the warp below, is kept floating, or fluſhed, until the interſection takes place. Of conſequence, the floating yarn above appears acroſs the fabric, and that below longitudinally. This property of tweeled cloths is applied to form the ornamental figures of all kinds of tweeled goods, merely by reverſing the floating yarn when neceſſary. In the ſimpler patterns, this is effected by a few additional leaves of treddles; but when the range of pattern becomes too great to render this convenient, an apparatus, called a *back harneſs*, is employed, and the cloth woven with this mounting is called diaper. Diapers are generally five-leaf tweels, that is to ſay, every thread of warp floats under four threads of woof, and is raiſed, and, of courſe, interwoven with the fifth. This is done either ſucceſſively, forming diagonals at 45° upon the cloth, or by intervals of two threads, which is called the broken tweel. The latter is generally, if not univerſally, adopted in the manufacture of diaper. The reaſon of preferring the broken to the regular tweel, where ornaments are to be formed, is very obvious. The whole depending upon reverſed fluſhing to give the appearance of the figures, and the regular fluſhing that of the ground, the appearance of oblique or diagonal lines through either would deſtroy much of the effect, and materially injure the beauty of the fabric. The broken tweel, on the contrary, reſtores to the tweeled cloth a great ſimilarity of appearance to plain or alternately interwoven fabrics, and, at the ſame time, preſerves the facility of producing ornaments by reverſing the fluſhing. The ſimpleſt kinds of reverſed tweels will be found in the articles DIMITY and DORNOCK. The diaper mounting is repreſented by *Figs.* 1 and 2. *Plate* VIII. *Miſcellany*.

Fig. 1, is the profile ſection of the mounting of a loom for diaper, viewed from the right ſide. A is the breaſt beam before which the weaver ſits when weaving. After paſſing over this beam, the cloth is wound upon the cloth beam below, and kept faſt by the ratchet-wheel K, which is ſecured by a catch, fixed to one of the ſide rails, or knees of the loom, as in plain weaving. The frame-work is not repreſented in the figure, becauſe it would prevent the view of thoſe parts of the mounting which are peculiar to diaper, and differs in nothing from that of a loom for plain cloth of equal breadth and ſtrength of fabric. B is the yarn beam, and I the rods between which the threads of warp paſs. At L is repreſented the point where the warp is intervoven with the woof to form the cloth. The lay and ſhuttle are not repreſented for the reaſon already given. The parts, in which the diaper mounting differs from that of moſt other looms, are at D and C. The former of theſe repreſents the treddles, in number five, worked by five treddles below at E, the front leaf being raiſed, the back leaf ſunk, and the three intermediate leaves ſtationary. At C is the back harneſs moved, when neceſſary, by the weaver's hand, by pulling one of the cords above through the board M, perforated with holes, in each of which is a notch, to ſecure a knot upon the cord, when pulled down to raiſe the leaf.

In the figure the back leaf is raiſed, and all the others ſtationary. The motion is communicated by means of the cords attached to the leaves of the harneſs, which paſſing over the pullies in the box or caſe H, are made faſt to a piece of wood G, fixed to one ſide of the loom, or to the wall of the ſhop, as moſt convenient. The front treddles at D are connected by cords above to the top levers N, and the motion continued to the treddles by long and ſhort marches, as in other looms mounted for ornamental weaving. As diaper fabrics are always of ſtrong coarſe yarn, the eyes of the harneſs leaves are made of iron or copper, and are called nails; one of theſe is repreſented by *fig.* 2. The eyes of the front leaves are made of a length rather more than the whole depth of the ſhed to be formed. When a diaper loom is mounted, the effect of the harneſs is as follows: Let the tweel, which by reverſing forms the figure, be one of five leaves. In this caſe five threads of warp are drawn through every mail of the harneſs, and one of theſe threads through every leaf of the front-mounting. According to each change of pattern, the number of back harneſs leaves is to be arranged. All thoſe which are raiſed will then form the figure, and thoſe which remain ſtationary, the ground. This is effected by the weaver pulling the cords which paſs through the board G, until the number of leaves required be raiſed. He then preſſes down his treddles in ſucceſſion, until a change is required. As the eyes in front are as long as the depth of the ſhed, thoſe threads which paſs through the mails which are raiſed will be ſunk by the top of the eye, and the threads which are ſunk by the harneſs, will be raiſed by the treddles. But as only one leaf of treddles is raiſed, one ſunk, and three ſtationary, only one thread in every five will be affected by the front mounting, for the long eye of the treddle which riſes will have no effect upon that part of the warp which has been already raiſed by the harneſs, and the leaf which ſinks will have as little upon thoſe which are already down. In the raiſed mails forming the pattern, therefore, four threads will always be above the woof, and one below; in the ſunk mails for the ground, the exact converſe takes place. The two croſſed lines between the harneſs and front treddles will ſhew the effect produced. The pattern is thus produced entirely by the harneſs, and the remaining part of the operation is exactly the ſame as common tweeling.

In mounting diaper looms, the mails of the harneſs muſt be tied ſo low as to allow the warp to touch the race upon which the ſhuttle runs, that its motion may not be interrupted. When the webs are broad, it is alſo found convenient to uſe two ſets of top levers, one ſet being at each ſide of the loom, in order to keep the leaves of treddles level, and to facilitate the weaver's power of treading, which in that, as in all heavy work, requires to be firmly done. The horizontal plan of the diaper mounting will be found in *fig.* 8; and the explanation of that figure in the article DRAUGHT and *Cording*.

DIAPERED, in *Heraldry*. See DIAPRÉ.

DIAPHANOUS, in *Philoſophy*, a thing tranſparent, or that gives paſſage to the rays of light; as water, air, glaſs, talc, fine porcelain, &c. See TRANSPARENCY.

The word is formed of διὰ, *through*, and φαίνω, *I ſhew*.

DIAPHANEITY, in the ſchools, the quality of a tranſparent body; or that which denominates it ſuch. See TRANSPARENCY.

DIAPHANES, in *Ancient Geography*, a river of Aſia, in Cilicia, placed by Pliny on the frontiers of Syria.

DIAPHŒNIX, in *Pharmacy*, an ancient electuary, now obſolete, of which dates were a principal ingredient.

DIAPHONIA, in *Ancient Muſic*, a name given by the ancient Greeks to diſcord, as ſounding twice, and by Guido to diſcant, ſinging in two parts.

In the muſic of the middle ages, during the firſt rude attempts at counter-point, diaphonia was ſynonymous with organum, and implied a part ſuper-added to the canto fermo of the church.

DIAPHONICS, from διὰ, *through*, and φωνὴ, *ſound*, is ſometimes uſed for the ſcience of refracted ſound, as it paſſes through different mediums.

DIAPHORESIS, in *Medicine*, ſynonymous with perſpiration. By ſome it has been confined to the inſenſible perſpiration, or halitus, from the ſkin; but this diſtinction is not generally adopted. See DIAPHORETIC.

DIAPHORETIC MEDICINES, are thoſe which promote a diſcharge by the ſkin, whether it be by inſenſible perſpiration, or by ſweat.

In the common language of writers, the term diaphoretic is applied to thoſe medicines only which promote the inſenſible perſpiration, or the ſlighteſt degrees of ſenſible moiſture on the ſkin; and thoſe which occaſion ſweating, they diſtinguiſh by the term of ſudorific, or ſudoriferous; but as, in the medicines ranged by authors under theſe titles, we can find no difference, but in the degree of force, or what ariſes from the manner of adminiſtration, we may comprehend the whole under the title of diaphoretics.

All the diaphoretic medicines operate either by exciting the force of the circulation, or by exciting the extreme veſſels on the ſurface of the body only; and theſe two operations take place ſometimes ſeparately, and ſometimes together. As the aqueous part of the blood paſſes off by the urine or perſpiration, the quantity of theſe excretions muſt neceſſarily be in proportion to the quantity of water, for the time preſent, in the maſs of blood; and the paſſing of it by the one excretion or the other, will be determined by certain circumſtances of the economy, which we ſhall briefly conſider.

The diſpoſition to perſpiration, both in health and in diſeaſe, depends much upon the condition of the ſkin itſelf, although the activity of the general circulation, as we ſee from the effects of exerciſe, as well as of ſome ſtates of fever, may be conſidered as the prime mover of this excretion. Thus a coarſe and dark ſkin, characteriſtic of the melancholic temperament, is leſs diſpoſed to admit of perſpiration, than the ſoft ſkin of the ſanguine temperament; and a ſtate of moderate health of the conſtitution at large is leſs prone to increaſe the action of the exhalant veſſels, than a ſtate of great fullneſs on the one hand, or of languor and relaxation on the other. As the urine and perſpiration are, as it were, counterbalances to each other, whatever increaſes the diſpoſition to the one diminiſhes that of the other. The ſtate of the ſkin is much connected with that of the ſtomach; ſo that thirſt may be relieved by moiſtening the ſkin, and the ſkin is often ſpeedily relaxed by certain ſubſtances, as warm liquors taken into the ſtomach.

There are two means, therefore, by which perſpiration may be induced, and the action of ſudorific medicines promoted, namely, by application to the ſkin, and ingeſta.

When the ſkin is not in a ſtate unfavourable to perſpiration, the application of heat to the ſurface of the body, without any aſſiſtance from powers internally applied, is ſufficient to produce ſweating; and the application of cold, *i. e.* the abſtraction of the heat, can almoſt certainly prevent the ſame, though conſiderable powers are employed within. Thus ſweating may be obtained by the heat of the air, applied as in what is called the dry bagnio, or by increaſing the heat of the ſurface by previous warm bathing, or by accumulating the warm effluvia of the body itſelf upon its ſurface. This laſt may be done by covering up the body very cloſely with ſuch coverings as may both prevent the eſcape of the warm effluvia ariſing from them, and at the ſame time prevent the acceſs of external cold.

But, farther, to favour the diaphoretic action, a quantity of warm liquid may be taken into the ſtomach, which not only excites the general circulation, but particularly, by conſent of the veſſels on the ſurface of the body with the ſtomach, excites the action of thoſe veſſels which pour out ſweat. The uſe of warm liquids alone, eſpecially in the morning, while in bed, where there is a general diſpoſition to perſpiration, is in ſlight febrile caſes, an ample ſudorific.

Theſe two means of covering up the body cloſely, and taking warm liquids into the ſtomach, are what we call the ſudorific regimen; which will often anſwer alone the purpoſe of exciting diaphoreſis; is often neceſſary to the operation of ſudorific medicines; and will always render their operation more complete and permanent. Cullen Mat. Medica, vol. ii.

But although the application of heat to the ſurface of the ſkin will in general excite perſpiration, it will not, as has lately been aſcertained, invariably produce that effect; but, on the contrary, it will, under a certain condition of the ſkin, rather impede than promote the ſudorific proceſs. The omiſſion of this obſervation, added to the falſe opinions reſpecting the importance of forcing perſpiration, has led to much miſchievous practice in febrile diſeaſes. It is now well underſtood, though not ſatisfactorily accounted for, that in the hot ſtage of continued fevers, as in typhus, ſcarlatina, &c. there is a peculiar conſtriction of the veſſels of the ſkin, marked by extreme dryneſs of its ſurface, and accompanied by great heat, which is increaſed by increaſing that heat, by means of external covering, and the excluſion of cool air. In this condition of the body, *cold* affords the only ready means of removing the febrile conſtriction of the cutaneous veſſels, and cold is, in fact, the only ſudorific under ſuch circumſtances. This principle has been fully proved by Dr. Currie, (ſee his Reports on Cold Water, &c.) and has been obſerved by all who have adopted his practice of cold affuſion, or ſponging, in fevers. The writer of this article has frequently employed the ſhower-bath, and the cold waſhing of the ſkin, in the hot ſtate of typhus, and a free perſpiration was its almoſt invariable conſequence. See COLD.

But although the external application of cold water was not often employed in fevers till within the laſt thirty years, yet the internal uſe of cold water, for the purpoſe of exciting perſpiration, appears to have been among the expedients of the ancients in the cure of fevers. Celſus mentions the practice of giving copious draughts of cold water in ardent fevers, and deſcribes the conſequences to be preciſely ſuch as are produced by the cold affuſion externally, as we have frequently witneſſed: the patient, he ſays, falls into a ſound ſleep, the heat remits, and a free perſpiration breaks out, although he had previouſly ſuffered much from thirſt, heat, and reſtleſſneſs. "Fereque poſt longam ſitim et vigiliam, poſt multam ſatietatem, poſt infractum calorem, plenus ſomnus venit, per quem *ingens ſudor effunditur*, idque præſentiſſimum auxilium eſt." De Medicina, lib. iii. cap. 7. He mentions the ſame practice again in the ninth chapter of the ſame book. Galen and his immediate followers, as well as the phyſicians of the ſixteenth century, ſeem alſo to have made much uſe of cold water, and frequently for the purpoſe of exciting ſweat. See Lommius de Febribus.

A curious controverſy took place in this country early in the laſt century, in conſequence of the publication of a book, entitled, "Febrifugum Magnum, or common Water the beſt Cure for Fevers," by Mr. Hancocke, not a member of the medical profeſſion. He aſſerts, that a pint or a quart of cold water, ſwallowed before going to bed, on the firſt or ſecond day of fever, generally produces a copious ſweat, and cuts the fever ſhort; and he has related ſeveral caſes in which theſe effects took place.

There can be little doubt that cold water, received into the ſtomach in the hot ſtage of fevers, produces its diaphoretic effects in conſequence of the ſympathy which exiſts between that organ and the ſkin: and in the ſame way, moſt probably, the vegetable acids and the neutral ſalts operate on the cutaneous veſſels, as is maintained by Dr. Cullen (Ma-

teria Medica, vol. ii. p. 582.) and all the other ſpecies of diaphoretics, which do not excite ſweating by their ſtimulant power upon the heart and arterial ſyſtem; ſuch as ipecacuanha, antimony, &c. Theſe are the only ſort of diaphoretics that can be employed with advantage or ſafety in fevers, where the primary object is to procure a free diſcharge by the ſkin: in fact, the power of ſudorific medicines in curing fevers is now acknowledged to be very limited. From an obſervation that fevers frequently ſubſided on the appearance of a copious ſweat, and an opinion that ſome noxious cauſe of the fever, a *materies morbi*, was thus evacuated by the pores of the ſkin, the old practitioners laboured hard to produce ſweating, and, by imitating the proceſs of nature, to anticipate her criſis, and aid her efforts in the expulſion of the "peccant humours." But experience has decided that the imitations of art do not produce the ſame reſults as the ſpontaneous operations of the conſtitution: a bliſter does not ſupply the place of an eruption or a boil; a purgative is not equally concluſive in its effects as a ſpontaneous diarrhœa; nor does a ſudorific draught, with the proper regimen, produce the ſame criſis as a natural ſweat: inaſmuch as theſe ſpontaneous diſcharges are rather the effects and firſt ſymptoms of a ſalutary change in the diſeaſe, and not the cauſes. (See CRISIS.) Therefore, when theſe ſpontaneous diſcharges occur, our duty conſiſts only in doing nothing that may tend to interrupt them, unleſs where they are obviouſly detrimental. The profuſe ſweats in hectic fever, for example, and the colliquative, which alternate with them, or that which occurs in the latter ſtages of typhus, are of a dangerous tendency, and, therefore, ſhould be checked when it is poſſible.

The value of the other claſs of diaphoretics, which excite ſweat by accelerating the general circulation, ſuch as contrayerva and ſerpentaria, is to be eſtimated, therefore, upon their other properties, the ſtimulant and cordial, rather than upon their ſudorific powers, in the cure of fevers; and they ought only to be employed in thoſe diſeaſes when debility prevails, in aid of the powers of wine and other ſtimulants. In all febrile diſeaſes connected with local inflammation; as in pneumonia, phrenzy, inflammation of the bowels, liver, or other organs, diaphoretics of this ſtimulant nature muſt be carefully avoided; ſince their miſchievous influence, in accelerating the circulation, would more than counterbalance any advantage which might be received by relaxing the veſſels of the ſkin. Of all the ſtimulant diaphoretics, Dr. Cullen conſiders the guaiacum to be one of the moſt valuable, as it affords a matter which paſſes more entirely to the extreme veſſels, and ſeems to ſtimulate the exhalents more in proportion than it does the heart and great arteries. By this means it is both a more ſafe and more effectual ſudorific than thoſe which ſtimulate the latter almoſt only: but acute rheumatiſm, or rheumatic fever, as it is called, is almoſt the only acute diſeaſe in which it can be recommended; and it is a diſeaſe in which the ſweating is ſpontaneouſly profuſe, and bears ſtimulants better than phlegmonous inflammations.

It may be obſerved, that the combination of opium with ſudorific medicines is valuable in two ways; the opium aids the operation of the ſudorific, on the one hand; and, on the other, the ſudorific, by determining to the ſkin, renders the anodyne effect of the opium more certain and complete, and prevents ſome of its unpleaſant influence on the head: for opium, given when the ſkin is dry, or not accompanied by perſpiration in the courſe of its operation, is very apt to occaſion reſtleſſneſs rather than ſleep, and to produce a ſlight approach to delirium, by its influence on the brain: hence the acknowledged value of the combination which is univerſally known by the name of Dover's powder, as a ſafe and active diaphoretic and anodyne; it conſiſts of opium combined with the diaphoretics, ipecacuanha, and ſulphate of potaſs.

Diaphoretic medicines have been employed in various other diſeaſes of a chronic nature: at one period they were believed to have the power of eradicating the venereal diſeaſe, and the ſtimulant ſort, ſuch as guaiacum, opium, and other vegetable matters. They are allowed to have removed ſome of the primary and ſecondary ſymptoms of lues venerea, and to have alleviated others; and they are deemed capable of removing certain ſequelæ of the diſeaſe, where the farther adminiſtration of mercury would prove injurious: but no ſatisfactory evidence has been adduced, to prove that any, or all of theſe vegetables, given ſingly or combined, are competent to the eradication of lues venerea from the animal body. See John Pearſon's "Obſervations on the Effects of various Articles of the Materia Medica in the Cure of Lues Venerea," p. 234, ſecond edition.

Diabetes has alſo been ſaid to have been cured by the uſe of ſudorific medicines. Two caſes of this diſeaſe are recorded by Dr. M'Cormick of Antrim, in Duncan's Medical Commentaries for 1783, in which the continued uſe of Dover's powder, at bed-time, is believed to have effected a cure: and the adminiſtration of the ſame powder, conjoined with the uſe of another powerful diaphoretic, the warm bath, was ſucceſsfully recommended, in one caſe, by Mr. Werner. See "The London Medical Journal for 1790," p. 221. The natural ſtate of the ſkin in diabetes is that of extreme dryneſs, and diaphoreſis is with difficulty produced: but it is reaſonable to ſuppoſe, that, where a free outlet is obtained by the ſkin, the diſcharge by the kidnies will be diminiſhed. It may be doubted, however, whether this change alone can be conſidered as a cure of diabetes; ſince the conſtitutional or organic diſeaſe, with which it is commonly connected, cannot be removed by ſweating.

DIAPHORETIC *antimony*, or *mineral diaphoretic*, is a preparation of antimony, the proceſs whereof ſee under ANTIMONY.

DIAPHRAGM, in *Anatomy*, (from διαφραττω, *I divide*,) the muſcle which ſeparates the two cavities of the abdomen and thorax, and is the chief agent in inſpiration. It is alſo known among anatomiſts by the names of ſeptum tranſverſum, ſeptum muſculare, and in common language, by that of the midriff.

In anatomical deſcriptions it is often divided into two parts; which however are ſo intimately united, that they form in fact but one muſcle. Theſe diviſions are; the *greater diaphragm*, the true ſeptum, which is a thin, broad, and arched tendino-muſcular expanſion, dividing the cheſt from the abdomen: and the *leſſer diaphragm* (appendices or crura diaphragmatis), which is connected to the back part of the former, and deſcends on the front of the bodies of the lower vertebræ. It is remarkable, as Biſchat has obſerved, for the want of ſymmetry in its two halves. Parts of the body belonging to the animal functions, and placed in the middle line, are generally ſymmetrical; perhaps the deviation from this law in the caſe now under conſideration, may be accounted for, according to the remark of that author, by the circumſtance of its being connected in great meaſure with the organic functions, although it is under the controul of the brain.

Its middle conſiſts of a large broad and thin aponeuroſis, or tendon, ſerving as a common point of attachment to all the muſcular fibres, and named the tendinous centre, or central tendon of the diaphragm. This part is the real diviſion of the two cavities, and is placed in the centre of the ſpace which ſeparates them. Its figure is ſomewhat oval on the lateral aſpects; it is contracted into an obtuſe end towards the

the front, and is marked by a lunated notch poſteriorly. Hence it has an obſcure reſemblance to the leaf of trefoil, and conſiſts of two lateral portions, named alæ, a right and left; and a middle anterior part placed before and between the two latter. The poſterior edge of this tendon is its broadeſt part, and is placed near to the bodies of the vertebræ: it becomes gradually narrower towards the front, and the obtuſe end of this part terminates at a ſhort diſtance behind the enſiform cartilage. It conſiſts of fibres purſuing very various directions, and connected into faſciculi, which decuſſate each other: the greater part perhaps goes from the circumference to the centre. The right ala is generally rather larger than the left. From the whole circumference of this tendinous centre the muſcular fibres depart in a radiated manner; and they may be divided into three parts: the anterior, the poſterior, and two lateral. The front portion conſiſts of a few ſhort fibres, proceeding directly downwards and forwards to be fixed to the poſterior ſurface of the enſiform cartilage. They are often divided into a right and left part, and at the interval between theſe the cellular ſubſtance of the anterior mediaſtinum communicates with that of the abdominal cavity. Sometimes this part is wanting altogether.

The lateral fibres are the moſt numerous; they proceed from each ſide of the tendon, diverge, and deſcribe in their courſe ſemicircles with the convexity upwards. They terminate every where at the circumference of the baſis of the cheſt. The moſt poſterior ones are ſhort, and connected with the back diviſion, or crura of the diaphragm: theſe are inſerted in an aponeuroſis, extended from the end of the laſt rib to the tranſverſe proceſs of the firſt lumbar vertebra, and ſometimes called ligamentum arcuatum, although it ſeems to be merely the upper edge of the aponeuroſis of the tranſverſalis. The reſt of the lateral fibres which increaſe conſiderably in length, are inſerted by broad, diſtinct, and flat, tendinous and fleſhy portions on the inner ſurface of the cartilages of the ſix laſt ribs, and in ſome inſtances of the bone of the ribs. Theſe attachments meet with ſimilar ones of the tranſverſalis, and there is ſometimes a continuity of fibre between the two muſcles.

The poſterior fibres (leſſer diaphragm), ariſing from the broad back edge of the tendon, conſtitute a pretty large muſcular maſs, lying over the bodies of the vertebræ; and formed into two faſciculi, named the crura; of which the right is longeſt, and lies moſt on the front; the left is ſhorter, and placed more to the ſide of the vertebral column. At the part where they ariſe from the central aponeuroſis they ſeparate, and leave an oval opening, through which the œſophagus and nerves of the eighth pair paſs from the cheſt into the abdomen; this is the cardiac, œſophageal, or ſuperior orifice of the diaphragm. The two crura now deſcend nearly in a vertical direction, and a faſciculus of fibres is detached from each: theſe faſciculi croſs each other, and complete by their decuſſation the lower part of the œſophageal orifice, and then join the oppoſite crura. The anterior, which deſcends from the left crus to the right, is the moſt conſiderable. The two crura, ſtill deſcending, ſeparate again, and leave a parabolic opening, directly in front of the vertebral column, giving paſſage to the aorta and thoracic duct, and called the aortic or inferior orifice. They then contract into a flattened tendon, which is inſerted in the front and ſides of the bodies of the lumbar vertebræ; *viz.* into the two upper ones on the left, and three on the right ſide, and ſometimes into the tranſverſe proceſs of the ſecond. The tendons of the two crura are united in the middle by an aponeurotic arch, which forms the anterior portion of the aortic orifice, and which ſtretches immediately over that veſſel: they are alſo confuſed with the longitudinal ligament that extends along the bodies of the vertebræ, ſo that their extent cannot always be very eaſily defined. They are more manifeſt on the poſterior than on the anterior ſurface of the crura.

Parts, which paſs through the Diaphragm.

The aorta, thoracic duct, œſophagus, and nerves of the eighth pair come through the openings already mentioned in the crura of the diaphragm. The two apertures which tranſmit theſe parts, are rather placed towards the left ſide of the body, in conſequence of the left crus being placed on the left of the vertebral column. The interval between the two crura is divided into the two orifices by means of the decuſſating faſciculi of fibres: and conſequently the aorta and œſophagus are ſeparated from each other by theſe faſciculi. The œſophageal opening is compoſed entirely of muſcular fibres, and therefore liable to change in its dimenſions: the aortic orifice, on the contrary, is never affected, in its diameter: the lower part being formed by the ſurface of the vertebræ; the ſides by the tendons of the crura cloſely fixed to thoſe bones; and the upper part by the aponeurotic arch joining the two crura. The inferior vena cava goes through a large opening ſituated on the right ſide of the central tendon, and poſſeſſing a nearly circular outline. It is compoſed of three lunated faſciculi of fibres; an anterior, a poſterior, and a left, which decuſſate each other, and thereby give ſomething of a triangular figure to the opening. It is placed near the poſterior edge of the tendon. It is ſometimes made by four faſciculi. The ſplanchnic nerves, and the trunks of the great ſympathetics, go through the crura of the diaphragm ſeparately on each ſide; and are generally accompanied by the origin of the vena azygos.

The inferior or abdominal ſurface of this muſcle forms a greater or leſs concavity; always greater on the right ſide; and leſs marked in the middle than at the ſides. It is covered almoſt univerſally by the peritoneum, which adheres to it pretty cloſely by ſhort cellular threads. Towards the back part on the right ſide it adheres to the ſurface of the liver. It is in contact with the liver, ſtomach, and ſpleen; and at the lower back part with the renal capſules and kidnies without the intervention of peritoneum. Its ſuperior thoracic ſurface is regularly convex, but higher on the right than on the left ſide: the aſſigned reaſon for this difference is the ſituation of the liver. The greateſt convexity of the right ſide is oppoſite to the fourth true rib, while on the left it is not higher than the fifth. The pericardium is ſtrongly attached to the tendinous centre; which on the front and back part correſponds to the two mediaſtina. The ſides of the diaphragm are every where cloſely covered by the pleura, and are in contact with the baſe of the lungs. Some part of the circumference of the muſcle correſponds to the inner ſurface of the falſe ribs, and the intercoſtal muſcles: and hence a wound of this part might paſs through the cheſt and penetrate the abdomen without wounding any part contained in the former cavity. The convexity of the diaphragm deſcribes an elliptical figure; terminating below by a lunated edge in front, and behind rendered irregular by the deſcending crura. The dextro-ſiniſtral diameter is greater than any antero-poſterior meaſurement. The angle which its ſurface forms with the ſpine, is much more acute than that with the ſternum.

The pleura and peritoneum nearly touch, or are ſeparated however, only by cellular texture, in ſome ſituations of the diaphragm; as at the paſſage of the vena cava, and at the interval of the anterior fibres.

Action of the Diaphragm.

When this muſcle contracts, the convexity of its fibres is deſtroyed; inſtead of curved, they now deſcribe ſtraight lines; and the ſpace which is thus gained in the cheſt, is loſt in the abdomen. The contraction of the crura draws down the back part of the tendinous centre, which can deſcend but little in front, and, when it has thus deſcended, is fixed by the anterior fibres. The aponeuroſis conſequently deſcribes a very oblique plane, extended from the enſiform cartilage downwards and backwards. This motion drives the abdominal viſcera, and particularly the liver, ſtomach, and ſpleen downwards, but principally forwards: thus the ordinary action of the diaphragm is felt but little at the lower part of the abdomen, while the anterior parietes of the cavity are puſhed forwards by the impulſe communicated to the viſcera. If the abdominal muſcles, inſtead of yielding, contract upon the viſcera, the effects of the diaphragm's action are particularly felt about the pelvis, as in expelling the urine, fœces, and child in the act of parturition. The cheſt is enlarged by the diaphragm in the perpendicular direction, and alſo laterally at its lower part. When it acts gently, the middle tendon, connected with the pericardium, does not deſcend much; yet it does deſcend, as any perſon may eaſily aſcertain by feeling the pulſation of the heart, and then drawing in his breath, when the beating manifeſtly changes its ſituation, by becoming lower. In more forcible contractions, this part deſcends further, and Haller ſpeaks of its becoming even convex towards the abdomen, in experiments on animals. After exerting its full effect in rendering its fibres ſtraight, or if it could not depreſs the central tendon, it would draw the enſiform cartilage and the lower ribs inwards.

Its action has no effect upon the aorta, as the ſides of the opening, through which that veſſel paſſes, are unyielding, and incapable, by their very ſtructure, of change in diameter. Neither is the return of the blood to the heart through the inferior vena cava affected, as this opening is tendinous, and the fibres draw from all ſides. But the œſophageal opening is very effectually conſtringed, ſince its ſides are entirely muſcular and moveable; we have the power, by means of the will, of cloſing the cardia ſo as to prevent unpleaſant eructations. When the muſcle has relaxed, the abdominal muſcles, by their action, replace the viſcera, and reſtore the diaphragm to its former convexity.

The action of the diaphragm is much affected by the ſtate of mind: hence ariſe laughing, crying, ſighing, &c., which are ſo many modes of reſpiration produced by different mental affections. This connexion appeared ſo ſtrong to the ancients, that they diſtinguiſhed the diaphragm by the ſame word that ſignifies mind, *viz.* φρην; and the adjective *phrenic* derived from that ſource is ſtill applied to parts which belong to the diaphragm. It is alſo conſiderably influenced by the ſtomach; and hence ariſe the phenomena of hiccoughing.

For further remarks on this ſubject, ſee RESPIRATION. For views of the diaphragm, conſult Albinus, Haller "Nova Icon Septi Tranſverſi." Gotting. 1741.; and the "Tabulæ Poſthumæ" of Santorini, tab. x. See alſo the deſcriptions of the ſame authors, and thoſe of Soemmerring and Bichat in their ſyſtems of anatomy.

DIAPHRAGM is uſed for the ſeptum ſcroti. See SCROTUM.

DIAPHRAGM is alſo a general name, given to all partitions, or ſeparations between two parts of a thing; as the little perforated partitions in the tubes of long teleſcopes.

DIAPHRAGMATIC, an epithet applied to parts belonging to the diaphragm: thus, there are the diaphragmatic arteries, nerves, &c. It has the ſame meaning as the term phrenic.

DIAPHRAGMITIS, in *Medicine*, the noſological term for an inflammation of the diaphragm, or rather of that part of the pleura, or lining membrane of the cheſt, which is ſpread upon the diaphragm.

The membranous and muſcular curtain which ſeparates the lower viſcera from thoſe of the breaſt, being called by the ancients *diaphragma* and *phrenes*, the inflammation of it has received various denominations. Hippocrates, Ægineta, &c. mention the diſeaſe under the term *phrenitis*; intimating at the ſame time that there are other kinds of the diſeaſe, but that the firſt is to be treated like a peripneumony. But to diſtinguiſh this, from the proper phrenſy, alſo called phrenitis, conſiſting of inflammation of the brain, Boerhaave, and others, have called the diſeaſe in queſtion *paraphrenitis*; and Sauvages has given it a place in his Noſology, under the title of *paraphreneſis*. See Van Swieten Comment, ad. § 907. Sauvage Noſol. Method, claſs 3. gen. 12.

This inflammation has generally been deſcribed by writers as a very formidable diſeaſe, and diſtinguiſhed by ſome peculiar ſymptoms of great ſeverity. Thus Boerhaave enumerates its ſymptoms: "A *paraphrenitis* is known by an acute continual fever, with an ardent or inflammatory pain of the affected part of the diaphragm, which, in conſequence of its nervous membranes, can hardly bear it; and this pain is greatly increaſed by inſpiration, coughing, ſneezing, filling the ſtomach, reaching, vomiting, compreſſing or ſtraining of the belly at ſtool, or in diſcharging the urine; the breathing is hereby rendered high up in the breaſt, ſmall, quick, and ſuffocative; performed by the ribs or breaſt only, while the abdomen continues inactive; there is a conſtant delirium; a drawing inwards of the hypochondria; a ſardonic or convulſive laugh; a convulſion, a raving, and a gangrene." Aphoriſm 909.

Now it is acknowledged by all the writers, that this diſeaſe conſiſts of an inflammation of the pleura, extended over the diaphragm: *i. e.* of the ſame membrane which is affected in pleuriſy; and therefore ought only be conſidered as a variety of the latter. In fact, if the muſcular part of the diaphragm is ever affected with acute inflammation, it is at leaſt an extremely rare occurrence, and morbid anatomiſts have not pointed out its exiſtence, as connected with any peculiar ſet of previous ſymptoms. But the pleura is frequently found to have ſuffered inflammation, which has not extended to the muſcular ſubſtance, contiguous to it underneath. In theſe caſes Dr. Cullen maintains, and we believe he is fully ſupported by the experience of others, that the ſymptoms do not differ from thoſe of pleuriſy; he affirms that in his long practice he never witneſſed the occurrence of the ſardonic laugh connected with pleuritic ſymptoms; and that delirium often accompanies other forms of inflammation of the lungs and their membranes, depending, it would ſeem, rather on the high degree of fever, and of the phlogiſtic diatheſis accompanying them, than upon the particular part of the membrane, which is inflamed. The moſt important conſideration, however, is, that it is agreed by thoſe who have given the moſt oppoſite opinions of the peculiarities of the diſeaſe, that it muſt be treated like the various forms of pneumonic inflammation. See Van Swieten, loc. cit. Cullen, Noſol. Method. gen. 11. ſpec. 2. *note*.

DIAPHTHORA, from διαφθειρειν, *to corrupt*, is uſed by Galen and Boerhaave, to denote the corruption of the aliments in the ſtomach, and by Hippocrates for the corruption of the fœtus in the womb, and abortion.

DIAPNOICA,

In the more violent degrees of contuſion, the patients require evacuations, eſpecially cooling purgatives frequently repeated. External preſſure and friction, when the extravaſation is conſiderable, will greatly aid its abſorption, and is therefore beneficial. The more important is the bruiſed part, and the more copious the extravaſation, the more aſſiduouſly muſt all theſe remedies be employed; but in leſs extenſive contuſions, the external applications may be ſufficient.

However, the cold fomentations and ſpirituous aſtringents muſt not be applied without proper ſelection. A decoction of diſcutient herbs in wine, or in a mixture of equal parts of wine and water, eſpecially when aponeurotic and tendinous parts have been much injured, produces often the greateſt benefit; and to this may be added alſo ſal ammoniac, when the pain and tenſion have abated. But if the ſkin be abraded, theſe ſaline applications cannot well be employed.

Sometimes the pain increaſes, in ſpite of theſe applications, to ſuch a degree, that emollient cataplaſms and oleaginous frictions become neceſſary: the following method is particularly recommended in ſuch caſes. Rub well the whole bruiſed part, above and below the contuſion, eſpecially below it, with good oil, and then cover the whole with a mixture of olive oil and ſtrong wine-vinegar, formed into a kind of liniment by agitation. This mixture may beſt be applied upon thick lint, wrapped round the whole part; thus, when the ancle has ſuffered the contuſion, a part of the leg and foot muſt be covered with it. Theſe dreſſings are to be renewed twice or thrice a day, till the ſwelling and pain diſappear. The whole part muſt then be frequently rubbed with camphorated ſpirit of wine. When this has been done for about three or four days, a cloth may be applied, ſpread with a thick ointment compoſed of white of egg mixed with crude alum. This may be repeated about three times, with intervals of 12 hours.

The yellow or blue ſpots that remain after the cure of contuſions, may eaſily be made to diſappear, by applying to them a mixture of bran, ſalt, and vinegar, boiled together till the bran has imbibed the fluids.

When the quantity of extravaſated blood is very large, or when it is ſituated in a part where it cannot eaſily be abſorbed, or when it gives riſe to ſymptoms which demand ſpeedy relief, it muſt be immediately evacuated by an inciſion, and the ſore treated like a wound combined with contuſion. The ſame practice muſt alſo be obſerved, when the internal hæmorrhage by which the extravaſation is produced, proceeds from a large veſſel, continues, and requires to be ſtopped by ſome particular applications; or when, beſides the extravaſation, other leſions of the parts are alſo preſent, as, for example, when the bone has been ſhattered. Should there ſtill remain lumps of coagulated blood behind, after the uſe of the diſcutient remedies, theſe muſt alſo be removed by inciſions, if they threaten to produce further miſchief by their preſſure.

Blows and contuſions of the *joints* deſerve particular attention: for in theſe ſituations, eſpecially in the knee joint, they are always dangerous. The conſequences are violent pain and impeded motion; the pain is generally ſevere at firſt, but ſometimes not. In the firſt caſe the ligaments, and in the ſecond the glands, or interior parts, of the joint have been principally affected. In the latter caſe the conſequences are dropſy, or even ſuppuration of the joint, which frequently proves fatal. When the ligaments or other external parts of the joint have been injured, the part muſt be kept quiet, and treated, according to the peculiar circumſtances of the caſe, with the remedies formerly mentioned, but eſpecially we ſhould have recourſe to leeches: it may afterwards be waſhed with ſpirituous and ſaline applications. When the pain has ceaſed, and there remains behind, as often happens, a ſtiffneſs in the part, the ſoap, liniment, and vapour bath may be employed with advantage. Should arthritic affections be ſuperadded, ſpeedy relief muſt be procured, and the dangerous conſequences obviated by cupping, bliſters, friction with flannel, and the internal uſe of camphorated remedies. When the ligaments have been ſtretched and relaxed by a fall, the German ſurgeons apply, with good effect, ſmall bags filled with the warm powder of plaiſter of Paris, mixed with a fourth part of ſal ammoniac and common ſalt.

When the glands, or internal parts of the joint, have been injured, the ſurgeon ought not to intermit the application of appropriate remedies, till the pain has entirely ceaſed; eſpecially repoſe, blood-letting, and cold fomentations. The leſion of a joint, particularly of the knee, by a fall, blow, &c. eaſily gives riſe to a white ſwelling of the part. In ſuch caſes the ſurgeon cannot employ too great care and attention, as the ſymptoms are ſo numerous and diverſified, that it is in vain to expect a fortunate reſult from a careleſs and inert practice.

Internal contuſions are attended, more or leſs, with diſtreſſing and ſerious ſymptoms. If the head be violently contuſed, there is danger leſt the brain ſhould have ſuffered at the ſame time; or leſt the effuſed blood, lying long upon the cranium, ſhould injure the bone by its preſſure, if it be not ſpeedily abſorbed.

When the thorax has been violently contuſed, the heart, lungs, and large blood-veſſels within the cheſt, are liable to partake of the injury; or a rib may be fractured, and may pierce the lungs, ſo as to occaſion alarming conſequences, if not death itſelf.

A general contuſion of the abdomen, or a blow received upon it, may perhaps hurt the liver, ſtomach, uterus, bowels, &c. or may rupture an important blood-veſſel, and thus cauſe the death of the patient by the internal bleeding, inflammation, or ſuppuration.

The judicious ſurgeon will therefore, in ſuch caſes, conſider what internal parts are likely to have ſuſtained an injury, and will adapt his means to the peculiar circumſtances which ariſe. See CONCUSSION, FRACTURE, and HÆMORRHAGE.

CONTWIG, in *Geography*, a ſmall town of France, in the department of Mont Tonnerre, and chief place of a canton in the diſtrict of Deux Ponts, with 780 inhabitants. The canton itſelf is compoſed of 16 communes, and reckons 4114 inhabitants.

CONTY, a ſmall town of France, on the river Seille, in the department of Somme, 12 miles S.E. of Amiens, which formerly gave the title of prince to the ſecond line of the houſe of Bourbon Condé. It has only 759 inhabitants, but is the chief place of a canton, which, in 27 communes, and upon a territorial extent of 220 kiliometres, reckons 9675 perſons, and forms part of the diſtrict of Amiens; $3\frac{1}{2}$ leagues N.N.E. of it.

CONTZ, a ſmall town of France, in the department of Sarre, and chief place of a canton in the diſtrict of Treves. The number of its inhabitants does not exceed 351, and the whole canton has 31 communes, and a population of 4972 individuals.

CONTZEN, ADAM, in *Biography*, a Jeſuit, and native of the duchy of St. Juliers, has been celebrated for his deep knowledge in the learned languages which he taught in the college of Munich, where he died in the year 1635, after having publiſhed "Commentarii in Evangelia in Epiſt. Pauli ad Rom. et ad Corinth." 2 tom. folio. He wrote likewiſe

particularly to direct its treatment with propriety and ſucceſs, it is obviouſly neceſſary to inveſtigate its riſe, progreſs, duration, or recurrence, its preceding and accompanying ſymptoms, and its aſſigned or probable cauſes, with minuteneſs and accuracy. The diſeaſes which reſemble diarrhœa, in the leading characteriſtic, are dyſentery, and cholera; but they differ eſſentially.

Diarrhœa is to be diſtinguiſhed from dyſentery, by being generally without fever, and by the alvine evacuations conſiſting of the natural fæculent matter, though in a more liquid ſtate; and by the abſence of *teneſmus*, or violent bearing down, which attends dyſentery. There is alſo in the latter diſorder more ſevere griping, than in diarrhœa, but this occaſionally occurs in the diarrhœa, and therefore is not a deciſive diſtinction. There is, however, a mutual alliance between the two diſeaſes, which occaſionally paſs into each other; a diarrhœa, if neglected or improperly treated, ſometimes being converted into dyſentery; and a dyſentery, when its worſt ſymptoms have been ſubdued, ſometimes leaving a diarrhœa behind. Dr. Cullen mentions the contagious nature of the dyſentery, as another diagnoſtic ſymptom, but, in this country, and in ſporadic caſes particularly, the dyſentery is not contagious. See DYSENTERY.

A diarrhœa is to be diſtinguiſhed from cholera chiefly by the difference of their cauſes, which, in cholera, are of one peculiar kind, namely, a profuſe overflow of bile; but in diarrhœa, greatly diverſified. Hence the evacuations in the diarrhœa are very various; in cholera they conſiſt chiefly or ſolely of bilious matter, which is copiouſly diſcharged by ſtool, and alſo thrown upwards by vomiting. See CHOLERA.

The varieties in the colour, ſmell, and appearance of the dejections in diarrhœa, have not only given origin to particular denominations for certain forms of the diſeaſe, but they alſo afford very important inſtruction to the practitioner in his enquiry into their peculiar ſeat and cauſe. Thus, when the ſtools are of the proper ſtercoraceous quality, the diarrhœa, which often ariſes from an overgorging of the ſtomach with too much food, has been termed diarrhœa *crapuloſa*. When the food paſſes off by ſtool in an undigeſted ſtate, it is termed D. *lienteria*; this has been conſidered by moſt writers as a diſtinct diſeaſe, but Dr. Cullen has juſtly deemed it a variety of diarrhœa. The ſame obſervation applies to the D. *cœliaca*, or cœliac paſſion, when the ſtools are of a milky appearance, and are ſuppoſed to conſiſt chiefly of chyle, which paſſed the mouths of the lacteals without being abſorbed. When the ſtools conſiſt of a conſiderable portion of a glairy mucus, the D. *mucoſa* or *pituitoſa* is ſaid to exiſt: the ſecretion of the mucus of the inteſtines is particularly augmented by acrid ſubſtances paſſing through them, ſuch as draſtic cathartics, and alſo by the external application of cold, eſpecially to the feet. When very watery and thin, the D. *colliquativa* is produced; when black, the *melæna*, &c. See DEJECTION.

The eſſential part of this diſeaſe, then, conſiſts in a preternatural increaſe of the periſtaltic motion, and of the ſecretions, in the whole or a great part of the inteſtinal canal; and the prediſpoſing cauſe of the diſeaſe, is a peculiar irritability of the inteſtines, and of the ſecreting veſſels which open upon their internal ſurface.

The ſeveral exciting cauſes of diarrhœa may be referred to two different claſſes. The firſt compriſes diſorders of certain parts of the body, which, either from a ſympathy of the inteſtines with theſe parts, or from their connection with the ſyſtem at large, occaſion an increaſed action of the inteſtines, without the transference of any ſtimulant matter from the primary diſeaſed part to them. Thus, the general ſympathy of the inteſtines is often manifeſted in perſons under the influence of certain paſſions of the mind, as anger, fear, and ſome others, which occaſionally excite a diarrhœa. And among the diſeaſes of other parts of the body, which affect the inteſtines, the irritation of dentition, in infants, may be mentioned as a familiar illuſtration, as it is ſeldom difficult and painful without occaſioning diarrhœa. The ſympathy between the ſkin and the bowels is particularly great in many individuals, ſo that a chill, or the application of cold and moiſture, eſpecially to the feet, will generally excite a diarrhœa: and the ſame ſympathy is ſhewn in others, by the occurrence of diarrhœa from the ſuppreſſion of cutaneous eruptions, or the ſtopping of profuſe or habitual diſcharges from ſores, &c.

The ſecond claſs of occaſional cauſes of the increaſed action of the inteſtines, conſiſts of the ſtimuli which are applied directly to the inteſtines themſelves; and theſe are of various kinds. They may be ſubſtances introduced by the mouth; or poured into the inteſtines by the ſeveral excretories opening into them; or poured from certain preternatural openings made into them in certain diſeaſes.

Of the irritating matters introduced by the mouth, the aliments commonly taken in are the firſt to be mentioned; for, although when properly digeſted, they are reduced to a bland and unſtimulating matter; yet when too great a quantity is taken, ſo as to load the ſtomach, and prevent their due digeſtion, they are ſent in a crude and irritating ſtate to the inteſtines, and, ſtimulating the excretories and the ſurface as they paſs along, they excite a diarrhœa, by which the conſtitution rids itſelf of the irritation. Various ſubſtances are often mixed with the aliment, or taken as food, which are of a ſtimulant nature to the inteſtines, although taken in moderate quantity; ſuch as aceſcent fermenting liquors, vegetable acids, crude and ſour fruits; even the ſaline and ſaccharine parts of the food, if taken in an over-proportion, will excite diarrhœa. There are alſo peculiar idioſyncraſies in ſome individuals, in whom particular articles of food, which are altogether inoffenſive to people in general, excite diarrhœa whenever taken. A ſudden change of the diet, as from animal to vegetable matters, and the contrary, is liable to occaſion diarrhœa; as is alſo a change in the water, or bread, to which we have been accuſtomed.

The other matters introduced by the mouth, which may be the cauſes of diarrhœa, are thoſe which are taken as medicines, poſſeſſing the faculty of ſtimulating the alimentary canal. Thus in the liſt of the Materia Medica, we have a long catalogue of thoſe, named cathartics, or purgatives. Theſe, given in a certain quantity, occaſion a temporary diarrhœa, and given in very large doſes, or even moderately in very irritable habits, they may produce it in exceſs, and continue it longer than the uſual time, producing that ſpecies of diarrhœa, named a *hypercatharſis*.

The matters poured into the cavity of the inteſtines, from the excretories opening into them, and which may occaſion diarrhœa, are either thoſe from the pancreatic and biliary ducts, or thoſe from the excretories in the coats of the inteſtines themſelves. The changes in the pancreatic ſecretion cannot be exactly aſcertained; but it is probable that a morbid and acrid fluid may iſſue from it, even while ſtill entire in its ſtructure, but more eſpecially when it is in a ſuppurated, ſchirrous, or cancerous ſtate, and occaſion diarrhœa. We know well, that the bile is often poured out from the biliary duct, both in greater and leſſer quantity than uſual, and diarrhœa is often the conſequence of both; nor can it be doubted, that the bile is often poured out much changed in its qualities, if the condition of the ſtools can be aſſumed as affording evidence of ſuch change. (See DEJECTION.)

Where

Where the bile is increaſed in quantity, and the ſtools are extremely yellow with bilious matter, the diarrhœa, thus occaſioned, muſt be conſidered as a gentle cholera, differing from this diſeaſe only in the leſſer degree of its ſymptoms; and in hot weather, ſuch a diarrhœa *bilioſa* is not uncommon. But beſide bile, varying in quantity and quality, the biliary duct may pour out *pus*, or other matter, from abſceſſes in the liver, which may be the cauſe of a diarrhœa. Some practical writers take notice of a diarrhœa, in which a thin and bloody liquid is diſcharged; which they ſuppoſe to have proceeded from the liver, and have therefore given the diſeaſe the name of *hepatirrhœa;* but it is at leaſt a very rare occurrence. The black diſcharge by ſtool, termed *melæna*, which conſiſts principally of imperfectly coagulated blood, ſometimes, without doubt, proceeds from the liver; but occaſionally from the ſurface of the inteſtines themſelves, as mentioned in the article laſt referred to.

A ſecond ſet of excretories, from which matter is poured into the cavity of the inteſtines, comprehends thoſe from the coats of the inteſtines themſelves; which are either the exhalant extremities of the arteries, or the excretories from the mucous follicles; both theſe ſources occur in prodigious number over the internal ſurface of the whole inteſtinal canal. It is probable that it is chiefly the effuſion from theſe ſources, which, in moſt inſtances, conſtitutes the liquid matter of the ſtools occurring in diarrhœa. The effuſion from theſe excretories may be increaſed, not only by the increaſed action of the inteſtines from the ſtimuli before mentioned, but alſo from an increaſed afflux of fluid from other parts. Thus when the ſuperficial veſſels are contracted by external cold, a greater quantity of fluids may be determined to the inteſtines. In like manner ſerum or other fluids may be abſorbed from the cavities in which they have been ſtagnant, and be poured into the inteſtines, as frequently happens in particular in dropſies. Cullen, Firſt Lines, § 1483.

A third ſource of matter, poured into the cavity of the inteſtines, and producing diarrhœa, is from thoſe preternatural openings, occaſioned by diſeaſes in the inteſtines or neighbouring parts. Thus the blood veſſels on the internal ſurface of the inteſtines may be opened by eroſion, rupture, or anaſtomoſis, and pour into the cavity their blood, which, either by its quantity, or by its acrimony, whether inherent or acquired by ſtagnation, may give riſe to a diarrhœa, evacuating bloody matter. In this way, the *melæna* or *morbus niger*, before-mentioned, is ſometimes produced. The rupture of abſceſſes, ſeated in the coats of the inteſtines themſelves, or in the contiguous viſcera, which, during the inflammatory ſtate, had formed adheſions to the inteſtines, may likewiſe occaſion a diarrhœa, in which purulent or ſanious matter, mixed with more or leſs blood, will be diſcharged.

Diarrhœa, in one or other of the forms above deſcribed, not only occurs alone, as an idiopathic diſeaſe; but it alſo accompanies from time to time many other diſeaſes, of which it becomes a prominent ſymptom, and in which it ſometimes proves critical and ſalutary, but often ſo much the contrary, as to demand particular attention. In fevers, for example, it is not an uncommon occurrence; and if it appears late in the diſeaſe, when the debility is great, it is often a very unmanageable and dangerous ſymptom. After the meaſles a diarrhœa frequently appears, and is often ſalutary; but in many inſtances it has proved more fatal than the diſeaſe itſelf, as is ſaid to have been the caſe in the fatal epidemic meaſles in the iſland of St. Helena, in the year 1807. Diarrhœa is one of the moſt common diſorders attendant on difficult dentition in children; in fact, almoſt every irritation which excites feverishneſs in young children, is apt to occaſion diarrhœa. It is likewiſe a ſymptom of the preſence of worms in the inteſtines, which animals ought, perhaps, to have been enumerated among the morbid ſtimuli of the inteſtines, before detailed. In the laſt ſtage of pulmonary conſumption, a colliquative diarrhœa, which is liable to alternate with the colliquative ſweats, is an almoſt univerſal occurrence.

Our judgment as to the event of this diſorder, thus various in its nature and cauſes, muſt be deduced from a conſideration of the age, conſtitution, and previous ſtate of health of the patient; from the aſſignable cauſes of the diſeaſe, its duration, its concomitant ſymptoms, and its effects upon the general habit, and likewiſe from the operation of the remedies already employed.

Cure.—In conſequence of this great variety in the nature of the diſeaſe, the method of treatment in diarrhœa muſt be neceſſarily various; in many caſes, it can only be palliative; and where the diſcharge is obviouſly ſalutary, it muſt be encouraged under proper regulations. As it conſiſts eſſentially of a preternatural increaſe of the periſtaltic motion, and of the ſecretory actions of the inteſtines; ſo the leading indications of cure will turn upon one or other of the following circumſtances: whether it appear to ariſe from 1. A morbid irritability of the inteſtines; 2. A preternatural ſtimulus applied to them; or, 3. A combination of theſe two. The *firſt* indication will require the irritability to be allayed; the *ſecond*, that the offending matter be expelled, or its acrimony corrected; and the *third* will demand a mixed plan, conſiſting of the other two, either jointly or alternately, together with an attention to the ſtate of other functions and organs, which may affect that of the *primæ viæ*.

The means adapted to fulfil the *firſt* indication, or to allay the morbid irritability of the inteſtines, will conſiſt in the adminiſtration of opiates; and of aſtringents, ſuch as the Catechu, Hæmatoxylon, or logwood, and Kino; the tonic bitters, ſuch as Colombo, Simarouba, and others of that claſs. "There has been ſome heſitation," ſays Dr. Cullen, "about the employment of aſtringent medicines, in recent caſes, upon the ſuppoſition that they might occaſion the retention of an acrid matter that ſhould be thrown out. I cannot, however, well underſtand, or aſſign the caſes, in which ſuch caution is neceſſary; and I think that the power of aſtringents is ſeldom ſo great as to render their uſe very dangerous. The only difficulty which has occurred to me, with reſpect to their uſe, has been to judge of the circumſtances to which they are eſpecially adapted. It appears to me to be only in thoſe caſes, where the irritability of the inteſtines depends upon a loſs of tone: and this I think may occur either from the debility of the whole ſyſtem, or from cauſes acting on the inteſtines. All violent or long continued ſpaſmodic and convulſive affections of the inteſtinal canal neceſſarily induce a debility; and ſuch cauſes often take place, from violent irritation in colic, dyſentery, cholera, and diarrhœa. The ſame objection," Dr. Cullen adds, "has been made to the uſe of opiates, in recent caſes of diarrhœa, as to that of aſtringents; but on no good grounds: for the effect of opiates, as aſtringent, is never very permanent; and an evacuation, depending upon irritation, though it may be for ſome time ſuſpended by opiates, yet always returns very ſoon. It is only by taking off irritation that opiates are uſeful in diarrhœa; and, therefore, when the diſeaſe depends upon an increaſe of irritability alone, or when, though proceeding from irritation, that irritation is corrected or exhauſted, opiates are the moſt uſeful and certain remedy. And though opiates are not ſuited to correct or remove an irritation applied, they are often of great benefit in ſuſpending the effects of that irritation, whenever theſe are violent: and, upon the whole, it will appear, that opiates may be very frequently, and with great propriety, employed in the cure of diarrhœa."

hœa." First Lines, § 1502-3. In the cases of *lientery*, of the diarrhœa *mucosa*, especially when it has arisen from acrid purgation, constituting a *hypercatharsis*, and in all instances of colliquative diarrhœa, the administration of opiates is obviously requisite, and we apprehend there is no room for diversity of opinion on the subject; and these are the principal modifications of diarrhœa, to which this indication is applicable.

The means adapted to fulfil the *second* indication, of removing a preternatural stimulus from the intestines, consist in the administration of evacuants, or correctors of acrimony. Hence the use of emetics, of purgatives, of glysters, with the one view; and of mucilaginous diluents, alkalies, absorbents, antiseptics, with the other.

As indigestion and crudities present in the stomach, are frequently the cause of diarrhœa, so emetics have often been found serviceable in this complaint. Their utility may also extend, perhaps, beyond the mere evacuation of the stomach, as vomiting may occasion some inversion of the peristaltic motion, which is determined too much downwards in diarrhœa. But purging has been supposed more necessary, to remove the crudities that have passed into the bowels, and it is an almost universal practice among the people at large, to give a purge for the cure of a diarrhœa. But this practice, in the opinion of that able physician, whose name we have so often had occasion to quote, we mean Dr. Cullen, is founded on very mistaken notions respecting the disease, and seems to be for the most part superfluous, and in many cases hurtful. It rests upon the supposition of an acrimony present in the intestines, that ought to be carried out by purging. But from whatever source the acrimony, which can excite a diarrhœa, arises, it may be supposed, he says, sufficient to evacuate itself, so far as that can be done by purging; and as in cholera, so in the same kind of diarrhœa, it will be more proper to assist the evacuation by diluents and demulcents, than to increase the irritation by purgatives.

This opinion is extremely rational, and, when merely opposed to the indiscriminate use of purgatives in diarrhœa, its justness is undeniable. But we believe, that, in avoiding one extreme, the professor has given a sanction to another. In a recent case of idiopathic diarrhœa, such as the *crapulosa*, or that from cold, a gentle purgative is seldom, if ever, in the slightest degree hurtful; it expedites the irritating sordes from the bowels, which, however plausible the supposition of their invariably purging off themselves, we believe are frequently found, in fact, to be imperfectly carried off, and to remain partially behind, keeping up a degree of irritation, which continues the diarrhœa, and even converts it into dysentery. Wherever any material degree of tenesmus is observed, a purgative is generally indicated, and, if the bowels be very irritable, its irritating quality may be diminished by combining a small dose of an opiate with it.

The acrimony, which excites diarrhœa, especially in children, is most commonly of an acid nature, and is generated in the stomach, during the imperfect digestion of the food. Alkaline and absorbent medicines tend to neutralize it, and therefore to remove the irritation of this acrimonious cause of diarrhœa. Antiseptics have been recommended, for the purpose of correcting a putrid acrimony in the intestines, in malignant fevers. The theory is questionable; but those antiseptics which are at the same time powerful cordials and stimulants, such as wine, and alcohol, are useful auxiliaries in removing such a diarrhœa, together with other symptoms of those fevers.

When the *third* indication occurs; when there is, at the same time, a morbid irritability of the intestines, and an unusual stimulus applied to them, the latter must be removed or corrected, where that is practicable, by evacuants or other means, and the irritability moderated. Absorbents, such as preparations of chalk, testaceous powders, lime-water taken with milk, will tend to correct any acid acrimony, that may be formed in the canal; while gentle laxatives may be combined with them, such as rhubarb. These are principally indicated in cases of chronic diarrhœa, in debilitated habits. A determination of the fluids to the skin, by diaphoretics, by warm bathing, by restoring suppressed discharges, or substituting such as may be equivalent, by warm clothing, friction, and the exercise of gestation, will aid in fulfilling this indication; especially in cases where the occurrence of diarrhœa is obviously connected with the application of cold, the suppression of cutaneous excretions, or with a generally debilitated habit. This purpose is also more effectually accomplished, when a course of suitable diet is pursued at the same time; especially the use of milk, rice, the amylaceous parts of vegetables, such as arrow root, tapioca, sago, &c. with animal broths and jellies. Dr. Heberden recommends the combination of spices with the vegetable mucilages, as the nutmeg, cinnamon, &c.; or the combination of cretaceous medicines, with the spices, and opiates. He also advises the use of a spoonful of mutton suet dissolved in four ounces of warm wilk, twice a day, both as medicine and nutriment to a patient under chronic diarrhœa. See Commentarii de Morb. Curatione, p. 128. A similar remedy was recommended by sir John Pringle in the diarrhœa which succeeds to dysentery. Dis. of the Army.

Diarrhœa, in *Ancient Geography*, a port of Africa, in the Cyrenaica. Ptolemy.

DIARTHROSIS, in *Anatomy*, is a general term applied to all those conjunctions of bones, which are capable of motion. The various species of diarthrosis are named according to the figure of the united surfaces; or the degree of motion which they are capable of performing. 1. D. *planiformis;* in which the opposed superficies are nearly plain; *e. g.* in the oblique processes of the vertebræ, in the articulations of the carpus, tarsus, &c. 2. D. *orbicularis;* where a rounded head of one bone is received into a cavity of another. Of this there are two kinds; *enarthrosis*, where the head is large, and the cavity deep; as in the hip joint, which is the only specimen in the human body: *arthrodia*, where the convexity and concavity are not so considerable, as in the shoulder, lower joints, &c. The distinctions arising from the extent of motion performed are; 1. D. *laxa*, which admits of distinct motion, and *stricta*, in which the motion is very obscure. The diarthrosis planiformis is in all cases of the latter description; while the D. orbicularis may belong to either kind. The joints of the atlas and occiput, of the ribs and vertebræ, malleus and incus, &c. are cases of D. orbicularis stricta; *i. e.* the joint is formed by a convex head of bone received into a cavity of the other, and the motion allowed of is small in extent. Those examples of D. laxa, in which the bones admit only of flexion and extension, constitute the species *ginglymus*, or hinge-like joint: as in the elbow, second and third joints of the fingers, &c. In other instances one bone can move in a circular direction on the other; and this is called D. trocho-eides; it is exemplified in all the arthrodia articulations.

DIARY, a term sometimes used for a journal, or day-book, containing an account of every day's proceeding. Thus we say diaries of the weather, &c.

Diary *Fever*, is a fever of one day. See Diaria, and Ephemera.

DIAS, in *Ancient Geography*, a town of Asia Minor, in Lycia. Steph. Byz.

DIASCHISMA, in *Ancient Music*, an interval consisting of half a semitone minor. It is an interval so called by Pythagoras, Overend, &c. its ratio is $\frac{524}{531} : \frac{288}{441}$ and is the comma maximum or comma of Boetius, the ancient comma, and the quint-wolf of earl Stanhope; it is the difference between

the apotome and limma, its common logarithm being .9941148,6097, and in the logs. of Euler .0195500, being that decimal part of an octave: it is equal to 12 ſchiſmas and a minute, or $12\,\Sigma + m$. This interval may alſo be compoſed by the following additions of intervals, *viz.* ſchiſma and a major comma: or two ſchiſmas and a minor comma. The following differences of intervals alſo produce the diaſchiſma, *viz.* two minor commas from a ſemitone minimum; a minor comma from two major commas; a tone major from two apotomes; two limmas from a tone major; a medius reſidual from an hyperoche; three minor commas from two enharmonic dieſes; four enharmonic dieſes from three ſemitones minimum; a ſemitone minimum from four major commas; an octave from ſix tones major; ſeven octaves from 12 major fifths; five octaves from 12 minor fourths; and 5 major fifths from ſeven minor fourths. The three laſt give us practicable methods of tuning a diaſchiſma upon an organ, &c., which interval is the *leaſt ſum* that the temperaments of all the minor fourths, and all the temperaments of the major fifths, can amount to, in any douzeave or ſyſtem of 12 notes in the octave.

Diaschisma of Euler, is the minor comma, $\frac{2025}{2048}$, $= 1C\,\Sigma + m$. See Comma minor: this is alſo the major dieſis of Maxwell.

Diaschisma of Dr. Buſby (Mus. Dict.) is an interval, the half of the minor ſemitone, $= 18\,\Sigma + \frac{1}{2}m + 1\frac{1}{2}m$, which exceeds $1\frac{1}{2}$ times the true diaſchiſma by $\frac{1}{2}f$.

Diaschisma of Boethius, is an interval equal to half a limma $= 23\,\Sigma + \frac{1}{2}f + 2m$; this interval has alſo been called by the ſame author the half dieſis, or ſemitone minor.

DIASCORDIUM, in *Pharmacy*, a kind of electuary, firſt deſcribed by Fracaſtorius, and denominated from ſcordium, which is a chief ingredient therein. It is alſo called confectio Fracaſtorii.

The other ingredients are red roſes, bole, ſtorax, cinnamon, caſſia lignea, dittany, tormentil roots, biſtort, gentian, galbanum, amber, terra ſigillata, opium, long pepper, ginger, mel roſatum, and Malmſey wine.

DIASEBESTEN, a purgative electuary, made with ſebeſtens and other ingredients, but now obſolete.

DIASENNA, a ſoft, purgative electuary, thus called from ſenna, which is its baſe.

The other ingredients are ſugar-candy, cinnamon, lapis lazuli, ſilk, cloves, galanga minor, black pepper, nardus Indica, ſeed of baſilicum, flowers of cloves, cardamoms, ſaffron, ginger, zedoary, roſemary flowers, long pepper, lapis Armenus, and honey.

DIASHENKIR, in *Geography*, a town of Aſiatic Turkey, in the province of Caramania; 6 miles N. W. of Kir-Shehr.

DIASIA, Διασια, in *Antiquity*, a feſtival at Athens in honour of Jupiter, ſurnamed Μειλιχιος, i. e. the *propitious*. Pott. Archæol. lib. ii. chap 20.

DIAST, in *Geography*, a town of Egypt; 3 miles N. of Manſoura. This ſmall town is a day's journey diſtant from St. Gemiane, where the Copti go in pilgrimage. At the time of that feſtival the plain is covered with tents. The Chriſtians and Mahometans promiſcuouſly rejoice together for eight days. They have horſe-races; the dancing girls aſſemble in great numbers; and Bacchus and Venus preſide at the entertainment.

DIASTASIS, from διιστημι, *I ſet apart*, a word uſed by the writers in *Medicine* in many different ſenſes. It is frequently uſed as a name for that ſeparation of the bones, when they naturally recede from one another. Sometimes it is uſed as the term for an interſtice, as that between the ulna and radius, or between the tibia and fibula. Sometimes it is put for a diſtention of the muſcles in convulſions; and, when applied to the ſtomach, it is made to ſignify an inclination to vomit.

DIASTEM, Diastema, in *Muſic*, a name the ancients gave to a ſimple interval, in contradiſtinction to a compound interval, which they call a ſyſtem.

Ariſtoxenus enumerates many differences of intervals: ſuch as greater or leſs; conſonant or diſſonant; compounded or uncompounded; related to one genus or to another; laſtly, rational or irrational. Ariſtox. ap. Wallis. Append. ad Ptolem. Harmon. p. 154.

Muſicians divide intervals into two kinds: one of them called ſyſtem, which is to contain at leaſt two intervals in any kind of muſic whatever; but may contain more. The other, called diaſtem, is a mere, or ſingle interval; the proper ſignification of the Greek διαστημα, being *interval*.

DIASTOLE, in *Anatomy*, (from διαστελλω, *I ſeparate*,) is the dilatation of the cavities of the heart, or of the arteries, by the influx of blood *ſeparating* their ſides, which were previouſly in contact. It is oppoſed to *ſyſtole*, or the contracted ſtate of the ſame cavities and tubes. See Circulation.

Diastole, in *Grammar*, a figure whereby a ſyllable naturally ſhort is made long.

Thus it is that Virgil begins a verſe with the word *Italus*, the firſt ſyllable whereof is naturally ſhort.

DIASTYLE, from δια. and στυλος. *a pillar*, in the *Ancient Architecture*, an edifice, where the columns ſtand at ſuch a diſtance from one another, that three diameters, or ſix modules, are allowed for the intercolumniation.

DIASURMUS, Διασυρμος from δια, and συρω, *I draw*, in *Rhetoric*, a figure whereby we ſhortly anſwer, or rather evade, a thing which it would be tedious to reply to in form.

E. gr. "*What matters it to reply to an argument foreign to the purpoſe?*"

DIATESSARON, in the *Greek Muſic*, is the interval or concord of the 4th, which is the 3d conſonance in perfection. (See Fourth.) The Greek word is compoſed of δια τεσσαρων, as the interval conſiſts of 4 diatonic degrees.

DIATESSARONARE, a barbarous Latin word uſed by all muſicians, and other old writers on muſic, for diſcant in 4ths.

DIATHESIS, in *Medicine*, ſignifies any general condition of the habit of body: thus, phyſicians ſpeak of the phlogiſtic or inflammatory diatheſis, which conſiſts in a general fullneſs and ſtrength of the body, and of the arterial ſyſtem in particular, which renders a perſon liable to inflammatory diſeaſes,

DIATONIC, *Adj.* The diatonic genus is the moſt natural and ſimple in muſic; it conſiſts of tones and major ſemitones, and in the ſcale of which genus the ſmalleſt interval is a conjoint degree, which changes its name and place. The word comes from δια, *through*, and τονος. *tone*, that is, paſſing from one tone to another: "God ſave great George our King," and "Let ambition fire thy Mind," are almoſt the only two Engliſh airs that are ſtrictly diatonic: *i. e.* totally without modulation by an accidental ♭ or ♯.

DIATONICO-GENERE, one of the three genera in the ancient Greek muſic, and which in modern muſic implies a ſcale of ſounds, conſiſting of a mixture of tones and ſemitones.

The Greek diatonic genus, or tetrachord, proceeded by a ſemitone, and two tones, as B C D E and it was from the ſucceſſion of two tones, that this genus acquired the name of diatonic. As the term is derived from δια, *by*, and τονος, *tone*; that is, paſſing from one tone to another; which in the Greek muſic was never done but in the diatonic genus.

DIATONUM, Διατονον, is uſed for the diatonic genus. See Diatonic.

Diatonum, is a term uſed by M. Henſling for the ſemitone major $\frac{15}{16} = 57\,\Sigma + f + 5\,m$.

DIATRÆTA,

DIATRÆTA, a word uſed by Pliny, and other of the ancient Romans, to expreſs a ſort of cups and vaſes which were of great value, and only ſeen at the tables of the great. They were pellucid and colourleſs, and cut into various forms, and were often engraven upon with figures expreſſive of the deeds of honour of the family who poſſeſſed them. The firſt diatrætæ were made of pure cryſtal of the rock, and the working of theſe rendered them very expenſive; but afterwards they were made of common white glaſs, and ſunk greatly in their price and value. The ancients were very nice in their diſtinctions of the ſeveral kinds of cryſtal. They termed the pureſt and fineſt of all acentatum, and the others, which were ſubject to blemiſhes and foulneſſes of ſeveral kinds, they called by names expreſſive of them. There was nothing they ſo much feared in the pieces they ſelected for this work, as what they called an over-hardneſs, that is, a brittleneſs, which made the veſſel often fly under the engraver's tool, after it had been formed into ſhape at a great expence: for this reaſon they were cautious of uſing the very brighteſt and cleareſt maſſes; for they often found thoſe ſucceed beſt, which had ſome of thoſe flaws which we call hairs in them. Theſe they thought the toughеſt pieces of cryſtal, and theſe flaws they eaſily concealed among the ſtrokes of their work. See NUBES and SAL.

DIATRAGACANTH, in *Pharmacy*, an obſolete preparation with gum tragacanth and other emollients. It is now ſuperſeded by the pulvis tragacanthæ compoſitus.

DIATRIBE, from διατριβω, *I delay*, denotes a continued diſcourſe.

DIATYPOSIS, διατυπωσις, in *Rhetoric*, the lively deſcription of a thing, ſetting it, as it were, before the eyes of the audience. Thus Cicero, vii. in Ver. "Ipſe inflammatus ſcelere, & furore, in forum venit; ardebant oculi; toto ex ore crudelitas eminebat, &c."

DIAUGOPHRAGMIA, in *Natural Hiſtory*, a genus of ſeptariæ, whoſe ſepta are of ſpar, with an admixture of cryſtal, which being ſometimes alſo mixed among the matter of the tali, renders the whole more bright and gloſſy. See SEPTARIÆ.

Of this genus we have the following ſpecies: 1. The ferrugineous red diaugophragmium, with browniſh yellow partitions. 2. The browniſh yellow diaugophragmium, with whitiſh partitions. 3. The blueiſh white diaugophragmium, with ſtraw-coloured partitions. Vide Hill, Hiſt. Foſſ. p. 522.

DIAULION, from δια, and αυλος, a *flute*, in *Antiquity*, a deſignation given to a performance on the ancient ſtage with the flute alone.

DIAULODROMI, Διαυλοδρομοι, from διαυλος, and δρομος, thoſe racers who turned round the meta, or goal, and finiſhed their courſe at the career-barrier, or place of ſtarting. The diaulodromi always took a ſhort breathing or reſt, when they arrived at the meta, before they ſet out again for the career.

DIAULOS, from δις, *twice*, and αυλη, *ſtation*, the name of a particular kind of foot-race, wherein the racers always returned to the place from whence they ſtarted, and were called diaulodromi. This was added to the other games in the 14th olympiad.

DIAULOS is uſed to ſignify a diſtance of two ſtadia, which was the length of the courſe in the race of this name.

DIAVOLO, in *Geography*, an iſland in the Grecian Archipelago. N. lat. 37° 17'. E. long. 23° 12'.

DIAZ, BARTHOLOMEW, in *Biography*, a diſtinguiſhed Portuguese navigator, who claims a ſhort notice as the diſcoverer of the Cape of Good Hope. He was employed by king John II. of Portugal, in proſecuting diſcoveries on the coaſt of Africa, and in 1486 he had traced nearly a thouſand miles of new country, and after encountering violent tempeſts, and loſing the company of the victualling veſſel which attended him, he came in ſight of the Cape, that terminates Africa; but the ſtate of his ſhip, and the untoward diſpoſition of his crew, obliged him to return without going round it. He named it, on account of the troubles which he had undergone in the voyage, "Cabo Tormentoſo," or the "Stormy Cape." He returned to Liſbon in December 1487, and from his report the ſovereign foreſaw that the courſe to the Indies was now certainly pointed out, and he denominated the newly-diſcovered point "Cabo del Bueno Eſperanza," or the "Cape of Good Hope." Robertſon's America.

DIAZEUTIC TONE, in *Muſic*, ſignifies the interval of the major tone $\frac{8}{9}_1 = 104\,\Sigma + 2\,f + 9\,m$.

DIAZEUXIS, a Greek muſical term, which implies diviſion, ſeparation, disjunction.

The note which ſeparates two tetrachords was thus called in the ancient muſic, and which, added to either, formed a diapente. It is the tone major of the moderns in the ratio of eight to nine, and which is in effect the difference between the 4th and 5th of a key.

The diazeuxis, in the Greek muſic, was between the meſe, and parameſe: that is to ſay, between the higheſt note of the ſecond tetrachord, and the loweſt of the third; or between the note ſynnemenon, and the parameſe hyperbolæon; or between the 3d and 4th tetrachord, according to the place where the disjunction happens; for it is impracticable at the ſame time in both. The homologous ſtrings of the two tetrachords, between which the diazeuxis lies, form a 5th; whereas, they form a 4th when conjoined.

DIAZIMUM, in *Ancient Geography*, a part of Cappadocia, in which was ſituated the town of *Amaſia*.

DIB, in *Ichthyology*, a variety of the SCIÆNA *Ramak*, which ſee.

DIBBI, or DARK *Lake*, a lake of Africa, at the diſtance of two days journey beyond the town of Jenne; in croſſing which, from weſt to eaſt, the canoes are ſaid to loſe ſight of land for an entire day. From this lake the river runs in ſeveral ſtreams, forming two large branches, which join at Kabra, one day's journey ſouth of Tombuctoo, and the port of that city or town.

DIBBLE, in *Agriculture*, the name of an implement or tool made uſe of for the purpoſe of making holes in the ground for ſetting grain, plants, and other ſorts of crops in, which are planted in rows. They are formed of different materials, and in different ways, according to the nature of the crop which is to be put in or planted out by them, but for grain they are moſtly ſhod with iron. In ſome caſes they have likewiſe a ſort of ſtep for ſetting the foot upon, in uſing them. When employed, they are thruſt into the ground to a depth ſuitable to the crop which is to be put in by them, and holes thus formed, into which the ſeeds, ſets, or plants, are put by the hand.

DIBBLE, in *Gardening*, a ſort of tool which is made uſe of for ſetting and planting out different kinds of ſeeds, roots, plants, and cuttings. They are moſtly made of the handles of old ſpades, having the handle parts left entire, and the ſhanks twelve or fifteen inches in length, gradually tapering to points at the lower ends; and to render them more complete, they are often ſhod with a thin ſocket of iron, ſeven or eight inches in length, made tapering to the point. Dibbles thus ſhod are found to make the holes more eaſily, in a more clean manner, and with greater expedition, than thoſe which are wholly of wood, which are apt to clog with the earth, and retard the buſineſs of planting.

Theſe tools, when intended for planting broad beans, potatoes, and large ſorts of roots, ſhould be made with blunt points, as by being rounded at the ends the holes are ſo formed as to admit them to the bottom; while the narrow pointed ones, by making the holes deeper than are neceſ-

ſary, ſo as to leave vacancies or openings below the ſeeds or roots, they are liable to permit water to ſtagnate below them, and thus prove injurious, eſpecially in the winter ſeaſon. And beſides, where the ſeeds or roots reſt upon the bottoms of the holes, the growth of the plants is moſtly more perfect and complete.

All the different kinds of bulbs, as thoſe of the crocus, narciſſus, tulip, &c. require this form of dibble in planting them out.

DIBBLER, in *Agriculture*, a perſon who is employed in the buſineſs of dibbling or ſetting of crops by means of the dibble.

DIBBLING, the operation or proceſs of ſetting corn, ſeed, or other crops, by the dibble. It is chiefly practiſed in the putting in of wheat crops, and thoſe of the pulſe kind, in thoſe diſtricts in which labour is cheap. This practice was known at an early period, but was afterwards neglected, until the attention of the farmer was again drawn to it, by the writings of Mr. Varlo and ſome others.

The author of Modern Agriculture remarks, "that the method of dibbling, or ſetting wheat by the hand, was firſt introduced into Norfolk about twenty years ago, by a perſon who poſſeſſed a ſmall farm in the neighbourhood of Norwich; and that this practice, which gradually gained ground in that diſtrict, has now become pretty general in the adjoining counties of Cambridge and Suffolk. In both of theſe, as well as in the county of Norfolk, conſiderable quantities of wheat are annually ſet by hand; but, in the laſt, where the method was firſt adopted, the quantity of wheat now planted by hand is not nearly ſo conſiderable as it was a few years ago. The wheat is generally dibbled in October, on land newly broken up from clover-ley. When the ſoil is of a light nature, it is uſually rolled before the ſeed is planted; the method of which is as follows: a man with an iron dibble, about three feet long, in each hand, walking backward and making two rows of holes in each furrow, ſlice, or flag; they are made about four inches diſtant from each other, and from one to two inches deep. The dibbler is followed by two or three women, boys, or girls, who drop two or three grains into each hole. The field is afterwards buſh-harrowed, by fitting thorns to a gate, and drawing it by one horſe along the furrows. The uſual quantity of ſeed is about ſix or ſeven pecks, and the expence of ſetting from nine to ten ſhillings the acre. An experienced dibbler, with three active attendants, will plant half an acre a day, making ſix holes in every foot length along the furrow-ſlice. The advocates for dibbling wheat ſtate ſeveral advantages which, in their opinion, reſult from adopting this method in preference of the ordinary one, ſowing broad-caſt. They ſay a conſiderable quantity of ſeed is ſaved, that the grain is better, more equal in quality, and the increaſe greater; and further, that by the general eſtabliſhment of this practice the poor would find employment. There is no doubt but that a conſiderable ſaving muſt take place in the article of ſeed, when the grains are dropt at regular diſtances, in place of being ſcattered promiſcuouſly. The quantity is ſaid to be, in general, about a buſhel the acre. Were no other benefit derived from adopting this practice than ſaving a buſhel of ſeed on the acre, that, at the ordinary price of wheat, is more than counterbalanced by the extra expence incurred. The farmer, in order to ſave this buſhel of wheat, value five or ſix ſhillings, muſt pay his labourers nine or ten. On this principle, therefore, the practice cannot be defended. It is natural to ſuppoſe, and will be readily admitted, that a crop of planted wheat will always be to a certain degree better, and more equal in quality, and (although from that circumſtance probably, chiefly) greater in quantity, than that ſown broad-caſt. The crop, ſpringing up at regular diſtances, enjoys, during the whole period of its growth, a more free circulation of air, and derives greater benefit from the rays of the ſun, than when, by ſowing the ſeeds too thick or irregularly, the plants ſtand ſo cloſe together that both are in a great meaſure excluded. There is another reaſon why the grain ſhould be of a better quality. It was obſerved, that wheat is commonly dibbled on land broken up from one year's clover. When wheat is ſown broad-caſt on ſuch lands, a great many of the ſeeds fall naturally into the interſtices of the furrows, where they are either choaked, or retarded in their growth, by the weeds, which ſpring up there in greater abundance than in the other parts of the fields: whereas, when the ſeeds are ſet in the ſlice or flags, the plants cannot meet with any impediment to retard their growth. Although, for theſe reaſons it is highly probable that the produce of dibbled wheat muſt always be ſuperior in quality and quantity to that ſown broad-caſt; yet, without repeated experiments, or the eſtabliſhment of a law whereby all grain ſhall be ſold by weight, it is impoſſible to determine the extent of that ſuperiority, or whether ſo much advantage reſults therefrom as to encourage farmers in other parts of the kingdom, if practicable, to adopt the ſame method. Some people have gone ſo far as to aſſert, that dibbling wheat is one of the greateſt improvements in modern agriculture; and that owing chiefly to the circumſtances of its furniſhing work for the poor. In a populous diſtrict, where agriculture is almoſt the only employment of the inhabitants, and where the poor-rates have advanced to an extravagant height, the introduction of any practice whereby the poor can be uſefully employed, while the individuals who furniſh that employment, if they are not benefited, are not injured thereby, muſt be deemed a very eſſential improvement. Dibbling wheat, therefore, in diſtricts ſo ſituated, eſpecially if followed out by hand-hoeing, ſo as to afford ſtill longer work, may be a very proper way of furniſhing employment for the peaſantry. But the writer thinks, in a country like Great Britain, where the great body of the people are alternately employed in warfare, or in commerce and manufactures, and the ordinary operations of huſbandry, the impracticability of rendering this a general practice muſt be at once obvious. The population muſt, indeed, be amazingly increaſed before that can happen. Populous as this iſland now is, beyond what it was at any former period, yet, were a law enacted, that all grain ſhould be planted by hand, it would be neceſſary that all ranks, the governors as well as the governed, ſhould learn how to uſe the dibble. In a word, although the practice may be beneficial as well as laudable, in ſome particular diſtricts, no perſon in his ſober ſenſes will, he aſſerts, think of recommending the general eſtabliſhment of it, as an improvement in the national agriculture.

The author of the Report of Suffolk remarks, that "for wheat in ſome diſtricts a narrow-ſet plough of only ſeven inches width at bottom, is uſed to plough with; a one horſe roll then follows to level the flag, or furrow, for the dibblers who ſtrike only one row upon each: when the wheat is depoſited, two or three kernels in each hole, a two horſe-roll follows, and afterwards the harrows twice in a place; when the field is finiſhed in this manner, it is harrowed up again obliquely: by this method the wheat is depoſited in the middle of the flag, at the diſtance of nine inches in the row, and when come up, has the appearance of being drilled; the two-horſe roller is ſuppoſed of material uſe in cloſing up the holes, and preventing the wheat from being diſturbed by harrowing, and the land is made ſo ſolid by rolling, that very little apprehenſions are entertained about the ſlug or worm. If there ſhould be occaſion to hoe in the ſpring, the operation can
